CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

NEW EDITION

Edited by

DAVID PATRICK, M.A., LL.D.

AND

WILLIAM GEDDIE, M.A., B.Sc.

VOLUME VI

HUME TO MANCHE

W. & R. CHAMBERS, LIMITED
LONDON and EDINBURGH

J. B. LIPPINCOTT COMPANY PHILADELPHIA

1926

All Rights Reserved

Among the more important articles in this Volume are the following:

HUME, DAVID.....	J. HILL BURTON.	KEBLE.....	Rev. Professor W. LOCK.
HUNT, LEIGH.....	F. HINDS GROOME.	KEPLER.....	Rev. E. B. KIRK.
HUSBAND AND WIFE...	Sheriff J. M. IRVINE, K.C., LL.D.	KIN, KULTURKERREIS.....	NORTHCOOTE W. THOMAS.
HYDRODYNAMICS.....	Professor CARRILL G. KNOTT.	KINGSLEY.....	ULICK BURKE.
HYDROGEN.....	Dr L. DOBBIN.	KNOX.....	Professor P. HUME BROWN, LL.D.
HYDROPHOBIA.....	M. PASTEUR and Prof. JAS. RITCHIE.	KUFIC COINS.....	Professor STANLEY LANE-POOLE.
HYGIENE.....	Sir W. LESLIE MACKENZIE.	LACE.....	JAMES PATON.
HYMN.....	Rev. JOHN JULIAN.	LAFONTAINE.....	WALTER WHYTE.
HYPNOTISM.....	Dr R. W. FELKIN.	LAMAISM, LHASA.....	Dr W. M. MCGOVERN.
HYSTERIA.....	Sir JOHN MACPHERSON.	LAMB, CHARLES.....	Canon AINGER.
I; J; K; L; M.....	Dr HENRY BRADLEY.	LAND LAWS; LAND-	
IBSEN.....	WILLIAM ARCHER.	LORD AND TENANT...	Sheriff J. M. IRVINE, K.C., LL.D.
ICELAND.....	JÓN A. HJALTALÍN.	LAO-TSZE.....	Professor LEGGE.
IGNEOUS ROCKS, &c.....	Professor JAMES GEIKIE.	LARYNX.....	Dr W. G. PORTER.
ILLUMINATION.....	HENRY B. WHEATLEY.	LASSALLE.....	THOMAS KIRKUP.
ILLUSTRATION.....	J. R. FAIRMAN; W. B. HISLOP.	LATIN; LUCRETIUS.....	Rev. W. J. BRODRIBB.
IMAGE.....	W. J. PERRY.	LATITUDE AND LONGI-	
INDEPENDENTS.....	Rev. E. SILVESTER HORNE.	TUDE.....	HUGH ROBERT MILL, D.Sc.
INDEXING.....	HENRY B. WHEATLEY.	LEAD.....	Professor HENRY BRIGGS.
INDIA.....	Sir RICHARD TEMPLE, G.C.S.I., D.C.L.	LEAF.....	Professor PATRICK GEDDES.
INDIAN OCEAN.....	Sir JOHN MURRAY.	LEAGUE OF NATIONS...	Professor GILBERT MURRAY; H. WIL-
INDIGO.....	Professor A. A. BOON.		SON HARRIS.
INSANITY.....	Sir T. S. CLOUSTON; Sir JOHN MAC-	LEE, GENERAL.....	N. B. WEBSTER.
	PERKINSON.	LEEDS.....	S. B. TAIT.
INSECTS.....	Professor J. A. THOMSON.	LEIGHTON.....	THOMAS DAVIDSON.
INSURANCE.....	GEORGE KING, F.S.A.; G. S. W. EPPS.	LEONARDO DA VINCI...	J. M. GRAY.
INTERNAL COMBUSTION		LE SAGE.....	JOHN ORMSBY.
ENGINE.....	Professor F. BACON.	LESSING.....	J. T. BEALBY.
INTERNATIONAL LAW...	Sheriff J. M. IRVINE, K.C., LL.D.	LIBEL.....	FRANCIS WATT.
IRELAND.....	JUSTIN MCCARTHY; Prof. MACKIN-	LIBRARY.....	F. C. NICHOLSON.
	NON; Prof. G. T. STOKES, D.D.	LICENSING LAWS.....	Rt. Hon. LEIF JONES.
IRON AND STEEL.....	Professor J. O. ARNOLD, F.R.S.; Dr	LIFE.....	Professor J. ARTHUR THOMSON.
	F. LIDBOMSON.	LIFEBOAT; LIFE-SAV-	
IRVING, WASHINGTON. F. H. UNDERWOOD, LL.D.		ING APPLIANCES.....	J. R. BARNETT.
ISAAH.....	Very Rev. Principal Sir G. A. SMITH.	LIGHT; LENSES.....	Dr ALFRED DANIELL.
ISLAND.....	HUGH ROBERT MILL, D.Sc.	LIGHTHOUSE.....	D. & C. STEVENSON.
ISOGATHES; IHUSUS.....	Professor F. B. JEVONS.	LIGHTNING.....	R. T. OMOND.
JACKSON, ANDREW.....	Professor J. P. LAMBERTON.	LINCOLN, ABRAHAM.....	Professor J. P. LAMBERTON.
JADE; JET.....	Dr ROBERT CAMPBELL.	LINGUISTICS.....	H. O. COLEMAN.
JAMES I.....	JOHN RUSSELL.	LION; LEOPARD.....	F. E. BEDDARD, F.R.S.
JAPAN.....	Professor DIXON; J. H. GUBBINS.	LIQUOR LAWS.....	Rt. Hon. LEIF JONES.
JEFFERSON, THOMAS...	Professor N. B. WEBSTER.	LISZT.....	COLIN STALKER.
JERROLD, DOUGLAS.....	WALTER JERROLD.	LITHOGRAPHY.....	J. R. FAIRMAN; W. B. HISLOP.
JERUSALEM.....	Dr E. W. G. MASTERMAN.	LITURGY; LITANY.....	MARQUIS OF BUTE.
JEST-BOOKS.....	W. A. CLOUSTON.	LIVERPOOL.....	Professor RAMSAY MUIR.
JESUS CHRIST.....	Rev. Professor II. T. ANDREWS, D.D.	LIVERWORTS.....	GEORGE WENT.
JERWS.....	EMM. DEITCH; ISIDORE HARRIS;	LIVINGSTONE.....	Professor W. G. BLAIKIE, D.D.
	HERBERT LOEWE.	LOCKE.....	Professor A. CAMPBELL FRASER.
JOB; JOHN.....	Rev. Professor II. T. ANDREWS, D.D.	LOGARITHMS.....	Professor WILLIAM PEDDIE.
JOHNSON, ANDREW.....	Hon. FREDERICK W. SEWARD.	LOGIC; LOTZE.....	Professor PRINGLE PATTISON.
JOHNSON, SAMUEL.....	Professor HALES.	LONDON.....	Rev. W. J. LOFTIE; C. O. OYINGTON.
JULIAN.....	THOMAS DAVIDSON.	LONGFELLOW; LOWELL	F. H. UNDERWOOD, LL.D.
JUNIOR.....	W. FRASER RAE.	LUTHER.....	Principal TULLOCH.
JURY; LAW.....	Sir THOS. RALEIGH, K.C.S.I., D.C.L.	LYLY, JOHN.....	A. H. BULLEN.
JUSTICE OF PEACE.....	Sir A. WOOD RENTON.	LYTTON, BULWER.....	F. HINDS GROOME.
JUSTINIAN.....	Professor HENRY GOUDY, D.C.L.	MACAULAY.....	WILLIAM WALLACE, LL.D.
JUTE; LINEN.....	ALAN. GALLAGHER; PETER-KILGOUR.	MACHIAVELLI.....	SIGNORA CANTAGALLI.
JURNAL; JUCAN.....	Dr J. P. STUBBLE.	MACHINE GUN.....	Colonel Sir H. W. BARLOW, Bt.
KABUL; KASHMIR.....	Colonel Sir T. H. HOLDICH, K.C.M.G.	MADAGASCAR.....	Rev. JAMES SIBREE, D.D.
KALMYCKS; KIRGHIZ..	Professor E. H. PARKER.	MAGIC.....	W. J. PERRY.
KANT.....	JAMES HUTCHINSON STIRLING, LL.D.	MAGNETISM.....	Dr ALFRED DANIELL.
KRAN; KREMBLE.....	ROBERT W. LOWE.	MALARIA.....	Sir RONALD ROSS, K.C.B., F.R.S.
KEATS.....	F. T. PALGRAVE.	MAMELUKES.....	HERBERT LOEWE.

A great many of the articles named above are new; others written for earlier issues of this Encyclopædia have been so thoroughly revised by their authors as to be virtually new. In addition to these many other revisers have taken part, including Mr GEORGE WENT (Botany), Dr DRINKWATER (Chemistry), Dr ROBERT CAMPBELL (Geology), Mr G. E. SHEPHERD (India), Father THURSTON (art. JESUITS), Mr W. A. FLEMING, Advocate, and Mr NORMAN MACDONALD, Advocate (Law), Dr J. D. COMBIE (Medicine), Dr S. A. COOK (Old Testament), Professor J. ARTHUR THOMSON (Zoology). Thanks are due for information supplied by Mrs JUNG and Dr H. GODWIN BAYNES (art. JUNG), to Mr V. K. RACKAUSKAS, Secretary of the Lithuanian Legation (art. LITHUANIA), and to various town clerks; as well as to Mr JAMES GRAHAM and Mr RHODES K. CALVERT, who read proofs of LEEDS.

CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

HUME, DAVID, philosopher and historian, was born at Edinburgh on the 26th of April 1711 (O.S.). His father was the laird or proprietor of the estate of Ninewells, in Berwickshire, but David, being the younger son, had to make his own fortune with no other assistance than

an education and the influence of his respectable family. He was educated at home and at the university of Edinburgh. His father designed law as his profession, and he submitted to the initial steps of the proper practical training, but it was not a pursuit to his liking. Deserting it, he made experiment of a mercantile life in Bristol; but commerce was not more congenial to him than jurisprudence, and he gave it a very short trial. He now became a student, devoting himself to books with no settled practical object before him. He has recorded his sufferings at this time from despondency and depression of spirits, caused apparently by the effects of monotonous study. At twenty-three years of age he went to France and lived some time in La Flèche, where he describes himself as wandering about in solitude, and dreaming the dream of his philosophy. In 1739 he published the first and second books of his *Treatise on Human Nature*—the germ of his philosophy, and still perhaps the best exposition of it, since it has there a freshness and decision approaching to paradox, much modified in his later works. Although the dawn of a new era in philosophy, this book was little noticed; in his own words, 'it fell dead-born from the press.' It was a work of demolition. By separating the impressions or ideas created on the thinking mind by an external world from the absolute existence of that world itself he showed that almost everything concerning the latter was taken for granted, and he demanded proof of its existence of a kind not yet afforded. It was thus that he set a whole army of philosophers at work, either to refute what he had

said, or seriously to fill up the blanks which he discovered: thus he gave the original impulse both to the Scottish school of philosophy—Reid, and the rest—and to Kant's speculations. In 1741 and 1742 he published two small volumes called *Essays Moral and Political*; they were marked by learning and thought, and elegantly written, but are not among the more remarkable of his works.

He felt keenly at this time the want of some fixed lucrative pursuit, and his longing for independence was the cause of a sad interruption to his studious and philosophical pursuits. He was induced to become the companion or guardian of an insane nobleman, and had to mix with the jealousies and mercenary objects of those who naturally gather round such a centre. In 1746 he obtained a rather more congenial appointment as secretary to General St Clair, whom he accompanied in the expedition to the coast of France and the attack on Port l'Orient, the depôt of the French East India Company; this affair had no important results, but it gave Hume a notion of actual warfare. In 1748 he accompanied the general in a diplomatic mission to Vienna and Turin, and as he travelled he took notes of his impressions of Holland, Germany, and Italy, which are published in his *Life and Correspondence*.

In 1751 he published his *Inquiry into the Principles of Morals*, a work of great originality, and one of the clearest expositions of the leading principles of what is termed the utilitarian system. At the same time he intended to publish his *Dialogues concerning Natural Religion*; but his friends, alarmed by the sceptical spirit pervading them, prevailed on him to lay them aside, and they were not made public until after his death. In his thirty-fifth year he had unsuccessfully competed for the chair of Moral Philosophy in Edinburgh, and at this period we find him unsuccessful in an attempt to obtain the chair of Logic in Glasgow. Next year, in 1752, appeared his *Political Discourses*. Here, again, he made an era in literature, for in this little work he announced those principles of political economy, comprehending the doctrine of

free trade, which it fell to his friend Adam Smith more fully and comprehensively to develop. He was appointed at this time keeper of the Advocates' Library, with a very small salary, which he devoted to a charitable purpose. It was here that, surrounded with books, he formed the design of writing the history of England. In 1754 he issued a quarto volume of the *History of the Stuarts, containing the Reigns of James I. and Charles I.*, and presently completed this portion of the work in a second volume, bringing it down to the Revolution. The second volume attracted more notice than the first had done. He then went backwards through the House of Tudor, and completed the work from the Roman period downwards in 1762. While so employed he published *Four Dissertations: the Natural History of Religion; of the Passions; of Tragedy; of the Standard of Taste* (1757). Two other dissertations, intended to accompany these, were cancelled by him after they were printed—they are *On Suicide* and *The Immortality of the Soul*, and were subsequently printed in his works.

In 1763 he went to France as secretary to Lord Hertford's embassy; here he was in his element, and found fame at last. He became familiar with the brilliant wits and savants of the Parisian circle—with Turgot, D'Alembert, Helvetius, Holbach, Diderot, Buffon, Malesherbes, Crebillon, and the rest, as well as with the hardly less distinguished women, De Boufflers, Du Deffand, and L'Espinasse. His sojourn in Paris was unfortunate in bringing him into intimacy with the restless, vain, and self-tormenting Rousseau, who, after experiencing much substantial kindness from Hume, got suspicious, and forced him into a memorable quarrel. After his return home, in 1766, he accepted the responsible office of Under-secretary of State for the Home Department. In his own Life he says: 'I returned to Edinburgh in 1769 very opulent (for I possessed a revenue of £1000 a year), healthy, and, though somewhat stricken in years, with the prospect of enjoying long my ease, and of seeing the increase of my reputation.' His health gave way in 1774, and he died at Edinburgh, 25th August 1776.

Hume is the outcome of the empirical philosophy of Locke. His philosophical writings do not form a system, but discuss many of the salient ideas of philosophy, mainly in a sceptical or destructive manner. Ideas are but weakened copies of 'impressions' of the senses, outer or inner; mind is a succession of isolated impressions and ideas; the idea of cause depends on the habit of mind which expects the event that usually follows on another, and there is no necessary connection between cause and effect. Hume's *History*, which gave him a high rank among English historical authors, was not remarkable for historic impartiality (in a later edition more than a hundred alterations on the reigns of the first two Stuarts were made by Hume himself, and all to the Tory side), and has been superseded. Hume's position in relation to his predecessors and successors is given under *BERKELEY*; the article *CAUSALITY* is largely concerned with the discussion of his views. For the influence of Hume's scepticism in awaking Kant from his dogmatic slumber, see *KANT*. The most important edition of Hume's works is that by T. H. Green and T. H. Grose (4 vols. 1874), with introduction and exhaustive analysis of Hume's philosophy. His *Life and Correspondence* was published by J. Hill Burton (2 vols. 1846); Dr G. Birkbeck Hill edited his *Letters to William Strahan*, with copious and valuable notes (1889). For his theological position, and his relation to Edinburgh society, complicated by his 'infidelity,' see Leslie Stephen's *English Thought in the Eighteenth Century* (1876), the autobiography of 'Jupiter' Carlyle, &c. There are short monographs by Huxley (1879), Knight (1886), and Calderwood (1898); and German works by Jodl (1872), E. Pfeiderer (1874), Gizycki (1878), and Thomsen (1912). See also Seth's *English Philosophers* (1912), and Sorley's *History of English Philosophy* (1920).

Hume, JOSEPH, politician, was born 22d January 1777, at Montrose. He studied medicine at Edinburgh, and in 1797 became assistant-surgeon in the service of the East India Company. He applied himself to the acquisition of the native languages, and during the Mahratta war, from 1802 to 1807, filled some half-dozen important offices, chief amongst which were those of interpreter and commissary-general. On the conclusion of peace he returned to England in 1808, his fortune made. Becoming imbued with the political philosophy of James Mill and Bentham, he gained admission to parliament, sitting as member for Weymouth, Aberdeen, Middlesex, Kilkenny, and Montrose successively, this last from 1842 to his death, which occurred on 20th February 1855. 'An uncompromising honesty, an instinctive hatred of abuses, an innate love of liberty, and an unflinching will to extend its benefits to others—these, and the close experience of men derived by himself during the earlier part of his life, rendered Mr Hume one of the most powerful, and at the same time one of the most practical, of reformers in a reforming age.' Amongst the schemes and reforms he advocated may be enumerated the establishment of savings-banks, freedom of trade with India, abolition of flogging in the army, of naval impressment, and of imprisonment for debt, repeal of the act prohibiting export of machinery, and of that preventing workmen from going abroad, reduction of election expenses, abrogation of duties on paper, and removal of abuses of all and sundry kinds whatsoever. He also took a leading part in the agitation against the supposed designs of the Orange lodges to make the Duke of Cumberland king on the decease of William IV.

Hume, SIR PATRICK (1641–1724), an eminent statesman and covenanter, Lord Chancellor of Scotland, who in 1690 was created Lord Polwarth, and in 1697 Earl of Marchmont. See *BAILLIE (LADY GRIZEL)*.

Humeral Veil, an oblong silk scarf worn by priests and sub-deacons round their shoulders at certain parts of the service of the Mass and of Benediction, and the carrying of the Viaticum. Save at the procession of the Blessed Sacrament and at the giving of Benediction, when only the hands are beneath the veil, the vessel containing the Host is also covered.

Humic Acid. See *APOCRENIC ACID*.

Hummel, JOHANN NEPOMUK, pianist and composer, was born at Pressburg, 14th November 1878. He first studied under Mozart, and then, after a seven years' concert tour in Germany, Denmark, England, and Holland, he returned to Vienna to complete his musical education under Albrechtsberger and Salieri. From 1803 to 1811 he held the post of musical director to Prince Eszterházy; and in 1816 he filled a similar position at Stuttgart, but moved four years later to Weimar, where he died, 17th October 1837. In the course of several musical tours he delighted the capitals of Europe with his pianoforte playing and his clever improvisations on that instrument. Of his musical compositions the only ones which have value at the present day are his pianoforte works.

Humming-bird, a Linnean genus (*Trochilus*) of birds, now constituting a family, Trochilidae. The nearest relations of the humming-birds are the Swifts (q.v.); that they form together with the swifts one large group is clear from their very close resemblances in anatomical structure. Nitzsch, Huxley, Garrod, and others who have investigated the osteology, muscular anatomy, and other points concur in this opinion as to the relationship of the family; they resemble in their habit and in brilliancy of plumage the Sun-birds (q.v.), which replace them

in the eastern tropical regions. The dazzling brilliancy of humming-birds, the extreme rapidity with which they dart through the air, their hovering above the flowers from which they obtain their food, with humming sound of wings, which move so quickly as to be indistinctly visible, or 'like a mist,' have attracted universal admiration since the first discovery of America. The diminutive size of almost all of them—some of them being the smallest of birds, and of stripped of their feathers not larger than a humble-bee—has still further contributed to render them objects of interest, whilst the plumage of the different species exhibits an almost endless variety of colours. Some species possess 'the most gorgeously brilliant metallic hues known among created things;' some on the other hand are sombre

a, Sword-bill Humming-bird (*Docimastes ensifer*);
b, White-booted Racket-tail (*Steganurus Underwoodi*);
c, c', male and female Tufted Coquette (*Lophornis ornata*).

in hue. Humming-birds are entirely confined to the American continent and West Indies, where there are about 120 genera, containing over 400 species; no less than 15 species occur in North America. Of the South American forms the majority inhabit the hotter regions, but some are confined to elevated mountain-tracts even above the snow-line.

Humming-birds have slender bills, which are also generally long, and in some extremely so, the form of the bill exhibiting a wonderful adaptation to the kind of flowers from which the bird obtains its food—straight in some, curved in others. Humming-birds do not, as was long supposed, feed on honey alone, but to a considerable extent, and some of them perhaps chiefly, on insects, not rejecting spiders, whilst they often snatch away the insects which have become entangled in spiders' webs. The tongue is very long, capable of being darted out to a considerable length; the bone of the tongue (hyoid bone) being much elongated, and its branches passing round the back of the skull to the forehead, where they meet in a point before the line of the eyes. The tongue itself consists of two hollow filaments, joined together for the greater part of their length, and separated at the tip; the structure of the tongue and hyoid bones is curiously like that of the Woodpeckers (q.v.) and the sun-birds already referred to; this affords an illustration of the fact that similar requirements often cause development of similar structures in animals otherwise distinct. The wings of humming-birds are very long and powerful, like those of the swifts, the length being particularly marked in that portion of

the wing which corresponds to the hand of mammals; hence the name *Macrochires* which is applied to the group. Humming-birds construct their nests with nice art, generally of lichens and of fibrous substances, such as cotton. They do not lay more than two eggs. They are very bold in defence of their nests and young, and are said to strike fearlessly with their needle-like bills at the eyes of birds of prey, which they far surpass in agility and rapidity of flight. They are very easily tamed and rendered familiar, and have been known to return again in spring, after a winter migration to a warmer climate, to the window from which they had been allowed to escape. Attempts to keep tamed humming-birds have generally failed; but lately they have been brought safely across and have lived for some time. Humming-bird skins were anciently used by the Mexicans for making pictures.

See John Gould's magnificent *Monograph on the Trochilidae* (5 vols. 1849). Gould's collection of specimens was bought for the British Museum.

Humming-bird Moth. See HAWK-MOTH.

Humours, Humoral Pathology. See TEMPERAMENT, HIPPOCRATES.

Humperdinck, ENGELBERT, composer, was born at Siegburg, near Bonn, 1st September 1854; and after studying music at Cologne, Munich, &c., and travel in France, Spain, and Italy, taught in the conservatoria of Barcelona, Cologne (1887), and Frankfurt (1890), and in a school of composition in Berlin (1900), and wrote music criticism. In Naples in 1879 he met Wagner, who summoned him to assist in the production of his only symphony; and it was Humperdinck who prepared the first cast of *Parsifal* at Baireuth (1882). He became famous as the composer of the prodigiously successful fairy-tale opera, *Hänsel und Gretel* (1894), a wholly happy application of Wagnerian methods to children's themes. It was followed by *Schneewittchen* and *Königskinder* (1897). In 1912 *The Miracle*, for which he had written the music, was produced in London, and in 1914 *Die Marktgendlerin* at Cologne. He died 27th September 1921 at Neu Strelitz.

Hums. See HEMS.

Humulus. See HOP, FIBROUS SUBSTANCES.

Humus. See SOILS.

Hunchback. See SPINAL COLUMN.

Hundred, in English law, an ancient subdivision of counties, the name of which probably arose from there being a hundred warriors, or perhaps a hundred families, or ten tithings, in each (see FEUDALISM). In ancient times, if a crime was committed, such as robbery, maiming of cattle, burning of stacks, &c., the hundred had to make it good. The old distinctions have, however, now less significance. Until the passage of the Riot Damages Act of 1886, when the hundred had a constable or bailiff, and when any damage was done by rioters feloniously destroying property, the owner had his remedy by suing the hundred for the damage. In order to secure this remedy the party or his servant must, within seven days, go before a justice, and engage to prosecute the offenders, when apprehended. So, where there was no hundred, the county, or city, or town was liable in like manner. Execution was levied on the treasurer of the county. In the northern counties a hundred was called a wapentake (Yorkshire) or a ward. See RIOT, COUNTY.—The townships in Delaware, U.S., are also called Hundreds. See also CHILTERN HUNDREDS.

Hundred Days, the period between Napoleon's landing in France after his escape from Elba (1st March 1815) and the battle of Waterloo (18th June 1815). See FRANCE, NAPOLEON I.

Hungary (Hung. *Magyarország*, Ger. *Ungarn*, Lat. *Hungaria*), is a kingdom of central Europe, formerly the larger part of the dual monarchy of Austria-Hungary, with an area of 125,000 sq. m., but now, as a result of the Great War, only a remnant of its previous size, with an area of 36,000 sq. m. It lies between 45° 75' and 48° 50' N. lat., and between 16° 30' and 22° 80' E. long. The territories of the old kingdom most valuable in minerals and oil-fuel have been given to the neighbouring countries—Rumania, Czechoslovakia, and Yugoslavia—while its natural physical boundaries have given place to ill-defined lines dividing differing nationalities, which are as follows: to the north, the Danube east of Pressburg, then the Ipoly, whence the line runs, without heed to natural features though in a generally easterly direction, through hills and valley lands; on the east a south-westerly line to Makó; and on the south across the Alföld till it meets the Drava, whose course it follows upwards to the confluence with the Limbach (Lendva); the western frontier runs north-east to the Neusiedlersee (Fertő Tava), making a loop round the Oedenburg or Sopron salient (which went by plebiscite to Hungary when the rest of Burgenland was ceded to Austria), and thence north to Pressburg. Hungary consists almost entirely of a vast and very fertile plain, with an average elevation of from 300 to 350 feet. The river Danube, flowing from the north at Budapest almost due south, divides the country into two very nearly equal parts. To the east the land rises gradually to the slopes of the Carpathian plateau, and thence to the mountains. To the west the country is low-lying, and in many places swampy, developing into Lakes Balaton (48 miles by 8 miles) and Székesfehérvár.

Rivers.—Hungary is well watered, having, in addition to the Danube (Duna), the Theiss (Tisza), with its tributaries, the Körös, Bodrog, Hernád, Sajó, and Zagyvad, flowing from the north-eastern frontier across the Alföld to Szeged on the south central boundary. On the west of the Danube are the Drava, with its tributaries, flowing south-east, and the Raab, Marczal, Repcze, and Czancza, flowing north—all tributaries of the mother-stream of the country, the Danube.

The only mountains are to the north in small, scattered groups, such as Matra, Bukk, Bakony Forest, Vértes, and Hegyalja.

Population.—Hungary had a population of 7,987,144 in 1920, which, in comparison with its 20,886,487 in 1910, shows how it has been shorn of territory. The population, which in 1910 included 9,900,000 Magyars (Hungarians proper), now has 7,147,050, so that it will be seen that not even the national population is left entirely to the present state. The remainder has been distributed through the neighbouring states, where, although in the minority, they exercise a considerable influence. In 1921 the population of Hungary was 89.6 per cent. Magyar, 7 per cent. German (551,211), 1.8 Slovakian (141,882), and included also 36,858 Croatsians, 23,000 Rumanians, and 17,000 Serbians. According to religion, over half are Roman Catholics, while Calvinists, Lutherans, and Jews make up the remainder. The greater proportion, nearly 72 per cent., live in villages, while some 28 per cent. live in towns of over 10,000 inhabitants. During the Great War Hungary lost over 600,000 men, and in its latter years the number of deaths exceeded the births. Emigration is considerable, although even before the War it was small in the area which is now Hungary compared with those parts which have been handed over to neighbouring states. The chief towns in 1920 were Budapest (928,996), too large for the existing state, but one of the most important railway centres in Europe; Szeged,

with 119,109 inhabitants, Debreczen (108,186), Kecskemet (73,109), Hodmezővásárhely (60,922), Miskolcz (56,982), Ujpest (56,489), and Kispeszt (51,064).

Agriculture.—This still remains the backbone of Hungary, which in 1921 was one of the chief wheat-growing regions in Europe, although much fertile land had been stripped from it. Much wine is produced, the most famous being Tokay. Sugar-beet and tobacco are also largely grown. In Hungary there were in 1922 717,485 horses, 1,827,832 cattle, 1,352,449 sheep, and 2,474,251 pigs, while the area in forest-land was 2,900,000 acres. Fisheries on the Danube and Theiss rivers and Lake Balaton are important.

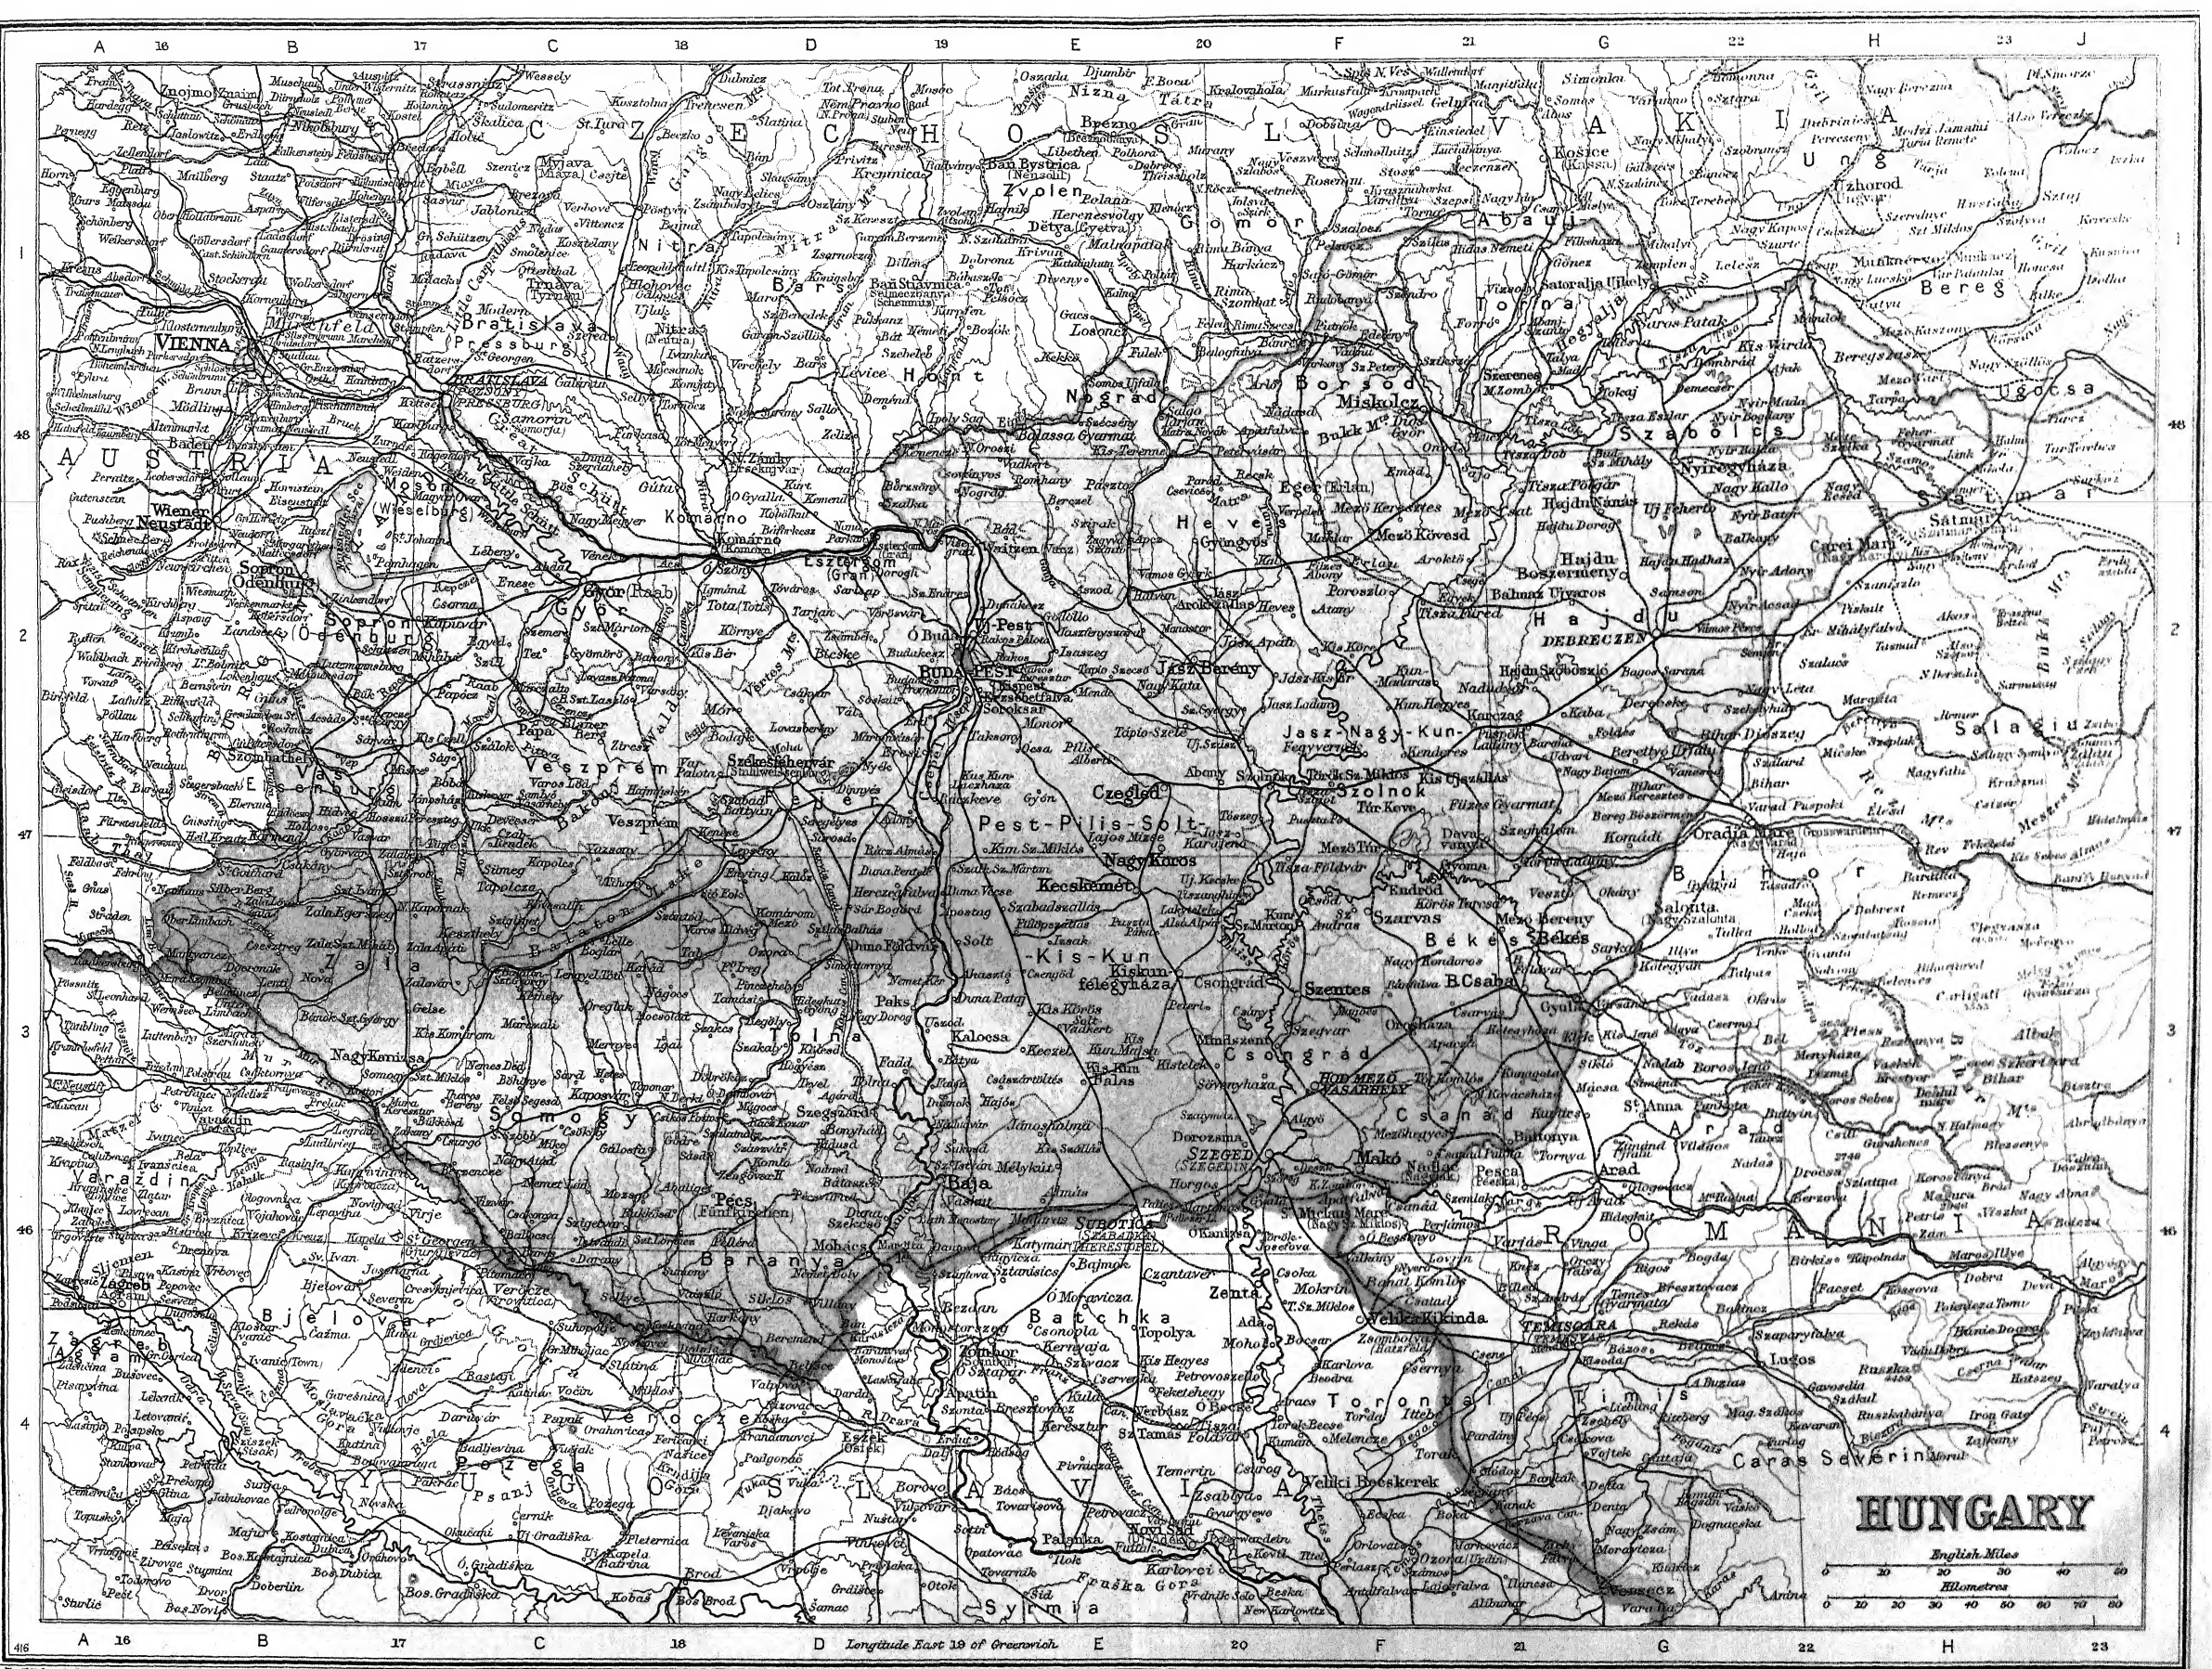

Industries.—These are to a great extent based on agriculture, and include milling, distilling, and the manufacture of sugar, hemp, and flax. There are also iron and steel works, and the coal production (the best quality of which is found in the district of Pécs) amounted in 1922 to 7,126,057 tons. Bituminous and brown coal are both found. With these exceptions Hungary has almost entirely lost her minerals, for which she was noted, and upon which she relied greatly.

Imports and Exports.—The imports of Hungary in 1922 included cotton tissues, wood, raw and worked (this is owing to the fact that only 4 per cent. of its coniferous trees remained to Hungary), coal, woollens, hides, cotton yarns, paper, raw metals, and machinery apparatus. The chief exports for the same year were flour, cattle, horses, electrical machinery, wine, meat, hardware, wool, feathers, and eggs.

Communications.—In 1922 there were 5327 miles of railway lines radiating from Budapest to all parts of the country. The Danube is a prominent means of communication, but this works adversely for Hungary, as it is under an international control. There are also the Kapos and Sárviz canals.

Defence.—According to the Treaty of Trianon between Hungary and the Allied Powers, Hungary is allowed to maintain an army of 35,000 of all ranks, to be supported on a voluntary basis. It has besides a gendarmerie of 12,000 and a police force of a like number, with 4500 customs guards. Hungary has no navy or air force, but maintains a force of patrol-boats and motor-launches on the Danube.

History.—But little is known of the history of the Hungarians previous to their appearance in Europe in 894. They are generally believed to be the descendants of the Scythians, and to have come from regions about the Caspian Sea. They first settled along the Middle Volga, but, having been pressed westwards, they in 889 crossed the Carpathian Mountains under Almos, and under the further leadership of his son Arpád they conquered the ancient Pannonia and Dacia of the Romans; and this, their new country, was in the year 1000 formed into a regular kingdom by Stephen. For his merits in Christianising his people Stephen was afterwards created a saint, and received from Pope Sylvester II. the title of 'apostolic king' and a crown, both of which have been worn by all the kings of Hungary to the present day. The Hungarians were at first an extremely warlike and even savage tribe; and, not content with subduing the various nationalities inhabiting the ancient Roman provinces, they made frequent expeditions into Germany and Italy, destroying the early results of Christian civilisation. All this, however, ceased on, and even before, the accession of Stephen, who turned his attention solely to the consolidation of Christianity and interior order and prosperity. He laid the foundation of many institutions surviving to the present day, such as the ecclesiastical organisation, the archbishoprics and bishoprics, the

municipal and county councils, and even the national council, which eventually developed into the Diet of the States. Within two decades after his death (1038) two attempts were made to overthrow Christianity, and to re-establish Paganism, but only with very slight and temporary success. Under Béla I. (1061-63), Ladislaus the Saint (1077-95), and Coloman the Learned (1095-1114), the country made very marked progress. The reign of Andrew II. is remarkable on account of the nobles having extorted from him in 1222 the 'Golden Bull,' or Hungarian Magna Charta, the privileges of which were in 1231 extended to the clergy and lower nobility. The 'Golden Bull' conferred many personal and material advantages on the nobles, and also contained a guarantee for the annual convocation of the diet; it conceded the right of armed resistance to any illegal acts of the king. During the reign of Béla IV. (1235-70) Hungary was devastated by a terrible Mongol invasion. To replace part of the population cruelly massacred by the Asiatic savages, Béla introduced German colonists; hence the German-speaking communities in Hungary to the present day. By the death of Andrew III. in 1301 the House of Árpád became extinct, and the throne of Hungary became an object of rivalry between various foreign potentates. After many vicissitudes, Hungary was fortunate enough to find a worthy king in the person of Charles Robert of Anjou (1308-42), who did much to place his adopted country on a level with more civilised western nations. His son, Louis the Great, made Hungary the most powerful nation of the period in central Europe. After the death of Ladislaus Posthumus (1457), Matthias Corvinus, the son of Hunyady, the great anti-Turkish hero and regent during that king's minority, was elected king. Under his reign Hungary attained to the pinnacle of fame, prosperity, civilisation, and power. He waged successful wars against Podiebrad of Bohemia, and got himself crowned king of Bohemia and Moravia. He also defeated the Turks at Kenyérmező, and reconquered the southern provinces held by them. In 1485 he even took Vienna and made it the capital of his country, which was at that time more extended than ever before or after. But Matthias was not only a great general; he was also a great legislator, a munificent patron of art and sciences, and a great judge. His impartiality and love for the people were so generally recognised that to the present day there lives in Hungary the proverb: 'King Matthias is dead; there is no more justice.' Matthias having died without legitimate heirs, the throne of Hungary again became the object of fierce struggles between various pretenders, and the country underwent in consequence a period of rapid decay. Under Vladislaus (1490-1516) Hungary was the scene of a sanguinary peasant insurrection, known as the Dózsa revolt, which was ultimately suppressed, and led to a system of abject serfdom. Louis II.'s reign was still more disastrous. The Turks, under Soliman the Great, took advantage of the enfeebled condition of the country, invaded it with a gigantic army, annihilated the Hungarian forces at Mohács, pillaged whole districts, including Buda where the world-famous Bibliotheca Corvina, and carried off some 30,000 Hungarians as slaves. Louis II. himself lost his life in or after the battle of Mohács, and the Hungarian throne became once more the prize of contention between two claimants. One was John Zápolya, Woiwode of Transylvania, whom one section of the nobles proclaimed king, the other was Ferdinand of Austria, brother-in-law of Louis II. Zápolya was supported by the Turks, Ferdinand by the majority of the Hungarian nobles. Eventually Zápolya

surrendered his claims to the whole kingdom, merely retaining Transylvania and the Transylvanian district of Hungary for life. Thus the Hapsburgs obtained at length a definite footing in Hungary, and the country entered on a period of endless suffering and humiliations.

The successors of Ferdinand—viz. Maximilian, Rudolph, Ferdinand II., Ferdinand III., and Leopold I.—when they were not engaged with the Turks, concentrated their energies on the suppression of Protestantism in Hungary. The Protestants won several victories over the Imperialists, as in 1604-6 under Stephen Bocskay, in 1620-21 under Bethlen Gabor, in 1644 under George Rákóczy, thus forcing the government to show more toleration towards the followers of the new religion; but the kings being under Jesuit influences, all treaties and promises were broken on the first opportunity. Especially ruinous was the long reign of Leopold I. (1657-1705), who, with the most merciless determination, used all means at his disposal, as he himself said, to 'impoverish, enslave, and recatholicise' Hungary. Some of his own highest office-holders, although themselves Catholics, so much resented his terrible treatment of the Protestants that they began a conspiracy for the separation of Hungary from the Hapsburg dominions; but the plot having been detected, the ringleaders were put to death. For many years the scaffolds were at work in suspected districts, and thousands of valiant families, mostly Protestants, were exterminated. A Protestant rising, under Count Emeric Tököly, and supported by Kara Mustapha, proved very successful in 1683, and very nearly led to the capture of Vienna and the utter destruction of Austria; but at the last moment John Sobieski, king of Poland, saved Vienna and the Hapsburgs. After the retreat of the Turks from Vienna they gradually lost their hold on Hungary.

Leopold died in 1705 amidst the anxieties entailed upon him by another Hungarian rising, led by a second Francis Rákóczy, which did not end before 1711. Leopold succeeded in causing the diet to declare the throne hereditary in the House of Hapsburg, and Charles VI. (1711-40) received their adhesion to the Pragmatic Sanction, securing the right of succession in the female line. Nevertheless, his daughter Maria Theresa's claim to the throne was called in question by several German rulers and by France, her dominions were invaded, and she saved them and herself only through the magnanimous self-sacrifice of the Hungarians. She was the first Hapsburg ruler who showed herself grateful to the Hungarians, and who proved herself to understand the duties of a sovereign. She made several concessions to the Protestants, improved the condition of the peasants, and established schools. Her son and successor, Joseph II. (1780-90), does not strictly figure among Hungarian kings, as he had never himself been crowned in Hungary, but carried on his reign in violation of the Hungarian constitution as an autocratic emperor. He was an enlightened reformer, but did not reckon with national feelings, class idiosyncrasies, interests, and prejudices; he attempted to make Hungary part of a vast pan-Germanic bureaucracy; and many of his measures fostered the discontent to such a degree that at his deathbed he saw himself compelled to recall all his illegal edicts, with the exception of one—viz. that enjoining religious toleration. Leopold II. at once convoked the diet (the first for twenty-five years), and confirmed the rights and independence of the nation. His conciliatory reign lasted only two years, and he was succeeded by Francis I. (1792-1835), whose ambition it was to follow the example of his least reputable predecessors. As

long as the Napoleonic wars lasted, and the Hungarians supported him with money and troops, he played at constitutionalism; but as soon as the Napoleonic dangers were passed he showed himself in his true character, discontinued the diets and levied troops and taxes at his pleasure till 1825, when he was driven by the general discontent and resistance to convoke the states.

This diet marked the beginning of the new era in Hungary. The nation commenced to awaken to the consciousness of its many wants, intellectual and material; the desire for reforms was fast ripening. The majority of the delegates to the next diet (1832) were already bearers of radical instructions. The desired reforms, however, were slow in coming, owing to the narrow-minded policy of Metternich and the whole court party. The diet of 1832 counted among its members such men as Count Louis Batthányi, Baron Nicholas Wesselényi, Baron Joseph Eötvös, Francis Deák, and Louis Kossuth. The more important reforms passed by this and the subsequent diets of 1839 and 1843 were those regarding the official use of the Hungarian language, the eligibility of non-nobles to public offices, and the equal rights of Christian denominations. Outside parliament there was no less activity than inside. Kossuth's *Pesti Hírlap* (the first Hungarian political daily paper), which in enthusiastic language taught the masses how to demand their rights, rapidly spread all over the country. Kossuth advocated the abolition of serfdom, the equality of all citizens, the liability of nobles to taxation, and freedom of the press. He was returned to the diet of 1847 as senior member for the county of Pest, and it was on his motion that the House resolved in March 1848 to send a deputation to Vienna to demand all these and various other reforms. Ferdinand V., a weak-minded man, who had reigned since 1835, yielded after some hesitation, and the first Hungarian responsible ministry entrusted with the task of carrying the said measures was appointed. Count Louis Batthányi was prime-minister, Deák minister of justice, and Kossuth minister of finance. But the court party were secretly determined to frustrate all these reforms, which openly they did not dare to oppose. They therefore incited the Croats and other non-Hungarian nationalities to rise against Hungarian supremacy. Accordingly Croatia, Slavonia, the Serbian Bánát, and eventually the Rumanians of Transylvania took up arms against Hungarian rule; and when the central government in Vienna was appealed to it issued highly-worded proclamations against the rebels, but gave very scant help to subdue them, whilst secretly it supplied them with arms, ammunition, and money. The Hungarian government, so treacherously abandoned, proceeded to obtain from parliament the vote of a levy of 200,000 men and 42 million florins of money, but to these measures, unanimously decreed by parliament, the crown withheld its assent. Later on, September 6, when a deputation of 120 members waited on Ferdinand to urge him to oppose the Croatian invasion, the court again gave an evasive reply. But a few days later, having received good news respecting the army, operating in Italy, the court threw aside the hypocritical mask hitherto worn, and declared open hostility to Hungary by ignoring the existing constitution and government, recalling the Palatine Archduke Stephen, and appointing Count Lamberg governor-general and royal commissioner for Hungary. Parliament declared these acts illegal, and Count Lamberg was murdered on his arrival by the enraged population of Budapest. The ministry now resigned, and a committee of national defence was appointed with Kossuth as

president. A comparatively numerous army was rapidly equipped and sent to meet Jellachich, who was marching towards Budapest at the head of the Croats. He was completely beaten at Velenze, and during an armistice of three days, which was granted him by the victorious Hungarians, he fled ignominiously towards Vienna. Notwithstanding this defeat he was appointed commander-in-chief of all the forces and alter-ego of the emperor-king in Hungary; and all the decrees and resolutions of the Hungarian parliament were declared illegal.

On December 2 Ferdinand was compelled by a family council to abdicate in favour of his nephew, Francis-Joseph, who was then eighteen years of age. In his name the war began to be carried on bitterly against Hungary, all the more as the diet declared the succession unconstitutional. Up to the middle of January next fortune seemed to favour the Austrian arms; the Hungarians, though they fought valiantly and obtained some victories, had to retreat before the overwhelming numbers of the enemy; the whole trans-Danubian district and the north and south were lost to them; they had only the vast plains of the Alföld and Transylvania, where Bem entirely subdued the rebellious nationalities. Meanwhile the Russians were also coming to the aid of the Austrians, so that the Hungarians had fair reason to despair of their own position. It was only the inactivity of Windischgrätz, the new Austrian generalissimo, that saved the Hungarians. His aimless stay at Budapest gave Kossuth time to perambulate the country, and by his stirring eloquence and boundless energy to create a splendid though irregular army, which, under the leadership of Görgei (q.v.) and others, won so many victories over the Austrians that soon the country was almost entirely free from the enemy. The many defeats of the Austrian regular forces by the Hungarian irregulars so exasperated the Vienna court that, on March 4, 1849, it promulgated a decree abolishing the Hungarian constitution; to which the Hungarian diet replied by the declaration of independence, and the dethronement of the Hapsburg dynasty on April 14. No final form of government was decided upon, but Kossuth was temporarily elected governor-president, and instead of the committee of national defence a new ministry was formed under the presidency of Bartholomew Szemere. Had Görgei not disregarded Kossuth's advice, had he forced his way to Vienna after so many victories, the whole war might have come to an end with glorious results for Hungary; but Görgei decided first to retake Buda, and thereby enabled the united Russian and Austrian armies to invade the country at various points. The Hungarians were defeated, and this decline of their fortunes was aggravated by the serious dissensions between Görgei and Kossuth, till the latter abdicated in favour of Görgei on August 11, 1849. Once in the possession of the chief political and military power, Görgei no longer thought of continuing the struggle, but immediately and unconditionally surrendered himself to the Russians. This act on his part was defended by him as one imposed by necessity and a saving of further bloodshed; but examined in the light of his former conduct and of the fact that he induced, by empty and futile promises for the safety of their persons and their troops, thirteen other generals to follow his example, it was long considered by the majority of his countrymen an act of unpardonable treason. Kossuth and several other military and political leaders fled to Turkey, whilst the others who remained behind and were captured were either sentenced to long terms of imprisonment or shot and hanged like mere criminals. Among the latter were Count Louis Batthányi and the thirteen generals who surrendered

with Görgei. Görgei himself was sent to Klagenfurt, and kept there on a small pension. Hungary was incorporated into and governed as an hereditary province of Austria, the governor being General Haynau, who wielded his official power with extraordinary harshness and cruelty. Political prisoners were tortured, women publicly flogged, properties and rights confiscated. With the exception of the abolition of serfdom all the acts of the diet of 1848 were annulled, and Hungary was governed by a host of foreign officials according to Austrian laws and institutions. The country displayed no active resistance, nevertheless all the efforts of this centralising and Germanising system so completely failed that by 1857 the Vienna government began to see its futility and to offer some concessions.

After the disastrous Italian war in 1859 the old Hungarian chancellery, as it existed previous to 1848, was re-established, but failed to satisfy the Hungarians, whose passive resistance threatened with a final breakdown the Austrian state machinery. At length in 1861 the diet was once more convoked; but, as it demanded the full restitution of the constitution of 1848, it was quickly dissolved. Gradually, however, better counsels prevailed at the court of Vienna. Parliament was again summoned in 1865, and the demands of the Hungarians, as formulated by Deák and his party, were complied with, and resulted in the agreement described in detail in the article AUSTRIA-HUNGARY. Francis-Joseph was crowned king of Hungary, June 7, 1867, and the country putting to good use the internal peace that followed the coronation, made rapid strides in the path of civilisation. It established an admirable system of elementary and higher education, built a magnificent net of railways (now largely in the hands of the state), improved its judicature, and greatly developed commerce and industry. The renewal of the decennial financial arrangement (1897-98) led to very strained relations between the two sections, the Hungarians declining to raise their contributions from 31.4 to 42 per cent. of the common expenditure. The various nationalities in Hungary never had the same share in public affairs as the Magyars; and the difficulties in harmonising Hungarian aspirations with imperial Austrian principles and methods became accentuated. In 1905 matters reached a crisis when the elections of January resulted in a severe defeat of the government party. It became impossible for the king to secure a ministry having the confidence of the house. The nationalist parties insisted on the sharp differentiation of the Hungarian from the Austrian army, on the use of Hungarian in words of command, and on an independent customs territory for Hungary. After a series of crises and coalitions, it was agreed in 1906 that there should be a new electoral system, on a basis of universal suffrage; and the two parliaments ratified a new treaty in 1907. The quarrel continued, however, although Hungary loyally supported Austria in the Great War, but she more and more insisted on an independent position at least as far as dealings with other countries were concerned, and her break from Austria at the end of the war was only a logical conclusion to their years of bickering. In November 1918 Hungary, in a desperate effort to please the allies, proclaimed herself a republic under Count Karolyi as president. This did not, however, last for long, as in March 1919 Béla Kun proclaimed a dictatorship of the proletariat, which was in fact Béla Kun and his myrmidons, who for five indescribable months wrecked the country. In August 1919 it was overthrown with ferocious barbarity. Shortly afterwards the Rumanians, to whom the chief share of the former Hungarian kingdom had been assigned, invaded Hungary and

occupied Budapest. Here they carried out vigorous and often brutal reprisals for the supposed ills Hungary had inflicted on them, and only left under definite orders from the chief allies, having, however, stripped the country bare. Then began another regime in Hungary, and Admiral Horthy was proclaimed regent until the country could have time free from outside pressure to choose its own king. The deposed King Karl made several very fatuous attempts to regain the crown of St Stephen, but he was prevented each time, and was at length sent to Madeira by the allies, where he died in 1922. Hungary, intensely monarchical at heart, is now enjoying a period of comparative prosperity, but the ruthless cutting down of her territories will remain a prolific cause whereby peace may breed war.

Language and Literature.—The Hungarians when they settled in their present land a thousand years ago brought their language with them, and this, although it has had since to borrow certain words from European languages to convey new ideas, has retained all its original features both as regards etymology and syntax. The Magyar or Hungarian language belongs to the Ugric branch of the Finno-Ugric group of Ural-Altaic languages. By reason of the perfect harmony between vowels and consonants, and the very distinct articulation and pronunciation essential to it, Hungarian is considered a very musical language, particularly adapted to poetry and rhetoric. Its grammar, moreover, is so strikingly different from that of the familiar European languages and so rich in original characteristics, that it offers a very interesting field to students of philology. It is acknowledged by them that it is well adapted to express ideas with the utmost clearness, owing to the distinctness and immense variety of endings and the originality and flexibility of its roots. Among its characteristics are that it has no genders, and *declination* and *conjugation* are effected by means of suffixes only; that the verbs possess objective and subjective forms (e.g. *látok*, 'I see'; *látom*, 'I see him or her or it'; *látsz*, 'thou seest'; *látod*, 'thou seest him or her or it,' &c.); that it invariably places the surname before the Christian name. It is also noteworthy that there are absolutely no dialects in the Hungarian language, and scarcely any difference of pronunciation in the various parts of the country.

From the date of the establishment of the Hungarian kingdom the use of the Hungarian language was so much restricted that a Hungarian literature can hardly be said to have existed before the close of the 18th century. The introduction of Christianity by Italian and German priests in the 11th century made Latin the official language and the medium of intercourse between the educated classes, and this remained so to a great, though gradually diminishing, extent up to the third and fourth decades of the 19th century. There was a slight reaction in favour of Hungarian after the Reformation, but the language was not taught in schools till the year 1790, and parliament did not discontinue Latin until 1825. The oldest Hungarian literary record extant is a funeral oration dating from the year 1171; there are also some religious songs and dramatic 'mysteries' from the 14th century. The first lay poet of real merit, Baron Valentine Balassa, lived in the second half of the 16th, the first great epic poet, Zrínyi, in the 17th century.

The revival of literature began to take place only towards the end of Maria Theresa's reign. Lyric poetry was cultivated by Anyos, Virág, Bacsnányi, and by Alexander Kisfaludy (1772-1844), Daniel Berzsenyi (1776-1836), Francis Kazinczy (1759-1831), and others, who not only added to the valuable stock of literature, but also enriched the language with new words and forms—Kazinczy excelling so much in this respect as to obtain the appellation of 'the recreator of the language.' Kölcsey, orator, essayist, and poet, and Charles Kisfaludy (1788-1830), the founder of Hungarian drama, were the chief literary figures at the beginning of the 19th century. Hungarian poetry, however, cannot be said to have possessed much originality at this period; it was reserved to such men as Petöfi (1823-49), Vörösmarty (1800-55), Arany (1817-82), and Tompa (1819-68) to regenerate Hungarian poetry on national lines. This end was attained towards the period of the war of independence, since which Hungary has produced a number of minor poets, such as Sárosy, Szász, Vajda, Kiss, Reviczky, Abrányi, and Rudnyánszky. In dramatic literature Charles Kisfaludy was followed by Szigligeti (1814-78), whose extreme fertility enriched it by many exceedingly successful plays. The classic tragedy *Bánk Bán* of Katona (1792-1830), and *The Human Tragedy*, a dramatic poem, by Madách (1823-64), on the lines of Goethe's *Faust*, but no less original, deserve especial mention. Amongst their successors there is only one great dramatist—Gregor Csiky. The Hungarian theatres rely mainly on products of foreign literature—French, English and German.

In prose literature Hungary has produced many standard works. The founder of the real Hungarian novel was Baron Nicholas Josika (1794-1865), whose historical and social novels on the model of Sir Walter Scott's works achieved great success and popularity. Baron Joseph Eötvös (1813-71) cultivated the sentimental novel, and the novel with a purpose. But among authors of fiction the highest rank is due to Maurus Jókai (q.v.), whose boundless imagination and profound humour have rendered him a favourite with readers in many countries beyond his own. Augustus Grégeros, Cyril Horváth, and Böhn in philosophy, Michael Horváth and Joseph Teleki in history, Count Andrassy and Paul Hunfalvy in travel, and Wenzel in jurisprudence, are names of honour in Hungary's book of letters and thought. The power both of acting and writing drama has been lavishly dealt out to the Hungarians, and amongst the most prominent dramatists may be mentioned Dóczy, Gregor Csiky, Edward Tóth, and Alexander Bródy, while from the younger school may be taken the names of Lingyel and Drégely.

Andreas Ady, whose lyrics attained power not so much from their own merit as from the fact that they were taken as the slogans of the revolutionary spirit, was steeped in a confused mysticism out of which his middle-class mind could not emerge with any order. The revolution of 1918 naturally brought forth a mass of half-digested work which is of interest as showing the trend of the times rather than as a serious literary effort. Sex emotionalism and a wild unrest which strives to become articulate predominate in the works of these writers. All literature in Hungary, however, is not at this level, and many serious efforts to analyse the times, logically and with reason, have appeared, and writers of history, philosophy, and jurisprudence have not been lacking to produce writings which can stand with the highest of Hungarian literary work. Beyond its own original productions Hungary also possesses admirable translations of all the masterpieces in the world's

literature. A collection of Shakespeare's plays is specially noteworthy, they having been translated by Hungary's greatest poets.

See Emil Reich, *Hungarian Literature, an Historical and Critical Survey* (1898); Polignac, *Notes sur la Littérature Hongroise* (1900); Kont, *Geschichte der ungarischen Literatur* (1906); F. Riedl, *Hungarian Literature* (1906); Ungarn, *Land und Volk* by various authors (1918).

Hunger. See APPETITE, DIGESTION.

Hungerford, a town of Berkshire, is situated on the river Kennet, 23 miles WSW. of Reading. It is a hunting centre, and a favourite resort of anglers, having been even in Evelyn's time 'a town famous for its troutes.' In the town-hall is preserved a horn gifted to the town by John of Gaunt in 1362.

Hünigen (Fr. *Huningue*), a town of Alsace, on the left bank of the Rhine, 2½ miles N. of Basel, is celebrated for its fish-breeding establishment (see PISCICULTURE). It was fortified by Vauban in 1679-81, but the works were finally destroyed in 1815, as were later works in 1921. Pop. 3600.

Hunnis, WILLIAM, a musician and poet who died in 1597. After plotting in 1555 to kill Queen Mary, he spent the years till the accession of Elizabeth in the Tower. By her he was appointed Master of the Children of the Chapel Royal and custodian of the gardens of Greenwich. He published *A Hye Full of Hunnye* and other volumes. See Life by Mrs Stopes (1911).

Huns (Lat. *Hunni*, Gr. *Ounnoi* and *Chounoi*), a nomad race of antiquity, whose remote ancestors were probably the Hsiung-nu, a people of Turkish stock, who formed a powerful state in Mongolia in the 2d century B.C. In 177 they conquered another large nomad race, the Yue-chi, akin to the Tibetans, and drove them westward and southward, they themselves following. But about the dawn of the Christian era their political power fell to pieces and the tribesmen were scattered. One section, however, seems to have fled westwards and to have settled in the neighbourhood of the river Ural and the Volga. At all events, some three centuries and a half later the people known to classic and medieval writers as Huns stepped upon the stage of history from that part of the world. About the year 372 they moved westwards again, under a leader called Balamir, and subdued first the Alani, who dwelt between the Volga and the Don, and then proceeded to attack the Ostrogoths, part of whom submitted somewhat tamely, whilst another part offered strenuous opposition, but were in the end compelled to submit likewise. This business completed, the Huns next invaded the territories of the Visigoths, and drove this people before them across the Danube, except one section, who, under Frithigern, sought permission of Valens, emperor of the East, to settle in his territories. The districts quitted by the Goths were occupied by the Huns. This, their first wave of invasion and conquest, seems then to have subsided; and, though it was followed by more than one smaller after-wave, it was not until about 430 that the second and greater wave began to gather head again in Rhuas or Rugulas. This chief acquired such power and influence that in 432 he imposed upon Theodosius II., emperor of Byzantium, an annual tribute of 350 pounds of gold. He was succeeded in 433 by his most illustrious nephew Attila (q.v.). His invasion of old Burgundian lands gave a powerful impetus to 'The Migration of the Peoples.' With Attila's death, however, in 453, the power of the Huns crumbled to pieces amid the intestine strifes of his sons and generals, and the attacks of their foes round about. After a most disastrous defeat inflicted upon them in Pannonia in 454 by the

combined armies of the Goths, Gepidæ, Suevi, Herulians, and others, the tribesmen of the Huns rapidly dispersed. Some settled in the Dobrudja, others in Dacia, whilst the main body seem to have returned to the land from whence they came—viz. the region about the river Ural. Some authorities identify these with the later Bulgarians, who about the end of the 5th century had risen into a powerful state on the Volga, and sent off conquering bands to the south-west, who finally settled in the modern Bulgaria.

The Huns are described as being of a dark complexion, deformed in appearance, of uncouth gesture and shrill voice. 'They were distinguished,' says Gibbon, 'from the rest of the human species by their broad shoulders, flat noses, and small black eyes deeply buried in the head; and, as they were almost destitute of beards, they never enjoyed either the manly graces of youth or the venerable aspect of age. A fabulous origin was assigned worthy of their form and manners—that the witches of Scythia, who for their foul and deadly practices had been driven from society, had united in the desert with infernal spirits, and that the Huns were the offspring of this execrable conjunction.' Like the Mongols, they were essentially a race of horsemen; they fought with javelins tipped with bone, with sabres, and with slings or lassoes. They ate herbs and half-raw meat, which they first used as saddles; and they clothed themselves with the skins of wild animals.

The White Huns or Ephthalites or Hephthalites are by some regarded as a branch of the Hiung-nu, though others make them the descendants of the ancient Royal Scythians, identifying them with the Barsileens, the allies of the Khazars. Whatever be their real origin, they were certainly established in ancient Bactria and the adjoining districts, between the Oxus and the Caspian, at a period contemporaneous with Attila's career. From the third decade of the 5th century onwards for about 120 years they were engaged in constant wars with their neighbours on the south, the Persians. In 484 the Ephthalites routed them in a fierce battle, in which Peroz, king of Persia, was amongst the slain. But their power seems to have been finally broken about 560 by the all-conquering Turks on their way to Asia Minor and Constantinople.

See De Guignes, *Histoire Générale des Huns* (vol. i. 1756); Neumann, *Die Völker des südlichen Russland* (2d ed. 1855); Thierry, *Histoire d'Attila* (4th ed. 1874); and Howorth, in *Jour. Anthropol. Inst.* (1872-74).

Hunstanton, a watering-place of Norfolk, on the Wash, 14 miles NE. of King's Lynn. It has a broad beach of firm sand, and good bathing and sea-fishing, a pier, and a splendid Decorated church (c. 1330). Hunstanton Hall, dating from the Tudor period, but greatly injured by fire in 1853, was the seat of Sir Roger L'Estrange. Pop. 4000.

Hunt, HENRY, surnamed 'Orator Hunt,' was born at Upavon, in Wiltshire, on 6th November 1773. He was a well-to-do farmer, but in 1800 his hot temper embroiled him with Lord Bruce, the commandant of the Wiltshire Yeomanry, which brought him six weeks' imprisonment. He came out of gaol a hot Radical, and spent the rest of his life travelling about the country addressing the people on behalf of the repeal of the Corn Laws and as an advocate of parliamentary reform. In 1819, on the occasion of the Peterloo massacre, he delivered a speech, which cost him three years' imprisonment. He died at Alresford, in Hampshire, on 13th February 1835.

Hunt, JAMES HENRY LEIGH, poet and essayist, was born at Southgate, near Edmonton, on 19th October 1784. His father, Isaac Hunt (1752-1809), a Barbadian, being driven by the Revolution from Philadelphia to London, gave up law for

the church, but lapsed into bankruptcy and Universalism. Leigh Hunt spent eight years at Christ's Hospital, and left at fifteen as first 'Deputy-Grecian,' debarred by a stammer from further promotion. He was a clerk first under one brother, an attorney, and next for four years in the War Office, writing meanwhile much dramatic criticism; in 1808 with another brother, a printer, he set up the *Examiner*; and in 1809 wedded Marianne Kent (1788-1857). The *Examiner's* tone was Radical, and, after several government prosecutions in 1813 for a libel on the Prince Regent (he had called him a 'corpulent Adonis of fifty'), Leigh Hunt was sentenced to a fine of £500 and to two years' imprisonment in Surrey gaol. There he 'scattered urbanity,' played battledore with his children, received hosts of visitors, and turned his cage into a 'bower of roses.' In November 1821 with his wife and seven children he sailed for Italy, but landed at Leghorn only on 1st July. He went on Shelley's invitation to help him and Byron to found the quarterly *Liberal*. Just a week later Shelley was drowned; Leigh Hunt and 'my noble friend' failed somehow to pull together; the *Liberal* died in its fourth number; and by 1825 the family was back at Highgate. Changes of residence, to Upper Cheyne Row, Chelsea, in 1833, to the 'old court suburb' of Kensington in 1840, and to Hammersmith in 1853—these are thenceforth the chief events in Leigh Hunt's life. It was one of ceaseless activity and as ceaseless embarrassment, for he 'never knew his multiplication table.' From 1844, however, Sir Percy Shelley allowed him £120 a year, and in 1847 he received a pension of £200. He died 28th August 1859.

The 'Cockney poets,' so the critics dubbed Keats and Leigh Hunt. That the two should ever thus have been bracketed may now seem strange, for Leigh Hunt's poetry now is little known. Its charm lies in a prettiness as of childhood; its wit and cleverness and wine-like sparkle have ever a smack of precocity. Narrative verse is his forte, his foible jauntiness. His translations are among the choicest of their kind; he transports the southern vintages to England, and their colour and flavour improve instead of losing by the voyage. As his poems, so his prose; his essays are always worth reading, but only after the *Essays of Elia*. Leigh Hunt's writings, indeed, are less memorable than his friendships—with Keats and Shelley, as also with Lamb, Byron, Moore, Coleridge, Dickens, Carlyle, and a whole galaxy of lesser luminaries. Our knowledge of them, and especially the first two, is largely derived from his.

In his excellent *List of the Writings of Hazlitt and Leigh Hunt* (1863) Alexander Ireland chronologically arranges with notes, &c., seventy-nine works by the latter, including *Juvenilia* (1801), *The Feast of the Poets* (1814), *The Story of Rimini* (1816), *Foliage* (1818), *Captain Sword and Captain Pen* (1835), and *The Palfrey* (1842); besides much in prose, as *Lord Byron and his Contemporaries* (1828), *Sir Ralph Esher* (1832), *Imagination and Fancy* (1844), *Wit and Humour* (1846), *Stories of the Italian Poets* (1846), *A Jar of Honey from Mount Hybla* (1848), and *The Old Court Suburb* (1855). See Leigh Hunt's *Poems* (ed. Milford 1922), his *Autobiography* (3 vols. 1850; revised ed. 1860) and *Correspondence* (2 vols. 1862). Forster's *Life of Dickens* (for the unkindly 'Harold Skimpole' episode), the *Cornhill* (i. 1860), Dowden in *Ward's English Poets* (iv. 1880); sketches by Cosmo Monkhouse (1893) and B. Johnson (1896); a study by B. Miller (1910); Edward Storer, *Leigh Hunt* (1911).

Hunt, THOMAS STERRY, an American chemist and geologist, born at Norwich, Connecticut, 5th September 1826, was assistant to the elder Siliman at Yale College, and from 1847 to 1872 chemist and mineralogist to the Canadian Geological Survey. He was also professor of Chemistry at Laval

University (1856-62) and at McGill University (1862-68); from 1872 to 1878 he held the chair of Geology in the Massachusetts Institute of Technology. In 1848-51 he contributed a series of papers on theoretical chemistry to the *American Journal of Science*; in organic chemistry his name is identified with a system essentially his own. His researches into the composition of rocks were of great importance. In 1859 he invented the green ink used for printing Greenbacks (q.v.). He was made an officer of the Legion of Honour in 1867, and became an F.R.S. (1859), and LL.D. of Cambridge (1881), and received many other distinctions. At his death, 12th February 1892, he had published over 200 papers and several larger works on chemistry and mineralogy.

Hunt, WILLIAM HENRY, English painter in water-colours, was born in London, March 28, 1790. He was one of the creators of the English school of water-colour painting, Ruskin pronouncing him to be among the greatest colourists of the school. His subjects are very simple—'Peaches and Grapes,' 'Old Pollard,' 'Basket of Plums,' 'Roses,' 'Wild Flowers,' 'Brown Study,' 'A Farmhouse Beauty,' 'Fast Asleep,' &c., but they are conceived in a finely poetical spirit, and present the perfection of finish. He died 10th February 1834.

Hunt, WILLIAM HOLMAN, painter, was born in London, 2d April 1827. In his early years he was engaged in business, but in 1845 he was admitted a student of the Royal Academy. In the following year he exhibited his first picture, 'Hark!' a child holding a watch to her ear; this was followed by scenes from Dickens and Scott, and by the more important 'Flight of Madeline and Porphyro,' from Keats's *Eve of St Agnes* (1848). At this period Hunt shared a studio with Dante Gabriel Rossetti, and the pair, along with Millais and a few other earnest young painters, inaugurated the 'Pre-Raphaelite Brotherhood,' of which the members aimed at detailed and uncompromising truth to nature in their rendering of visible things, and at a vivid and unconventional realisation in their treatment of imaginative subjects. In 1850 Hunt contributed to *The Germ*, the short-lived magazine of the brotherhood, two etched subjects illustrating Woolner's poem 'My beautiful Lady,' and at a later period he designed various woodcuts, in particular a remarkable series for the illustrated Tennyson of 1857. The first of the painter's works executed in the Pre-Raphaelite manner was 'Rienzi vowing to avenge the Death of his Brother' (1849), in which the principal figure was painted from Rossetti. It was followed by 'A Converted British Family sheltering a Christian Missionary from the Pursuit of the Druids' (1850); 'Valentine rescuing Sylvia from Proteus,' from the *Two Gentlemen of Verona* (1851); 'The Hired Shepherd' (1852); and 'Claudio and Isabella,' a tragic and impressive prison-scene from *Measure for Measure* (1853)—works very fresh and original in conception, and carried out with the most careful elaboration; while 'Our English Coasts,' known also as 'The Strayed Sheep' (1853), was a remarkable effort in landscape art, realising with exceptional power an effect of vivid sunlight, and combining in a wonderful manner detail and definition with a sense of distance and atmosphere. 'The Light of the World' (1852-54; a small replica of it, 1856; reproduced in life size, 1904) is one of the most impressive symbolical works of its century; it is now in the chapel of Keble College, Oxford. 'The Awakened Conscience' aimed to point a moral by means of a scene from modern life. On the completion of the last-named picture in the

beginning of 1854 Hunt started for Palestine, with the intention of studying Eastern life, and realising the incidents of the biblical history with the closest possible accuracy to local colouring and the surroundings amid which they occurred. The result of several prolonged visits to the East appeared in 'The Scapegoat' (1856); 'The Finding of Christ in the Temple' (1860), presented in 1896 to the Birmingham Art Gallery; 'The Shadow of Death' (1874), now in the Corporation Gallery, Manchester; and 'The Triumph of the Innocents' (1875-85), executed in two versions, which was the most serious labour of his life. 'Isabella and the Pot of Basil' was the result of a visit to Florence in 1867. Other pictures were 'The Choristers of Magdalen College, Oxford, singing the May Day Hymn'; 'The Holy Fire in the Church of the Sepulchre, Jerusalem'; and 'The Lady of Shalott.' In 1905 he received the Order of Merit. He died 7th September 1910. His paintings form a wonderful fulfilment of his youthful intentions, and are probably unique in English art.

He wrote autobiographical papers (*Contemp. Rev.* 1886), the article PRE-RAPHAELITISM in this work, and *Pre-Raphaelitism and the Pre-Raphaelite Brotherhood* (1905; revised from his notes, 1914). See Ruskin, *Modern Painters* (1886); P. H. Bates, *The Pre-Raphaelite Painters* (1890); and Lives by Williamson (1902) and Coleridge (1908).

Hunter, JOHN, physiologist and surgeon, was born at Long Calderwood, near East Kilbride, in Lanarkshire, 13th February 1728, and was the youngest of ten children. One of his sisters, Dorothea, was married to Dr James Baillie, professor of Divinity in the university of Glasgow, and was the mother of Matthew and Joanna Baillie (q.v.). His brother William's fame led John to apply for and obtain the situation of assistant in the dissecting-room. He studied surgery under Cheselden in 1749-50 at Chelsea Hospital, and subsequently under Pott. He entered St George's Hospital as surgeon's pupil in 1754, afterwards becoming house-surgeon and partner with his brother in the anatomical school. After ten years' hard work of this kind his health gave way, and in 1759 he entered the army as staff-surgeon, and served at Belleisle and in the Peninsula. Peace being proclaimed in 1763, he returned to London and, starting the practice of surgery, devoted much time and money to comparative anatomy. In 1767 he was elected a Fellow of the Royal Society, and in the following year was appointed surgeon to St George's Hospital, an appointment which enabled him to take pupils, of whom one of the earliest was Jenner. His practice at this time was increasing rapidly, and in 1776 he was appointed surgeon-extraordinary to the king. In 1785 he built his museum, with lecture-rooms, and in the same year he tried his famous operation for the cure of aneurysm—that of simply tying the artery at a distance from the tumour, and between it and the heart. In 1786 Hunter was appointed deputy-surgeon-general to the army; in 1787 he received the Copley Medal from the Royal Society. He was now universally acknowledged by all the younger surgeons as the head of his profession; but most of his contemporaries looked upon him as little better than an innovator and an enthusiast. He died 16th October 1793, and was buried in the church of St Martin-in-the-Fields, whence, thanks to Frank Buckland, his remains were translated in March 1859 to Westminster Abbey. Some idea of Hunter's diligence may be gathered from the fact that his museum contained at the time of his death 10,563 specimens and preparations illustrative of human and comparative anatomy, physiology, pathology, and natural history.

In addition to the numerous papers contributed to the *Transactions* of the Royal and other learned societies, he published the following independent works: *The Natural History of the Human Teeth* (1771-78); *A Treatise on the Venereal Disease* (1788); *Observations on Certain Parts of the Animal Economy* (1786); and *A Treatise on the Blood, Inflammation, and Gunshot Wounds* (1794). See Mather's *Two Great Scotsmen* (1894), and the *Life* by S. Paget (1897).

Hunter, WILLIAM, anatomist and obstetrician, an elder brother of John Hunter, was born at Long Calderwood, Lanarkshire, 23d May 1718. Originally educated for the church at Glasgow University, he studied medicine for one session (1740-41) at Edinburgh, and then proceeded to London, where he went through a long training in anatomy at St George's Hospital and elsewhere. In 1747 he was admitted a member of the Corporation of Surgeons, ultimately confining his practice to midwifery. In 1762 Hunter was consulted by Queen Charlotte, and two years later was appointed her physician-extraordinary. Elected a Fellow of the Royal Society, he in 1768 became professor of Anatomy to the Royal Academy. In 1770 he removed to Great Windmill Street, where he had built a house, in connection with which were an amphitheatre for lectures, a dissecting-room, and a museum which contained not only his anatomical preparations, but many objects of natural history and a cabinet of very rare medals and coins. Hunter and his brother John were for many years estranged, owing to a dispute as to the priority of certain discoveries; but the quarrel was made up while William was on his death-bed. He died 30th March 1783. His museum was bequeathed to his brother-in-law, Dr Baillie, and after him, with an endowment of £3000, to Glasgow University (q.v.). His most important work, *An Anatomical Description of the Human Gravid Uterus and its Contents*, did not appear in its complete form till after his death.

Hunter, SIR WILLIAM WILSON (1840-1900), statistician, was educated at the universities of Glasgow, Paris, and Bonn, and in 1862 entered the civil service of India. His first important office, that of superintendent of public instruction in Orissa (1866-69), gave him the opportunity to write *Annals of Rural Bengal* (1868) and *Comparative Dictionary of the Non-Aryan Languages of India and High Asia* (1868). Then, after filling the responsible offices of secretary to the government of Bengal and the supreme government of India, he was in 1871 appointed director-general of the statistical department of India. The Indian census of 1872 was his first work in his new position. His later books include the compendious *Imperial Gazetteer of India* (9 vols. 1881; 14 vols. 1886-88), *Orissa* (1872), *Life of Lord Mayo* (2d ed. 1876), *Statistical Account of Assam* (1880), *Famine Aspects of Bengal Districts* (1874), *Indian Mussulmans* (1871), *The Indian Empire* (new ed. 1895). In 1887 he was knighted. In 1890-96 he edited a series of *Lives of 'Rulers of India'*, to which he himself contributed *Dalhousie*. *The Old Missionary* (1895) is a touching story of Indian life.

Hunting. See FOXHUNTING, STAG, and the articles on the other animals hunted.

Huntingdon, SELINA, COUNTESS OF, was the second of three daughters and co-heiresses of Washington Shirley, second Earl Ferrers, and was born 24th August 1707. She married the Earl of Huntingdon in 1728, and became a widow in 1746. Adopting the principles of the Calvinistic Methodists, the founder of which sect was the famous George Whitefield, she made that eminent preacher one of her chaplains, and assumed a leadership among his followers, who came to be known as 'The Countess of Huntingdon's Connection.' Her labours at home increased with her years. For the education of

ministers she established and maintained a college at Trevecca, in Brecknockshire (removed in 1792 to Cheshunt, Herts); and built, or became possessed of, numerous chapels in different parts of the country, the principal one being at Bath. She died 17th June 1791. She left her chapels, then sixty-four in number, to the care of four persons. Most of them have become, in doctrine and practice, almost identical with the Congregational churches.

Huntingdon, the county town of Huntingdonshire, on the left bank of the Ouse, and the Ermine Street of the Romans, 59 miles N. of London. It became the seat of a royal castle in 917, and was incorporated in 1189. It has breweries, motor-body works, gramophone works, and nursery gardens. Here Oliver Cromwell was born (1599), and here the poet Cowper lived; the chronicler, Henry of Huntingdon (q.v.), was Archdeacon of Huntingdon. With the municipal borough of Godmanchester (pop. 2000), on the opposite bank, it formed a parliamentary borough, returning till 1867 two members, till 1885 one. Pop. 4000.

Huntingdonshire, an inland county of England, 30 miles long and 23 broad, is surrounded by Northampton, Cambridge, and Bedford shires. Area, 366 sq. m., almost the whole of which is arable or in pasture. Pop. (1801) 37,568; (1861) 64,250; (1921) 54,748. Huntingdonshire has no hill-ranges of any importance, and is watered chiefly by the Nene, which forms its northern boundary, and the Ouse; in the fen-district in the north-eastern part of the county, forming part of the Bedford Level (q.v.), there were formerly some large lakes or meres, notably Whittlesea, Ramsey, and Ugg; but these have been drained and reclaimed for cultivation. The soil consists principally of clay, with, in places, sand, gravel, and peat earth, the latter being almost wholly confined to the fen-district. Huntingdonshire comprises four hundreds and the municipal boroughs of Huntingdon, Godmanchester, and St Ives. It returns one member to parliament. A peculiarity in its civil government is that it is included under the same shrievalty with Cambridgeshire, the sheriff being annually chosen in rotation from the county of Cambridge, the Isle of Ely, and this county. Of its earlier inhabitants Huntingdonshire has numerous traces; two Roman roads traverse it; at Alwalton, Earith, and Chesterton are remains of camps, the construction of which is also ascribed to the Romans; and in many places Roman remains, as pottery, coins, &c., have been found. Among places of interest in the county those most worthy of mention are the ruins of Ramsey Abbey and Buckden Palace, the latter being formerly the residence of the bishops of Lincoln; Hinchinbrook House, anciently the seat of the Cromwell family; Kimbolton Castle, the seat of the Duke of Manchester, where Queen Catharine resided for some time; Denton (see COTTON, SIR ROBERT); Little Gidding (see FERRAR); and Brampton, where lived Samuel Pepys.

Hunting Leopard. See CHEETAH.

Huntington, a city of West Virginia, capital of Cabell county, on the Ohio, manufactures railway rolling stock. Founded in 1871, it had in 1900 a population of 11,923, and in 1920, 50,177.

Huntly, a burgh of Scotland, 41 miles NW. of Aberdeen. Near it is the ruin of Huntly Castle, which was the seat of the earls and marquises of Huntly (see GORDON). Huntly was the birthplace of Dr George Macdonald. Pop. 4000.

Huntsville, capital of Madison county, Alabama, in the valley of the Tennessee, 10 miles N. of the river, and 88 miles N. of Birmingham, has ice factories, foundries, and manufactures of cotton, cotton-seed oil, and flour; pop. 8000.

Hunyady Janos. John Corvinus Hunyady, governor of Hungary, one of the greatest war-captains of his age, was born towards the close of the 14th century. His origin is wrapped in mystery, the current legend being that he was a son of the Emperor Sigismund by a Wallachian lady. His life may be succinctly described as one unbroken crusade against the Turks. During the period 1437-56 he was the shield of Hungary, not only against external foes, but against the lawlessness of the nobles at home. The principal moments in his celebrated contest with the foes of Christendom are his expulsion of them from Transylvania in 1442; his brilliant campaign south of the Danube in 1443; his defeat in the bloody battle of Varna, 1444; and that at Kossovo in 1448; but his most glorious achievement was the storming of Belgrade (1456). Shortly afterwards Hunyady died of dysentery. During the minority of Ladislaus V. the great captain acted as governor of the kingdom (1445-53). Hunyady left two sons, Ladislaus and Matthias—the former of whom was beheaded at Buda on a charge of conspiracy; the latter succeeded to the crown of Hungary (q.v.).

Hunza-Nagar, the valley (containing the forts of Hunza and Nagar) of a river running into the Gilgit, at the extreme NW. corner of Kashmir. Together with Kanjut, the upper part of the same valley, it became British in 1891.

Huon Gulf. See NEW GUINEA.

Huon of Bordeaux, one of the Charlemagne cycle of romances. In its present form it is a prose version, dating from 1454, of a poem current about the end of the 12th century, and sometimes ascribed, without grounds, to the trouvère Huon de Ville-neuve. In the story, Huon, Duke of Guienne, one of the paladins of Charlemagne, in self-defence kills Charlot, son of Charlemagne, and is in consequence condemned to die, but his life is granted on a hard condition that he brings back from Bagdad some of the Saracen emir's teeth and beard after having kissed his daughter before his face. The dwarf Oberon gives him a magical cup and horn, one blast of which in the hour of peril brings him and 100,000 warriors to Huon's aid. Moreover, the princess Esclarmonde, like Medea, lightens his labours by falling in love with him, so that at last he is completely successful, and returns with her as his wife to clear himself before Charlemagne. The prose romance was printed at Paris in 1516; and Lord Berner's English translation, by Wynkyn de Worde, in 1534 (ed. Lee for E.E.T.S., 1882-87; simplified by Steele, 1896).

Hu-pei, one of the central provinces of China, watered by the Yangtse. See CHINA.

Hurd, RICHARD, English prelate and writer, named the 'Beauty of Holiness' on account of his comeliness and piety, was born at Congreve, in Staffordshire, January 13, 1720, and studied at Emmanuel College, Cambridge, of which he became a Fellow in 1742. In 1749 appeared his first notable production, *Commentary on Horace's Ars Poetica*. In connection with this work Gibbon wrote of the author, 'I know few writers more deserving of the great but prostituted name of eritic; but, like many critics, he is better qualified to instruct than to execute.' In 1750, on the recommendation of Warburton, of whom he was a life-long friend and admirer, and whose *Works* he edited in 1788, he was appointed one of the Whitehall preachers. He afterwards (1774) became Bishop of Lichfield and Coventry, but exchanged this see for Worcester in 1781; in 1783 he declined the archbishopric of Canterbury. He died May 28, 1808. His principal works are *Dissertations on Poetry, &c.* (1755-57); *Letters on Chivalry and Romance* (1762); *Dialogues on the Uses of Foreign*

Travel (1764); and *An Introduction to the Study of the Prophecies concerning the Christian Church* (1772). He was a pioneer of the romantics. See *Hurd's Works* (8 vols. 1811) and *Memoirs* by Kilvert (1860).

Hurdwâr. See HARDWÂR.

Hurdy-gurdy, a very old musical instrument of the stringed kind, something between a guitar and a lute in appearance. It has four or six cat-gut or wire strings attached to screw-pegs in the head; two of the strings stretch over the sounding-board to the tailpiece, and are sounded by a wooden wheel (under the cover *a* in the fig.) charged with rosin, which is turned by means of a handle with the player's right hand. The

Hurdy-gurdy.

strings are 'stopped' by an ingenious arrangement of keys, *b*, manipulated with the left hand. The remaining strings are stretched out of reach of the keys, and are tuned as drones. The instrument has a range of two octaves from the tenor (*G*) upwards. The rustic simplicity of its music made it at one time a great favourite among the peasantry of a great part of Europe (see Engel's *Musical Instruments*). The name hurdy-gurdy is also sometimes applied to the mechanical pianos familiar on the streets. The word was probably coined to express contempt of the instrument.

Hurlingham, at Fulham (q.v.) in Middlesex, on the Thames below the bridge, the headquarters of polo (till 1906 of pigeon-shooting).

Huron, the second in area of the five great lakes on the frontier between the United States and Canada, is connected at the north-west by St Mary's River with Lake Superior, and through the strait of Mackinaw with Lake Michigan. On the south it has an outlet by way of the St Clair River. It is bounded on the W. and SW. by Michigan, and elsewhere by Ontario. The lake is divided into two unequal parts by the Cabot's Head peninsula and Grand Manitoulin island, the parts to the north being called North Channel and Georgian Bay. Its extreme length is 263 miles; its greatest breadth, exclusive of Georgian Bay, 105 miles; average breadth, 70 miles. The area of the entire lake is 23,800 sq. m.; it is larger than Lake Michigan, although its basin is smaller. According to the perfected levels of the United States Lake Survey, its mean elevation is 581½ feet above sea-level; it is 20½ feet below Lake Superior, and 8½ feet above Lake Erie. Huron has a mean depth of about 250, and a maximum depth of 750 feet. There is an average difference between high and low water (due to winds and rain) of 1½ foot. Huron, like the other lakes, is subject to violent storms. It contains about three thousand islands, nearly all Canadian; some of them are of considerable size. The waters are very clear and pure, and abound in fish. There are numerous good harbours and roadsteads, most of them on the Canadian side; at Sand Beach, Michigan, there is a harbour of refuge. In olden geologic time the lake seems to have been both deeper and much more extensive.

Huronian, a subdivision of the Archæan rocks of Canada. See ARCHÆAN SYSTEM.

Hurons, a once powerful tribe of American Indians, belonging to the Huron-Iroquois family. In the early part of the 17th century the Hurons numbered about 30,000 persons, living in twenty-five villages within a small territory near Georgian Bay. By the end of the century the tribe had been nearly destroyed by the Iroquois, famine, and disease; and in 1693 the few survivors were removed by the French to Jenne Lorette, near Quebec. Here two or three hundred descendants still live; but very few are of pure blood, and all are Catholics, and have abandoned their own language for French.

Hurricane. See STORMS, and WIND.

Hursley, a village of Hampshire, 5 miles SW. of Winchester. John Keble, author of the *Christian Year*, was vicar here from 1835 till his death in 1866. In 1848, with the profits of that celebrated work, he restored the church, which is rich in modern stained glass. Keble himself lies buried in the churchyard, and in the chancel is the grave of Richard Cromwell.

Hurstmonceaux, a village of Sussex, 5 miles N. of Pevensey, with the extensive ivy-covered ruins of a fine castle, built of brick under Henry VI. by Sir Roger de Fienes, one of the heroes of Agincourt. It passed in 1727 into the hands of the Hares or Hare-Naylors. The then head of the house, Bishop Hare, took good care of the estate, but its resources were shamefully squandered by the two succeeding heirs, and about the close of the century the castle was unroofed and its valuable contents sold. The famous Broad Church leader, Archdeacon Hare (q.v.), was rector of the parish from 1832 till 1855, and lies buried in the churchyard. The church is Early English, with Perpendicular windows, and contains, among other ancient monuments, the fine canopied altar-tomb of the second Lord Dacre.

Hurstpierpoint, a market-town of Sussex, 8 miles N. by W. of Brighton. For St John's College (1849), a middle-class school, see LANCING.

Hus, JOHN. See HUSS.

Husband and Wife. The relation of husband and wife is constituted by Marriage (q.v.), and can be dissolved only by death or Divorce (q.v.).

In England the contract of marriage confers a new status on the contracting parties. The incidents and conditions of this status are fixed by law. It was an established principle of common law that husband and wife for some purposes became by the marriage a single person in the eye of the law; but this principle, while it still survives to some extent in connection with the criminal law, has by recent statutes been rendered practically inoperative in matters of civil right.

The husband is, in law, the head of the family. He has the right to choose the family home, and it is the duty of the wife to reside with him there. A woman, on her marriage, acquires the domicile of her husband, and, during the subsistence of the marriage, the domicile of the wife follows that of her husband. The only event during marriage which renders the wife capable of acquiring an independent domicile is a decree of judicial separation. An alien woman married to a British subject is deemed to be a British subject, and a female British subject becomes an alien by marrying an alien.

It is the duty of a husband to maintain his wife. If a husband deserts his wife or has so acted that she is justified in leaving him and living apart, and she is without means of support, there is vested in her, as an agent of necessity, authority to pledge his

credit for the purpose of providing necessities for herself and the children of the marriage who are lawfully in her custody, and that authority cannot be revoked by the husband. Under the Summary Jurisdiction (Married Women) Act, 1895, when a husband has been convicted of an aggravated assault upon his wife, or has deserted her, or, by his persistent cruelty or wilful neglect to provide reasonable maintenance for her or her infant children, has caused her to live separately from him, a court of summary jurisdiction may, on the application of the wife, order the husband to pay to the wife personally, or to any other person on her behalf, such weekly sum, not exceeding £2, as the court, having regard to the means of the husband and wife, considers reasonable. If a wife becomes chargeable to any union or parish, the guardians of the poor may recover from the husband the costs incurred by them in respect of the relief granted to or on account of the wife, and may apply to a court of summary jurisdiction for an order against him for payment of such sums, weekly or otherwise, towards her support as may be deemed reasonable. A husband who, having the means by work or otherwise to support his wife, wilfully refuses or neglects so to do so that she becomes chargeable to the parish is, under the Vagrancy Act, 1824, guilty of a criminal offence. The legal duty of a husband to maintain his wife ceases if she leaves him against his will and without reasonable cause, and, in any case, if she commits adultery. A wife is, as a general rule, under no legal obligation to support her husband. But where a wife has separate property and her husband becomes chargeable to the parish, a court of summary jurisdiction, on the application of the guardians of the poor, has the same power to make an order on her for his maintenance out of her separate property as it would have to make an order against the husband if the wife had become chargeable.

At common law a wife was incapable of acquiring or holding property, real or personal, independently of her husband. But the doctrine of the common law, with regard to married women's property, was, from about the end of the 17th century, greatly modified by the principles of equity; and now, by a series of statutes commencing about the middle of the 19th century, the whole law as to the property, contracts, and other transactions of married women has been transformed. The most important of these statutes is the Married Women's Property Act, 1882. By that statute a woman married on or after 1st January 1883 is entitled to hold as her separate property all real and personal estate which belonged to her at the time of her marriage, or comes to her in any manner after marriage, including wages, earnings, and money gained by her in any employment, trade, or occupation which she carries on separately from her husband. She may dispose, by will or otherwise, of all such property as if she were unmarried. Under the Married Women's Property Act, 1893, a will made by a married woman is now construed as extending to all property which she may leave at her death, and a will made by her during the subsistence of the marriage does not require re-execution or republication after the death of her husband. As regards contracts by married women, the Married Women's Property Act, 1893, provides that every contract entered into by a wife (otherwise than as agent) after 9th December 1893, shall bind all separate property which she may at the time of the contract or thereafter be possessed of or entitled to, and also be enforceable against all property which she may, after the dissolution of the marriage, be possessed of or entitled to. But it is expressly enacted that any

such contract is not enforceable against her separate property, which at the time of the contract or thereafter she is restrained from anticipating. The 'restraint on anticipation'—a clause invented by the Court of Chancery for the protection of property given or limited for the separate use of a married woman—has the effect of preventing the property so restrained from being made liable for debts contracted by the wife, even on the faith of her separate estate. The restraint continues effectual only during coverture. A restraint on anticipation may, in a settlement made since 1st January 1883, be effectually annexed to a life estate thereby given to her, though not in terms limited to her separate use, and only made separate estate by force of the Married Women's Property Act, 1882. The restraint was originally devised as a protection against the influence and control of the husband; but, as the law now stands, its chief importance lies in the protection it affords a married woman against obligations undertaken by her and the consequences of her own wrongful acts. The separate property of a married woman, in so far as it is not subject to any restraint on anticipation, is liable for all her debts and obligations, whether antenuptial or post-nuptial, including any damages and costs recovered against her. In the case of debts incurred by the wife before marriage, the husband is liable only to the extent of property belonging to her which he has become entitled to from or through her. A married woman is now capable of suing and being sued as if she were a *feme sole*, and her husband need not be joined with her as plaintiff or defendant or be made a party to any legal proceeding brought by or taken against her. She has the same civil remedies against her husband for the protection and security of her separate property as if it belonged to her as a *feme sole*; but no husband or wife can sue the other for a tort. Each of the spouses has an insurable interest in the life of the other. Under the older law a married woman (unless she were carrying on a separate trade according to the custom of the city of London) was not liable to be made bankrupt even though she had a separate estate. The Bankruptcy Act, 1914 (4 and 5 Geo. 5, chap. 59), however, while maintaining the general exemption of married women, enacts (sect. 125) that every married woman who carries on a trade or business, whether separately from her husband or not, is subject to the bankruptcy laws as if she were a *feme sole*.

A husband, by virtue of the marriage alone, is not liable on a contract entered into by his wife during the marriage. The question whether the husband incurs liability under such a contract depends on whether the wife contracted on her own behalf or on behalf of, and as agent for, her husband. This is for the most part a question of fact, but certain presumptions of fact and of law are operative. Thus, where a husband and wife are living together, the wife is presumed to have her husband's authority to pledge his credit for necessities suitable to their style of living. This presumed authority extends only to things which are reasonably necessary and suitable to the style in which the husband chooses to live, and which fall fairly within the domestic department which is ordinarily confided to the management of the wife. The presumption of authority may be rebutted by proof that the wife was sufficiently provided with necessary articles or had an adequate allowance for the purchase of such articles, or by proof that the husband had prohibited his wife from pledging his credit. But where the husband has so acted as to induce a person contracting with his wife to believe that she had authority to pledge his credit, he may, in a question with that person, be barred from denying

that she had such authority. Thus when a tradesman has previously supplied goods to the wife upon the credit of her husband and the husband has paid him without demur in respect of such dealings, the tradesman has a right to assume, in the absence of notice to the contrary, that the wife continues to have authority to contract on her husband's behalf; and in such a case a general advertisement that the husband has revoked his wife's authority to pledge his credit will not suffice to prevent him from incurring liability on contracts subsequently made by her with the tradesman within the scope of her ostensible authority, unless it is shown that the advertisement had come to the actual knowledge of the tradesman.

In civil cases the rule at common law was that husbands and wives were not competent to give evidence for or against each other. But the Evidence Amendment Act, 1853, rendered husbands and wives competent and compellable, in all civil cases, to give evidence on behalf of any or either of the parties to the suit. This enactment did not apply in proceedings instituted in consequence of adultery. By the Evidence Amendment Act, 1869, however, husbands and wives of parties to proceedings instituted in consequence of adultery were made competent witnesses. The Act of 1869—as is now settled by the decision of the House of Lords in *Russell v. Russell*, 1924, A.C. 687—has not affected the rule of law that neither a husband nor a wife is permitted to give evidence of non-intercourse after marriage to bastardize a child born in wedlock. In criminal cases the common law rule was that husbands and wives were not competent to give evidence for or against each other, except where the husband was charged with some act of personal violence upon his wife or the wife with some act of personal violence upon her husband. From time to time statutory exceptions were made to this rule, and now, by the Criminal Evidence Act, 1898, in all ordinary crimes the wife or husband of the party charged is competent to give evidence, but only for the defence and only on the application of the person charged. There are, however, certain exceptional cases—e.g. where the crime charged is bigamy, incest, or one of certain specified sexual offences, or consists in an act of personal violence upon the husband or wife or involves injury to children—in which the husband or wife of the person charged is a competent witness for either the defence or the prosecution, irrespectively of the consent of the party charged. In no case, civil or criminal, can a husband or wife be compelled to disclose any communication made to him or her by the other during the marriage.

As the law stood prior to 1st January 1926, if a wife died intestate survived by her husband the whole of her separate personal estate passed to him as her administrator for his own behoof. The law also permitted the husband on the death of the wife to take, on certain conditions, a life interest—known as the curtesy—in lands belonging to the wife of which during the marriage she was seized for an estate of inheritance. When the wife's estate was held as her separate property, the husband's curtesy might be defeated by a deed or will disposing of the estate. If a husband died intestate leaving a widow and descendants, the widow was entitled to one-third of his free personal estate, and if he left a widow and no issue, the widow was entitled to one-half. Moreover, under the Intestates' Estates Act, 1890, where a man died intestate leaving a widow but no issue, the whole of his real and personal estate, if not exceeding £500 in net value at the date of his death, belonged to the widow absolutely; and, if his estate exceeded £500 in net value, the widow was entitled to £500 thereof absolutely in addition to the interest and share in

the residue of the estate, real and personal, which she would have had under the previous existing law. The surviving wife had also a right to 'dower,' consisting at common law of an estate for her life in one-third part of the freehold lands and tenements of which her husband was solely seised for an estate of inheritance during the marriage. The Dower Act, 1833, conferred on the husband complete control over dower, so that a woman married after the date of that act could claim dower only where her husband died intestate and there was no declaration by deed barring dower. The Law of Property Act, 1922 (12 & 13 Geo. 5, chap. 16), coming into force on 1st January 1926, abolishes curtesy and dower, repeals the Statutes of Distribution and the Intestates' Estates Act, 1890, and substitutes an entirely new set of rules of succession on intestacy. On the death of a person intestate after 1st January 1926 the personal representative is to hold all real and personal estate upon trust for sale. If the intestate leaves a husband or wife, the surviving husband or wife takes: (a) All the personal chattels absolutely—these being defined in sect. 154 (1) (iv.) of the act, as meaning furniture, plate, pictures, carriages, household and garden effects, except those acquired for business purposes and except money and securities for money; (b) £1000 free of death duties and costs, with interest thereon at the rate of 5 per cent. from the date of the death; (c) the income of half the residue for life if the deceased leaves issue; (d) the income of the whole residue for life if the deceased leaves no issue. There is a provision enabling the life interest of the surviving husband or wife to be redeemed by a capital payment so as to free the residue for distribution. Where the predeceasing spouse has left a will effectually disposing of part of his or her estate, the above-mentioned rules apply to the part not disposed of.

In Scotland a husband is bound to aliment his wife while she is living with him, and also while she is living apart if he has deserted her or has been guilty of cruelty or adultery, or if she is living apart with his consent. His wilful neglect to supply her with necessary food and clothing, whereby she becomes chargeable to a parish, renders him liable to imprisonment. In the event of a husband being unable to maintain himself, his wife, if she has separate estate or a separate income more than reasonably sufficient for her own maintenance, is bound, out of such separate estate or income, to provide her husband with such maintenance as he would in similar circumstances be bound to provide for her. At common law the husband's interest in his wife's property comprised two distinct rights, known as the *jus mariti* and the *jus administrationis*. The *jus mariti* conferred on the husband an absolute right of ownership in all the wife's moveable property, whether vested in her at the date of the marriage, or acquired by her during the subsistence of the marriage. The wife's heritable property did not fall under the *jus mariti*. She remained owner of the *corpus* of such property, but the income of it fell to the husband in virtue of the *jus mariti*. The *jus administrationis* was the right of the husband, as his wife's curator or administrator-in-law, to control her management of her property which had not passed to him *jure mariti*. In virtue of this right of administration, obligations undertaken by the wife, or deeds granted by her, though relating to property of which she remained owner, had to be sanctioned by her husband's concurrence. But now, by a series of statutes, culminating in the Married Women's Property Act, 1920, the law as to the property of married women has been fundamentally altered. *Jus mariti* is now, apart from contract, applicable only where the marriage was contracted before 18th July 1881 and the wife had

acquired moveable estate prior to that date. In all other cases the moveable estate of the wife, whether acquired before or during the marriage, is vested in her exclusive of *jus mariti*. Nor is a wife's property, heritable or moveable, any longer subject to the right of administration of her husband. In dealing with her estate she has the same powers of disposal as if she were unmarried. She is capable of entering into contracts and incurring obligations, and of suing and being sued, as if she were not married, and her husband is not liable in respect of any contract she may enter into, or obligation she may incur, on her own behalf. The liability of the husband for contracts entered into by the wife on his behalf, and as his agent, is determined in Scotland on principles substantially identical with those recognised in England. The wife, as *præposita rebus domesticis*, is presumed to be authorised by her husband, the master of the house, to order on his behalf such articles as fairly fall within the domestic department. It was a rule of Scots common law—inherited from Roman law—that donations by a husband to his wife or by a wife to her husband were liable to revocation at any time during the life of the donor. This rule is now abolished by the Married Women's Property Act, 1920, which enacts (sect. 5) that donations *inter virum et uxorem* shall be irrevocable by the donors. The statute, however, contains a proviso that any donation completed within a year and day before the sequestration of the estates of the donor under the Bankruptcy Act, 1913, or any amending statute, shall be revocable at the instance of the creditors of such donor. The legislation rendering it competent in Scottish courts for husbands and wives to give evidence in civil and criminal cases for or against each other has followed, generally speaking, the same lines as in England. In Scotland, on the death of one of the spouses, whether testate or intestate, the surviving spouse has certain legal rights in the estate, heritable and moveable, of the predeceasing spouse, unless these rights have been discharged or satisfied. The wife, on the death of her husband, is entitled *ex lege* to (a) *terce*, a right of liferent in one-third of the heritable estate of her deceased husband, and (b) *jus relicte*, a right to one-half, or, if the husband has left children, to one-third, of his moveable estate. The corresponding rights of the husband arising *ex lege* on the death of his wife are (a) *courtesy*, a right, on certain conditions, to a liferent of all his wife's heritable, and (b) *jus relicti*, a right to one-half, or, if the wife has left children, to one-third, of her separate moveable estate. The rights of the widow in the estate of her husband, when he has died intestate, have been considerably extended by the Intestate Husband's Estate (Scotland) Act, 1911. That act, which was amended by a subsequent act passed in 1919, conferred upon the widows of intestates in Scotland rights substantially similar to those which had been conferred upon the widows of intestates in England by the Intestates' Estates Act, 1890 (*vide supra*).

In the United States the law of husband and wife is based upon the common law of England. There, however, as in England, statutory enactments in recent years have removed the common law disabilities of married women in relation to property, contracts, and other matters of civil right. The statutes conferring on married women control of their separate property and regulating their contractual and other powers vary greatly in the several states, thereby producing considerable confusion. In some states married women have absolute control over their property, as if unmarried. The statutes of other states have not gone further than to incorporate the principles recognised in equity in respect to a married woman's separate

estate. In the absence of proof to the contrary, it is presumed by the courts of one state that the common law prevails in another state as to the rights of married persons. In Canada the rules as to the property and powers of married women differ in the various provinces.

Husch, or **Husi**, a town of Rumania, near the Pruth, 38 miles SSE. from Jassy, with an ancient cathedral. It has a trade in live-stock and wine. It was founded by fugitive Hussites in the 15th century. Here was signed in 1711 the treaty between the Russians and Turks by which Peter the Great rescued his army. Pop. 15,000.

Huseyn Ali, **MIRZA**, otherwise **BAHA ULLAH**. See **BABI**.

Huskisson, **WILLIAM**, statesman and financier, was born at Birtmorton Court, in Worcestershire, 11th March 1770, and in 1783 was sent to Paris to study medicine. He was present at the storming of the Bastille, and as a member of the Club of 1789 attracted attention by a speech on the assignats. Returning to England, he was appointed in 1795 under-secretary in the Colonial Department. Next year he entered parliament for Morpeth as a supporter of Pitt. Being returned for Liskeard in 1804, he was appointed secretary of the Treasury; and he held the same office under the Duke of Portland (1807-9). In 1814 he became chief Commissioner of the Woods and Forests; in 1823 President of the Board of Trade, and treasurer of the navy; and in 1827 Secretary of State for the Colonies. But he resigned office finally in the following year. Through his exertions the old restrictions on the trade of the colonies with foreign countries were removed. He also obtained the removal or reduction of many import duties, considerable relaxation of the navigation laws, and is allowed to have been an active pioneer of free trade. He received fatal injuries at the opening of the Liverpool and Manchester Railway, 15th September 1830, and died the same evening. A collection of his speeches, with a Life prefixed, was published in 3 vols. in 1831.

Huss, or more properly **Hus**, **JOHN**, Bohemian reformer and martyr, was born in (probably) 1369, the son of a Bohemian peasant, at Husinec (of which Hus is a contraction), NW. of Budweis. Two years after taking (1396) his master's degree at the university of Prague he began to lecture there on theological subjects. In 1402 he was appointed rector of the university, and began to preach at the Bethlehem chapel in the city of Prague. It was not until the year 1408 that he came into conflict with the Roman Catholic Church. In that year certain of his pulpit utterances against clerical abuses were laid hold upon by the clergy of the diocese and city of Prague, and made the ground of a formal complaint against him to the archbishop, Sbynko. In consequence of this Huss was forbidden to exercise priestly functions within the diocese. Early in the following year the element of political feeling was infused into the quarrel, all the strong interests of the awakening national consciousness ranging themselves in support of the reformer, who by his preaching had completely won the hearts of the common people. Although Huss was again elected rector of the university in October 1409, the archbishop commissioned an inquisitor to investigate the charges of heretical teaching which had been alleged against him. And it was undoubtedly in connection with this proceeding that in December the pope (Alexander V.) promulgated a bull in condemnation of Wyclif's teaching, and ordered all his writings to be publicly burned, and at the same time forbade preaching in any except collegiate, parish, and monastery churches. This, however,

not being sufficient to prevent Huss from continuing his preaching, he was in the following July excommunicated by the Archbishop of Prague. Popular riots followed in the city, and Huss, backed by the people, still maintained his position; nor did he yield one jot even after the entire city was laid under a papal interdict in 1411. But by the last month of the following year matters had greatly changed, in consequence of Huss having spoken out yet more boldly against the church; hence some of his more influential supporters, including the university, had fallen away from him, so that he was constrained to yield to the desire of the king of Bohemia, Wenceslaus, that he should absent himself from Prague. He found refuge at the castles of certain of his supporters, for nearly the whole body of the nobles were with him. This enforced leisure he employed chiefly in the composition of his principal work, *De Ecclesia*. This book, together with many of Huss's minor writings, contains numerous passages taken almost verbatim from Wyclif's works; and the authorities of the Roman Catholic Church must have looked upon Huss as the expounder and propagator of Wyclif's views. About this time a general council was summoned to meet at Constance, and Huss was called upon to present himself before it, in order to have his case adjudicated upon. Provided with a 'safe conduct' from the Emperor Sigismund, he arrived at Constance on 3d November 1414. Three weeks later, in violation of his safe-conduct, he was seized and thrown into prison. No precise charge had been lodged against him; but he had resumed preaching after his arrival in Constance. An ill augury for Huss was the condemnation of Wyclif's writings by the council in May 1415. His own trial began on 5th June following; but he was not permitted to speak freely in his own defence, nor allowed to have a defender to speak in his behalf. Called upon to recant unconditionally, to make full submission to the council, and to pledge himself not to preach or teach the doctrines that were put in accusation against him, Huss categorically refused, and was forthwith led to the stake, and burned to ashes, on 6th July.

HUSSITES.—The news of the imprisonment and death of John Huss roused popular feeling in Bohemia to the highest pitch of wrath and indignation. Whilst the masses gave way to rioting and murdered Roman Catholic ecclesiastics, 452 nobles, in a diet which had been hastily summoned at Prague in September 1415, solemnly attested their confidence in Huss, and their admiration of his personal character, and three days later formed themselves into a league for the maintenance of liberty of preaching in Bohemia, and for upholding their belief in the Word of God as the ultimate lawgiver of the church. For this they were excommunicated by the council. Both parties now prepared for war. Yet it soon became apparent that the Hussites were not all of one mind: for, as in all great popular movements of this kind, there was an extreme party who were desirous of carrying things to the greatest lengths. The more moderate section formulated their demands in four articles, preaching of the gospel in the Bohemian language, the right of the laity to receive the communion in both kinds, reform of clerical abuses, and the prohibition of the clergy to hold secular property and exercise secular jurisdiction; these were called *Praguers*, but more frequently *Calixtines* (*calix* = a chalice) or *Utraquists* (from their claiming communion *sub utraque specie*). The extreme party, headed by Ziska (q.v.), and called *Taborites*, from their headquarters being at Mount Tabor, some 24 miles NE. of Pisek, went beyond the Utraquists in their condemnation of purgatory, the worship of saints, of images, and of relics, and the

practice of penance, and in their assertion of the right of the laity, even of women, to preach, and that in any building they pleased. At this period too King Wenceslaus died, and the throne of Bohemia was claimed by his brother, the Emperor Sigismund. Nevertheless, both parties united in offering a stubborn resistance to the emperor, and his forces were defeated at Ziskaberg in 1420, at Deutsch-Brod in 1422, at Aussig in 1426, and at Taus in 1431. Under the two brothers Procopius the Hussites invaded Silesia, Saxony, and Franconia; they were said to have taken and destroyed more than 100 towns and 1500 villages; according to a doubtful legend, Naumburg was saved by the intercession of the school-children. After the battle of Taus negotiations were begun, which ended, two years later, in the Calixtines securing their ends by the 'Compactata of Prague,' which was signed by the delegate of the Council of Basel on 30th November. This pacification the Taborites refused to accept, and in the contest that then ensued between them and the Calixtines, they were worsted at Lipan near Kolin and at Hrib near Bohmisch-Brod in 1434, and from that time rapidly disappear from history. Two years later the Emperor Sigismund, after ratifying the 'Compactata' with his signature, was accepted by the Bohemians as their king. The Utraquists finally became merged in the Moravian Brethren (q.v.).

See *Documenta Johannis Hus vitam, doctrinam, causam illustrantia* (ed. by Palacky, 1869), and monographs by Becker (1858), Krummel (1863), Berger (1872), Wratislaw (in English, 1882), and Loserth (1884; Eng. trans. 1884); Denis, *Huss et la Guerre des Hussites* (1878); Palacky, *Urkundliche Beiträge zur Geschichte des Hussitenkriegs* (1872-73); Krummel, *Geschichte der Böhmisches Reformations* (1866); Bezold, *Zur Geschichte des Hussitentums* (1874); Lechler, *Johannes Huss* (1890); Huss's own *Opera Omnia*, at last critically edited (1903 et seq.); Count Lützow's *Bohemia* (1896), his *Life and Times of Hus* (1909), and his *Hussite Wars: 1410-36* (1914); Workman and Pope, *The Letters of John Hus* (1904); Schaff, *John Hus* (1915); the articles CZECHO-SLOVAKIA (*Literature*), ZISKA, FODIEBRAD, CONSTANCE, WYCLIFFE, &c.

Hussar, a light-cavalry trooper, wearing in full dress a tunic and busby. The 10th and 18th Light Dragoons were changed in 1806-7 to Hussars, the earliest in the British army. Owing to retrenchment there are now nine Hussar regiments instead of twelve. The extra three have been amalgamated, 13th with the 18th, 14th with the 20th, and the 15th with the 19th (see CAVALRY). The name is not a Hungarian *huszár*, indicating that they were raised one out of every twenty inhabitants; nor Slavonic for 'Gooseherd'; but a Hungarian adaption through old Serbian of Italian *corsaro*, free-booter.

Hussein. See SHĪTES; also HEJAZ.

Husum, an old town in the Prussian province of Sleswick-Holstein, 23 miles W. of Sleswig by rail and 2½ from the North Sea; pop. 10,000.

Hutcheson, FRANCIS, a distinguished philosopher of the 18th century, was the son of a Presbyterian minister in the north of Ireland, where he was born in 1694. He studied for the church at the university of Glasgow, but shortly after the completion of his theological course he was induced to open a private academy in the city of Dublin, which proved highly successful. In 1720 he published his *Inquiry into the Original of our Ideas of Beauty and Virtue*, &c., which was the means of introducing him to the notice of many influential personages, such as Lord Granville, then lord-lieutenant of Ireland, Archbishop King, Primate Boulter, and others. This work was followed in 1728 by his *Essay on the Nature and Conduct of the Passions*; and in the year after he was

appointed professor of Moral Philosophy in the university of Glasgow. Here he died in 1747. In his lifetime he published various minor books, including a small treatise on *Logic*; but his largest work, *A System of Moral Philosophy*, was published at Glasgow in 1755 by his son, Francis Hutcheson, M.D., with a Life by Dr Leechman. As a metaphysician Hutcheson may in some respects be considered a pioneer of the so-called 'Scottish school' and of the common-sense philosophy, although he is largely influenced by Locke. From the delivery of Hutcheson's lectures, according to Dugald Stewart, may be dated the metaphysical philosophy of Scotland. But it is as a moral philosopher, rather than as a metaphysician, that Hutcheson was conspicuous. His system is to a large extent that of Shaftesbury, but it is more complete, coherent, and clearly illustrated. Hutcheson is a strong opponent of the doctrine that benevolence has a selfish origin; he is practically a utilitarian; and the faculty by which moral distinctions are recognised Hutcheson (after Shaftesbury) terms a *moral sense*. See ETHICS; Fowler, *Shaftesbury and Hutcheson* (1882); and W. R. Scott, *Francis Hutcheson* (1900).

Hutchinson, ANNE, a religious enthusiast, was the daughter of a Lincolnshire clergyman called Marbury. Born in 1590, she married a Mr Hutchinson, and in 1634 they emigrated from Lincolnshire, England, to Boston, Massachusetts. She held various theological heresies; amongst others, that the person of the Holy Ghost dwells in justified persons. She held meetings, lectured, and denounced the Massachusetts clergy as being with few exceptions 'under the covenant of works, not of grace.' Her followers were charged with Antinomianism (q.v.). Great controversies arose, and a synod was called, in which her teachings were condemned; and being tried for heresy and sedition, she was banished from the colony. She and her friends acquired territory from the Narragansett Indians of Rhode Island, where they set up a community on the highly commendable principle that no one was to be 'accounted a delinquent for doctrine.' After the death of her husband (who shared her opinions) she removed to a new settlement in what is now New York state, where, in 1643, she and her whole family of fifteen persons were taken prisoners by the Indians, and all but one daughter barbarously murdered.

Hutchinson, JOHN, an English theological writer, born in 1674 at Spennithorne, in Yorkshire. He was for some time steward of the household of the Duke of Somerset, and left his service to devote himself to his religious studies, the duke procuring for him a sinecure appointment of £200 a year from government. In 1724 he published the first part of a work called *Moses' Principia*, in which he defended what he regarded as the Mosaic cosmogony, and assailed Newton's theory of gravitation. He continued to publish a succession of works till his death, which took place on 28th August 1737. His religious system is best exhibited in his *Thoughts concerning Religion*. The leading principle of it is that the Holy Scriptures contain the elements not only of true religion, but of all rational philosophy, which, however, was to be derived only from the original Hebrew; and it, for that purpose, was subjected to strange critical or rather fanciful processes. His followers were called HUTCHINSONIANS, and among them were persons of considerable learning and celebrity.

Hutchinson, COLONEL JOHN, the type of the Puritan gentleman, was the son of Sir Thomas Hutchinson, and was born at Nottingham about September 1615. He studied at Cambridge, and next for a short time at Lincoln's Inn, and married in 1638 Lucy, daughter of Sir Allen Apsley. He now

retired to Owthorpe, and here his meditations on the troubled theology and politics of the time led him at last to side with the parliament rather than the king. He became governor of Nottingham, and successfully held the town against enemies without and intrigue and calumny from within till the close of the struggle. About the beginning of the year 1646 he was sent up by Nottingham to fill his father's place in the parliament, and later sat as one of the commissioners in the High Court of Justice for the king's trial, and signed the warrant for his execution. He sat in the first council of state, but gradually became alarmed at the ambitious schemes of Cromwell, and ceased to take an active part in politics. At the Restoration, along with other regicides, he was included in the Act of Amnesty, but later was imprisoned for about a year in the Tower and at Sandown Castle in Kent on a groundless suspicion of treasonable conspiracy, and died 11th September 1664. The *Memoirs*, written by his widowed wife for her children, was first published in 1806, and revealed to the world a delightful picture of a grave and courteous gentleman, beautiful and accomplished; tender to his family and the poor; fearless, frank, and honest in temper; intense in devotion, yet entirely free from austerity and fanaticism. The unsought beauty of the style, and the absolute sincerity and truthfulness of the narrative, give the book an almost unique place among English biographies, and the tender devotedness of loving memory with which throughout it is informed has still power to touch the modern reader with a thrill of sympathetic emotion.

Hutia. See HOG-RAT.

Hutten, PHILIP VON, a German adventurer, and a cousin of Ulrich von Hutten, was born at Birkenfeld about the end of the 15th century, and was educated at the court of Henry of Nassau. In 1528 the Emperor Charles V. made a grant of the province of Venezuela to the Welsers, a firm of rich Augsburg merchants; and Hutten sailed with one of the companies they sent out. He accompanied the viceroy, Georg Hohehut, in a long journey (1536-38), in which they reached the headwaters of the Rio Japura, near the equator. In 1541 he set out in search of the Golden City. After several years of wandering, harassed by the natives and weakened by hunger and fever, he and his followers came on a large city, the capital of the Omaguas, in the country north of the Amazons; and attacking this place, they were routed by the Indians, and Hutten himself severely wounded. He led those of his followers who survived back to Coro in 1546, where Juan de Caravajal had in the meantime usurped the office of viceroy; and by him Hutten and his lieutenant, Bartel Welser, were seized and beheaded. Eight years later the Welsers' grant was taken from them, and the rule of the Germans in Venezuela came to an end. Hutten left a narrative of his journeyings, which was published under the title *Zeitung aus Indien* (1765). See also Von Langegg, *El Dorado* (Leip. 1888).

Hutten, ULRICH VON, poet, humanist, and reformer, was born on 21st April 1488, of an old Franconian family whose seat was at Steckelberg, near Fulda. Being puny and small of stature, and of weak health, he was destined, although the eldest son, for the tonsure, and was sent in 1499 to the Benedictine monastery of Fulda. But his temperament—proud, high-spirited, impetuous, impatient of contradiction and of restraint—did not fit him for leading the religious life, and in 1504 or 1505 he fled away from the monastery. Consumed with a devouring hunger for knowledge, especially for the new Humanistic learning, Hutten sought

the chief universities of northern Germany, and finally passed by way of Vienna into Italy (1511 or 1512). During these years he was often utterly destitute, and generally ill, sustained only by his love for the New Learning and his indomitable spirit. His first works—Latin poems—were printed in 1509; and in the same year he wrote the first of his many bitter satires. From this time onwards his pen never rested; when not employed in behalf of the great cause it was busy in some private feud or quarrel. In Italy Hutten remained nearly two years. On reaching Germany he was received with distinction at the court of Albert, Archbishop and Elector of Mainz. There he first became acquainted with Erasmus, the leader of the Humanistic movement. In the spring of 1515 the fiery combativeness of Hutten's nature was roused by the murder of his cousin Hans, who had been wantonly slain by Ulrich, Duke of Württemberg. The young poet launched denunciation after denunciation at the guilty duke (published after his fall), and called upon the emperor to punish the offender; and, himself girding the sword upon his thigh as one of the army of vengeance his family had raised, threatened war upon the duke. His friends then sent him back to Italy to study law. At Rome and at Bologna he spent nearly two years, and came home to enter the service of the Archbishop of Mainz. It was at this time that he wrote his most important work, his share of the *Epistolæ Obscurorum Virorum* (q.v.).

Having been formally crowned poet-laureate of Germany by the Emperor Maximilian at Augsburg in 1517, Hutten began the real work of his life, his deliberate assault upon papal aggressiveness, in an ironical dedication to Leo X. of a new edition of Laurentius Valla's exposure of the fictitious Donation of Constantine. When he first heard of Luther's revolt, Hutten looked upon it as a mere monks' quarrel. In 1519 he took part, along with his subsequent friend and patron, Franz von Sickingen, in the campaign of the Swabian League against his old enemy, Duke Ulrich of Württemberg. But this concluded, he returned to the attack upon the papal power. The ideal that possessed his soul was to create a national Germany, delivered from the hateful interference, extortion, and spiritual tyranny of supercilious priests from beyond the Alps. But he also aimed at an intellectual reform of the so-called learned classes, through the spread of the New Learning, and at the cultivation of refinement in the habits and manners of his countrymen. At length he came to understand the real significance of Luther's action, and, at once joining hands with him, he espoused the reformer's part with his customary impetuosity and vehemence. Henceforward he was more closely identified with the Reformation than with the Humanistic movement. A set of dialogues which he published in 1520 contained *Vadicus*, his formal manifesto against Rome. This at last stung the pope to take retributive measures, and he caused the archbishop to dismiss Hutten from his service. Hutten found shelter in Sickingen's strong castle of Ebernburg in the Palatinate, whence during the next two years he discharged a perfect shower of invectives, denunciations, and satires at the heads of the papal party, and wrote appeal after appeal to the German emperor, the princes and nobles, bishops, scholars, and people, urging them to shake off the tyrannous domination of the enemies of their country. And in order to get at the common people he began to write in the vernacular, his earliest work in German being *Aufwecker der deutschen Nation* (1520), a poem in which Hutten's satiric powers reach their highest pitch. Sickingen's castle having become unsafe, Hutten fled in 1522 to Basel, where

he was greeted with marked coldness by Erasmus. This estrangement shortly afterwards gave rise to a bitter epistolary quarrel. At Basel Hutten was again attacked by the odious disease from which he had suffered since boyhood; and, after seeking a safe retreat at Mühlhausen and at Zurich, was befriended by Zwingli, who found him an asylum on the little island of Ufnau in the Lake of Zurich. There Hutten ended his stormy life in 1523.

His writings fall into three divisions: (1) Latin poems (1509-16); (2) letters and orations (1515-17); and (3) dialogues and letters, including his German writings (1517-23). See his *Opera Omnia* (7 vols. 1859-62), and books by Schott (1890), Szamatolski (1891), and Strauss (1914).

Hutten, LEONHARD, champion of Lutheran orthodoxy, was born in 1563 at Nellingen, near Ulm, and filled the chair of Theology at Wittenberg from 1596 till his death in 1616. His *Compendium* (1610) took the place of Melancthon's *Loci*, and his *Concordia Concors* (1614) was long a standard work. His name was adopted by Hase (q.v.) in his well-known rehabilitation of the Old Lutheran dogmatic, *Hutterus Redivivus* (1828).

Hutton, CHARLES, mathematician, son of a superintendent of mines, was born at Newcastle-upon-Tyne, 14th August 1737; from 1755 to 1773 was a teacher at Jesmond and Newcastle, and published works on arithmetic (1764), mensuration (1771), and bridges (1772). In 1773 he was made professor of Mathematics at the Military Academy, Woolwich, and in 1774 became F.R.S. His calculations for determining the density of the earth from Maskelyne's observations were published in the *Philosophical Transactions* for 1778. He resigned the professorship in 1807; and he died 27th January 1823.

Hutton's most important works are *Tables of Products and Powers of Numbers* (1781), *Mathematical Tables* (1785), *Mathematical and Philosophical Dictionary* (1795), *Course of Mathematics* (1798-1801), and *Recreations in Mathematics and Natural Philosophy* (4 vols. 1803—largely from the French).

Hutton, JAMES, one of the founders of geology, was born at Edinburgh, 3d June 1726. He studied medicine in his native city and at Paris and Leyden, but on his return home (1754) he settled in Berwickshire and devoted himself to agricultural pursuits and to chemistry, from which he was led to mineralogy and geology. In 1768 he removed to Edinburgh, and there spent his time in scientific investigations, and there he died, 26th March 1797. He read two important papers before the Royal Society of Edinburgh, *A Theory of the Earth* (1785; expanded to 2 vols. in 1795; vol. iii. 1899) and *A Theory of Rain* (1784). The upraised land of the globe must, he thought, be worn away by atmospheric influences, and the debris be finally deposited in the bed of the sea, where it is consolidated under great pressure; it is then forced upwards by subterranean heat acting with an expansive power, and thereby split and cracked, the fissures at the same time filling with molten mineral matter; and so the process goes on. The formation of rain he ascribed to the mingling of two strata of air of different temperatures and the subsequent condensation of the mixture.

He also wrote *Dissertations in Natural Philosophy* (1792), *Considerations on the Nature of Coal and Culm* (1777), and other works. See GEOLOGY, PLATEAU.

Hutton, RICHARD HOLT (1826-97), son and grandson of Unitarian ministers, was born at Leeds, studied at University College and School, London, and under Martineau at the Manchester New College. He was for some time a Unitarian preacher, became principal of University Hall, and contributed to Unitarian periodicals. Under the

influence of F. D. Maurice he joined the Church of England, edited the new quarterly *National Review*, and taught mathematics in Bedford College. About 1860 he and Mr Townsend became associated as joint-editors of the *Spectator* (founded in 1828), to which he gave the impress of his accomplished, resolute, devout mind. He revered Cardinal Newman; had constant regard to ethical and religious interests in his judgments of men and movements, whether literary, social, or political; and greatly strengthened opposition to Irish Home Rule. His *Studies in Parliament* (1866), *Essays, Theological and Literary* (1871; new ed. 1888), and *Modern Guides of English Thought* (1887) were republished from the periodicals; his monograph on Scott was his least effective publication. His last years were clouded by the melancholia of his second wife, who, like his first, belonged to the Liverpool Roscoe family.

Hutukhtu. See MONGOLIA, LAMAISM.

Huxley, THOMAS HENRY, biologist, born at Ealing, Middlesex, 4th May 1825, commenced his education at the school in that place, then a small village, and afterwards studied medicine in the Medical School of Charing Cross Hospital. In 1846 he entered the medical service of the royal navy, and did duty at Haslar, until the winter of the same year, under Sir John Richardson, by whose influence he was appointed assistant-surgeon of H.M.S. *Rattlesnake*. This vessel, commanded by Captain Owen Stanley, was commissioned to survey the intricate passage within the Barrier Reef skirting the eastern shores of Australia, and to explore the sea lying between the northern end of that reef and New Guinea. Huxley devoted himself with zeal to the study of the numerous marine animals collected during the survey, and made them the subjects of scientific papers, which were published by the Royal and Linnean societies. Towards the end of 1850 the *Rattlesnake* returned to England, and Huxley had the gratification to find that his paper 'On the Anatomy and Affinities of the Family of the Medusæ' had been published in the *Philosophical Transactions*. In 1851 Huxley was elected a Fellow of the Royal Society; in 1852 one of the two Royal medals annually given by the Society was awarded to him; and in 1853 he contributed to the Society's *Transactions* a memoir on the morphology of the Cephalous Mollusca. In 1854 he was appointed professor of Natural History, including Palæontology, in the Royal School of Mines, and held that office, combined with the curatorship of the fossil collections in the Museum of Practical Geology, until 1885. It was part of the duty of the professor to deliver a course of six lectures to working-men every alternate year. Some of these have been published. In 1854 he published contributions to the anatomy of the *Brachiopoda*, in which some hitherto unsuspected peculiarities of their structure were described; and in this and the preceding year he wrote several essays on histological subjects. In 1856 he accompanied his friend Dr Tyndall on his first visit to the glaciers of the Alps, and his name appears as joint-author of a paper, 'Observations on Glaciers' (*Phil. Trans.* 1857). In 1859 his large work on *The Oceanic Hydrozoa; a Description of the Calyptrophoridae and Physophoridae* observed during his voyage, was published by the Ray Society with illustrative plates. After his appointment to the Royal School of Mines Huxley's attention was chiefly directed to vertebrate morphology and to palæontology, with occasional excursions into the region of ethnology; but papers on the agamic reproduction and morphology of *Aphis* (1858), on the development of *Pyrosoma* (1860), a manual of

the Invertebrata (1877), and classification and distribution of Crayfishes (1878) are evidence that the Invertebrata were not neglected. In vertebrate morphology the most important papers are the Royal Society's Croonian lecture, *On the Theory of the Vertebrate Skull* (1858); various papers on the brain in man and apes, and on the relation of man to the lower animals, and *Man's Place in Nature* (1860-63); on the classification of Birds, and on the *Dinosauria* (1868-70); the article 'Amphibia' in *Ency. Britannica* (1875); *On Ceratodus* (1876); the cranial and dental structure of the *Canidae* (1880); *Lectures on Comparative Anatomy* (1864); *An Introduction to the Classification of Animals* (1869); in paleontology, besides various papers on other fossil Invertebrata, memoirs on *Pterygotus* (1858) and *Belemnites* (1864); a series of papers on *Stagonolepis Robertsoni* and *Hyperodapedon Gordoni* (1859-77-87); preliminary essay and descriptions of Fossil Fishes in the Decades of the Geological Survey (1862); *Glyptodon* (1863); Neanderthal Skull (1864); Reptilian Remains from India (1864); *Telerpeton* (1866); Amphibia from the Kilkenny Coal-measures (1867-71); *Hypsilophodon* and Evidences of Affinity between Reptiles and Birds (1869-70); *Chelonina* from Lord Howe Island (1887); in physiology, a short treatise, *Lessons in Elementary Physiology*. Essays on topics of a philosophical and general character are collected in *Lay Sermons*, &c. (1870); *Critiques and Addresses* (1873); *American Addresses and Physiography* (1877); a short work on *Hume* (1879); *Science and Culture* (1881); and *Science and Hebrew Tradition* (1894). His collected essays, with an autobiography, were issued in 9 volumes in 1893-95. A member of the Privy Council since 1892, he died at Eastbourne, 29th June 1895. His son Leonard wrote his *Life and Letters* (2 vols. 1900). Sir Michael Foster and Sir E. Ray Lankester edited his *Scientific Memoirs* (4 vols. and supplement, 1898-1903). Huxley strongly advocated and greatly furthered Darwin's views and evolutionist doctrines in general, and was a keen and incisive critic of what he regarded as obscurantist theological prejudices. He was examiner in the university of London, Fullerian professor at the Royal Institution, Hunterian professor of Comparative Anatomy at the Royal College of Surgeons. He was elected in 1873 Lord Rector of the university of Aberdeen, and a member of the London School Board in 1870.—LEONARD HUXLEY, born 11th December 1860, studied at University College School, St Andrews University, and Balliol College, Oxford. He was assistant to the professor of Greek at St Andrews, a master at the Charterhouse, publisher's reader, and editor of the *Cornhill Magazine*. Besides his father's *Life* he wrote a *Life of Sir Joseph Hooker* (1918), *Anniversaries and other Poems* (1920), translations, &c.—His eldest son, JULIAN SORELL HUXLEY, born 22d June 1887, educated at Eton and Balliol, lectured on Zoology at Houston, Tex., and Oxford, took part in the Oxford-Spitsbergen expedition 1921, and wrote *Essays of a Biologist* (1923) and many articles.—A younger son of Leonard Huxley, ALDOUS LEONARD HUXLEY, born 26th July 1894, was educated at Eton and Balliol, was on the staff of the *Athenæum* and of the *Westminster Gazette*, and wrote poetry of great beauty—*The Burning Wheel* (1916), *The Defeat of Youth* (1918), *Leda* (1920); fiction, *Limbo* (1920), *Crome Yellow* (1921), *Mortal Coils* (1922), *Antic Hay* (1923), *Those Barren Leaves* (1925); and essays, *On the Margin* (1923).

Huy, a town of Belgium, is romantically situated amid lofty rocks on both banks of the Meuse, 19 miles SW. of Liège by rail. Its old citadel, whose works are partly excavated in the solid rock, erected to command the passage of the river, has long been disarmed. The church of Notre

Dame, a graceful Gothic edifice, was begun in 1311. In the vicinity are ironworks and coal-mines, and the manufactures include paper, leather, beer, spirits, &c. Pop. 15,000. Peter the Hermit founded here the former Abbey of Neufmoustier (*Norum Monasterium*), and here in 1115 he died. Huy has been frequently besieged.

Huygens, CHRISTIAAN, a very great mathematician and physicist, was born at The Hague, 14th April 1629, and was the second son of Konstantijn Huygens, poet, diplomatist, and secretary to the Prince of Orange, who was knighted by James I. of England in 1622. Huygens studied at Leyden and Breda. His first work, *Theorematum de Quadratura Hyperboles, Ellipsis, et Circuli* (1651), is an example of that powerful geometrical talent which lay at the foundation of all his scientific achievements. Soon after this he constructed the pendulum-clock, following out the idea first suggested by Galileo (see **HOROLOGRY**). A complete description of Huygens' instrument is contained in his great work, *Horologium Oscillatorium* (1673). This work contains expositions of many of the cases of constrained motion, especially those applicable to the construction of timekeepers. Huygens also developed and gave precision to the investigations of Galileo upon accelerated motion under the action of gravity; and there is no doubt that to the clearness of his demonstrations his great successor, Newton, in preparing his magnificent development of the principle of accelerating force, was largely indebted. Newton was a student and admirer of his works, and assigns to him, along with Sir C. Wren and Wallis, the distinguished epithet of *hujus ætatis geometrarum facile principes*. By means of an improved telescope of his own construction, Huygens in 1655 discovered the ring of Saturn and the fourth satellite of that planet. In 1659 he published an account of these discoveries in a work entitled *Systema Saturnium*. In the end of this work the Micrometer (q.v.) is described. In 1660 Huygens visited England, where he was admitted a member of the Royal Society. He discovered the laws of collision of elastic bodies about the same time as Wallis and Wren, and also made a material improvement in the air-pump. But his most important discoveries are in the department of optics: he it was who first propounded and developed what is now known as the undulatory theory of Light (q.v.), and he is the discoverer of Polarisation (q.v.). The 'principle of Huygens' is a part of the wave-theory. In 1666 Huygens received an invitation to settle in France, with the promise of a pension from Colbert, then all-powerful in that country. At Paris he remained till 1681, a member of the Royal Academy of Sciences; but alarmed at the danger which seemed impending over the Protestants, he returned to his own country, and died at the Hague, 8th July 1693. His *Œuvres Complètes* have been issued since 1888 by the Amsterdam Academy of Sciences.

Huysmans, JORIS KARL (1848-1907), novelist, was born the son of a Dutch father at Paris, and for some years held a post in the French ministry of the interior. His first novel, *Sar au Dos* (1872), was followed by a series, all full of Zola's realism, till 1895, when his works began to breathe a spirit of Catholic mysticism.

Huysum, JAN VAN (1682-1749), Dutch painter, was born and died at Amsterdam. His landscapes are conventional and artificial, but his fruit and flower pieces are exquisite.

Huzvares, the non-Iranian element in the Pehlevi dialect. See **ZEND**.

Hwen-thsang, or HIOUEN-THSANG, or YUAN CHWANG, a Buddhist monk of China, who was born near Honan about 605, and in 629 set out

on a pilgrimage to India, travelling by the Desert of Gobi, Tashkend, Samarkand, Bamian, and Peshawar. He remained thirteen years in India (631-44), visiting the sacred places of his religion, and studying its sacred books. He died in 664 in a convent at Chang-ngan (now Singan). Owing to the many curious notices he gives of matters which came under his observation, and the high degree of trustworthiness which his narrative possesses, his memoirs are regarded as one of the most important works on the history of India in general, and of Buddhism in particular, during the period stated. The account of his travels, written under his supervision, was completed in 648. It was translated into French by Stanislas Julien. See also Shaman Hwui Li, *Life of Hsuen Tsiang* (trans. 1914), and Watters, *On Yuan Chwang's Travels* (1904-5).

Hyacinth (*Hyacinthus*), a genus of plants of the natural order Liliaceæ; bulbous-rooted plants with corolla-like, bell-shaped, 6-cleft perianth, six stamens fixed in the tube of the perianth, and dry capsular fruit. The flower was fabled to have sprung from the blood of the beautiful Spartan Hyacinthus, beloved of Apollo and Zephyrus.

Zephyrus, jealous because Hyacinthus favoured Apollo, caused Apollo's quoit to strike and slay the beautiful youth while the two were at play.—The Oriental Hyacinth (*H. orientalis*), one of the most favourite of florists' flowers, is a native of Asia Minor, Syria, and Persia. It is now naturalised in some parts of the south of Europe. It has broad linear leaves, and a scape with a raceme of many flowers pointing in all directions. The flowers in cultivation exhibit great variety of colour, chiefly blue, purple, and white. They are very beautiful and very fragrant. The fragrance is strongest about or after eleven o'clock at night. Among cultivated hyacinths are many with double flowers. The hyacinth has been cultivated from a remote period. It was introduced into Europe, probably by the Dutch, about the beginning of the 16th century, soon after the revival of commerce, when the traders of Holland carried their merchandise to the eastern shores of the Mediterranean and the Archipelago. It was very little known in Britain till towards the beginning of the 17th century, but soon after its cultivation had become a passion with the wealthy, as it had for some time been with the Dutch. Extravagant prices were paid for a single bulb of varieties having special or rare merits. This passion declined towards the middle of the 18th century, and the cultivation of the hyacinth became very much depressed. Now, however, it forms one of the principal industries of florists around Haarlem, the centre of the Dutch bulb trade; but their efforts are directed with the view of meeting the demand of the million rather than the special requirements of the fanciful wealthy few. Hyacinth bulbs, planted in pots, readily produce beautiful flowers; and flowers almost equally beautiful are obtained—for one year only, however—by placing them in water in hyacinth-glasses, in which they form a favourite ornament of apartments in winter and early spring.

Hyacinth
(*Hyacinthus orientalis*).

The cultivation of hyacinths in the open ground is much more difficult, their early growth being liable to be destroyed by adverse weather. New varieties are raised from seed. Several other species of hyacinths are natives of the south of Europe, Africa, &c.—The Grape-hyacinth and Globe-hyacinth, frequently cultivated as garden flowers, are now referred to the genus *Muscari*.—A common British plant, growing in woods and copses, with beautiful blue flowers very like those of the oriental hyacinth, but all drooping to one side (*H. non-scriptus*, also known as *Scilla nutans*, *Endymion nutans*, and *Agraphis nutans*), is sometimes called the Wild Hyacinth, and sometimes the Blue-bell (q.v.). The bulbs have been used for making starch.—The name is also given to varieties of garnet, topaz, sapphire, and zircon. See JACINTH.

Hyacinthe, PÈRE, is the former monastic name of CHARLES LOYSON, born at Orleans, 10th March 1827. He studied at St Sulpice, and in 1851 becoming priest, taught philosophy and theology at Avignon and Nantes. Subsequently entering the order of the Carmelites, he became known as a powerful preacher, and gathered crowded and enthusiastic audiences of all ranks of society to the Madeleine and Notre Dame in Paris. Almost as remarkable as his eloquence was the boldness with which he denounced existing abuses in the church; and Archbishop Darboy defended him against the accusations of the Jesuits till in 1869 the General of his order imposed silence on him. Hyacinthe replied by a letter in which he called for a thorough reform of the church, and was excommunicated. Relieved from monastic vows by the pope, he became a secular priest under the name of the Abbé Loyson. He protested vigorously against the Infallibility Dogma; but although he attended the 'Old Catholic' Congress at Munich, and on visits to the United States and England fraternised with Protestants, he always declared his intention to remain in the Catholic Church, trying to obtain reforms. In 1872 he married an American lady (author of *To Jerusalem through the Lands of Islam*, 1905). In 1879 he established a 'Gallican' congregation in Paris, which in 1884 attached itself to the Old Catholic Church, and ultimately to the Jansenist Church. He published sermons, polemical lectures, and books on his own theological position. He died 9th February 1912.

Hyades, in Greek Mythology, the nurses and guardians (3, 5, or 7 in number) of young Dionysus. Zeus converted them into stars and transplanted them to the heavens, where they form the head of the constellation Taurus. Their rising with the sun was held in Greece to mark the beginning of the rainy season.

Hyæna, a genus of digitigrade carnivorous quadrupeds, included in the genus *Canis* by Linæus, but now referred to the *Æluroid* division of the Carnivora, of which it is a somewhat aberrant member, forming with *Proteles* (see AARD-WOLF) a sub-family, Hyænina. Hyænas have six incisors and two canine teeth in each jaw, five molars on each side in the upper jaw, and four in the under. They seize an object with so firm a hold that, among the Arabs, they are proverbial for obstinacy. The vertebrae of the neck sometimes become ankylosed in old hyænas. The hind-quarters are lower and weaker than the fore-quarters of the body, so that hyænas move with a shambling gait. The body is covered with rather long coarse hair, forming a mane along the neck and back. The feet have each four toes. The claws are strong, fit for digging, and not retractile. The tail is rather short. Beneath the anus is a deep glandular pouch, contributing much to the offensive odour by which hyænas are characterised. Hyænas eat carrion, as

well as newly-killed prey, and are of much use, like vultures, as scavengers, clearing away the last remnants of carcasses that if left to rot would greatly pollute the air. They sometimes attack cattle, especially if they flee, but rarely man, though they sometimes seize children. During the day they hide themselves in caves, old rock-tombs, ruined edifices, &c.; by night they roam singly or in packs in quest of prey. They prowl about towns and villages, and often dig up corpses that have not been very deeply buried. This, together with their aspect and manners, has caused them to be generally regarded with horror, and very exaggerated accounts of their fierceness have been prevalent. Instead of being untamable, as was long the popular belief, they are capable of being very completely tamed, and show an attachment to man similar to that of the dog; they have even been used as watchdogs. Hyænas are found only in Africa and the south of Asia, not extending to the farthest east of the latter continent.—The Striped Hyæna (*H. striata*) is found both in Asia and Africa, and there are several varieties considerably different in size, colour, &c. The smallest hyænas are of the size of a large dog. The Spotted Hyæna (*H. crocuta*) inhabits South Africa. It is rather smaller than the largest varieties of the striped hyæna, but is more fierce and dangerous. It is called Tiger-wolf by the colonists of the Cape of Good Hope.

Spotted Hyæna (*Hyæna crocuta*).

Besides its ordinary howling, which it emits very freely in its nocturnal roamings, this hyæna often indulges in an expression of gratification or of some passion, resembling hysterical laughter, whence it has acquired the name of the Laughing Hyæna. The general colour is ochry gray, with thinly scattered small round brown spots, and sooty muzzle and feet. The Woolly Hyæna (*H. brunnea*) is a smaller South African species.

In consequence of the bones which hyænas eat, their dung forms solid yellowish-white balls, of compact earthy fracture, the *Album græcum* of the old materia medica. For the Hyæna Dog, see DOG.

Hya-hya. See COW-TREE.

Hybla, the name of three cities of ancient Sicily. (1) An old Sicilian town situated on the southern slope of Mount Etna, which figured in the second Punic war; its site is fixed at the modern Paterno.—(2) A city founded by the Megarians about 726 B.C., and probably identified with the city called Megara. It was destroyed by Gelon of Syracuse in 481 B.C. It is believed to have stood near the modern Agosta.—(3) A third Hybla lay between Syracuse and Agrigentum. The Hyblean honey, so much sung by Latin poets, was gathered on the hills near the first two cities.

Hybrid (Gr. *hybris*, 'lust'), the offspring of two parents which belong to different varieties, or to different species, or even to different genera.

Thus, according to the degree of divergence between the parents, variety-hybrids or mongrels, species-hybrids (the usual application of the term), and genus-hybrids, which are very rare, have to be distinguished. It is also useful to note with Broca that hybridisation may be (a) *natural*—i.e. occurring in undisturbed natural conditions, of which we know relatively few cases; (b) *incited*—i.e. under direct human control, on which our data as regards animals are chiefly based; and (c) *artificial*—i.e. by placing the pollen of one plant on the stigma of another species, or by mixing with the eggs of some animal, say frog or fish, the male elements of some related form.

Among mammals genus-hybrids find illustration in the successful crossing of lie-goat (*Capra*) and ewe (*Ovis*), the offspring being fertile for several generations, both *inter se* and with the parent-stocks. Species-hybrids are well illustrated in the results of crossing various members of the genus *Equus*—e.g. male ass and mare, the offspring being a mule; or horse and female ass, the offspring being a hinny. Similarly, dog and fox, dog and jackal, lion and tiger, hare and rabbit, Indian humped cattle and our very different domesticated breeds, and not a few other more or less nearly related forms have been successfully crossed.

Among birds the common duck (*Anas boschas*) and a pintail (*Dafila acuta*), the common goose (*Anser ferus*) and the very distinct Chinese goose (*A. cygnoides*), goose and swan, canaries and finches, pheasant and hen, and other allied forms are recorded as giving rise to hybrids. Among lower animals hybrids also occur; different species of toad are often seen in sexual union, but the result is unknown; the artificial fertilisation of frog ova with the sperms of other species has at least resulted in the development of hybrid tadpoles; in several fishes hybridisation seems to occur in natural conditions, and artificial fertilisation has been effected even between genera, to the extent at any rate of starting the development of the ova. The hybrids of two moths (*Bombyx cynthia* and *B. arindia*) have been recorded as fertile *inter se* for eight generations. Hybrids have been obtained between different genera of Echinoderms—e.g. between *Echinus* and *Echinocardium*.

Hybrids between pure-bred stocks with contrasted characters—e.g. tall and dwarfed peas, banded and handless snails, gray and albino mice—often illustrate Mendelian inheritance. The hybrids resemble one parent in respect of a given character; the progeny of the inbred parents include both the parental types. See HEREDITY.

Hybridisation in Plants.—Experiment is here much easier, and a large mass of data has rewarded the investigations of Kölreuter (1761), Andrew Knight, Dean Herbert, Gärtner, Wichura, Hildebrand, Focke, and others. The subject received careful discussion from Darwin in his work on cross-fertilisation, and also from Nägeli, a summary of whose conclusions is available in the English translation of Sachs's *Text-book of Botany*. Only the leading results can be noted here. Hybridisation rarely occurs except between forms known to be related; variety-hybrids occur easily and abundantly; species-hybrids are less, though quite common; genus-hybrids (e.g. between the grasses *Ægilops* and *Triticum*, between the Caryophyllaceous genera *Lychnis* and *Silene*) are rare. Besides genetic relationship, some subtle harmony, which we can only call 'sexual affinity,' is essential to successful hybridisation. When one species can be fertilised by the pollen of another, the *vice versa* relation usually holds good; but sometimes the hybridisation is persistently one-sided. Kölreuter easily obtained seeds from *Mirabilis jalapa* with the pollen of *M. longiflora*, while

more than two hundred experiments, extending over eight years, with the pollen of the former upon the stigma of the latter were futile. The results of hybrid-fertilisation exhibit many degrees; thus, the mother-plant may be affected by the strange pollen without seeds being produced, or seeds may be formed which will not germinate, or numerous, vigorous, and fertile hybrids may result. When two kinds of pollen are simultaneously applied to the stigma only one kind is potent. The hybrid is usually intermediate between the two parents, not only in structural features, such as the venation of the leaves and the shape of the flower, but in physiological peculiarities, such as the time of flowering and the mode of coloration. Focke reports a curious case where the crossing of *Anagallis cærulea*

A, leaf of *Salix caprea*; B, of *S. viminalis*; C, of hybrid between these two species. (After Wichura.)

and *A. phænicea* produced hybrids which bore in part the blue flowers of the former species, and in part the reddish flowers of the latter. Hybrids are usually more variable than the parents, and the variation may be towards strength or towards weakness. Since Fairchild, at the beginning of the 18th century, first intentionally produced a cross between *Dianthus barbatus* and *D. caryophyllus*, hybridisation has often been resorted to by gardeners and arboriculturists to produce a strong stock. Very important are the numerous hybrids between European and American vines, some of which are believed to be endowed with greater powers of resisting Phylloxera and fungi than the unaltered European plants possess. There can be no doubt that species-hybrids among plants tend to be sterile, and this the more the wider the difference between the parent plants. Sometimes three or even six individualities have been gradually mingled in a multiple hybrid, and this lessens still more the chance of fertility.

Character of Hybrids.—The products of crossing, whether of species or of varieties, are undoubtedly very variable, sometimes for the better—as in many of our domesticated mongrels among both animals and plants—very often on the other hand for the worse. They are often so unstable that they tend rapidly to die out, as has been observed among some human experiments in mingling races. The saying ‘God made the white man, God made the black man, the devil made the mulatto,’ expresses a feeling as to the frequently inconvenient variability of variety-hybrids, but there is much to be said on the other side. Such a case as sheep-goat hybrids shows how far from accurate is the still prevalent belief that hybrids from widely-separated parent forms must be sterile. We are by no means warranted in saying more than that species-hybrids tend to be sterile so far as we

know them, and that it must be remembered is for the most part in conditions of domestication, where the resulting sterility may have been due to confinement, and to prolonged interbreeding, rather than to the hybridisation itself. Nor do the facts allow us to accept the further generalisation that variety-hybrids are always fertile. Not only are there cases of the reverse, but, as Wallace justly points out, the conclusion was again based on domesticated forms, in regard to which it must be noted that the very first essential to their becoming domesticated was that they should continue fertile under changed conditions of life.

Hybrids in Relation to Evolution.—The facts of hybridism raise some of the most intricate problems connected with evolution. As only a few general statements can be noted here, the reader is referred to the cited work of Alfred Russel Wallace. (1) Fertility or non-fertility of crosses must not be exaggerated into the test between variety and species, for all species-hybrids are not sterile, nor all variety-hybrids fertile. (2) Fertility depends on some delicate mutual adjustment or complementariness of the male and female elements, and is readily disturbed by external or constitutional conditions. (3) Animals seem to prefer to breed with their like among existing varieties, and in this way it is believed that the ‘swamping effects of intercrossing’ have been usually obviated, though mutual infertility and geographical separation may also assist in preserving the varieties. (4) Brooks has laid stress upon the fact that both variety and species hybrids are highly variable. In his theory of ‘physiological selection,’ Romanes has emphasised the importance of mutual sterility in splitting up one species into several. ‘Whenever any variation in the highly variable reproductive system occurs, tending to sterility with the parent form without impairing fertility with the varietal form, a physiological barrier must interpose, dividing the species into two parts, free to develop distinct histories, without mutual intercrossing, or by independent variation.’ (5) Darwin concluded that ‘the sterility or infertility of species with each other, whether manifested in the difficulty of obtaining first crosses between them, or in the sterility of the hybrids thus obtained, was not a constant or necessary result of specific difference, but is incidental on unknown peculiarities of the reproductive system.’ Wallace has advanced a step further in his endeavour to show that ‘if we accept the association of some degree of infertility, however slight, as a not unfrequent accompaniment of the external differences which always arise in a state of nature between varieties and incipient species, natural selection has the power to increase that infertility just as it has the power to increase other favourable variations.’

Hydaspes. See JHELUM.

Hydatid (from the Greek *hydatis*, ‘a watery vesicle’), the bladder-worm stage of certain tapeworms, but particularly of *Tænia (Echinococcus) echinococcus*, found in cattle, sheep, pigs, &c., and

sometimes in man, in the liver, lungs, or other organs. The bladder-worm (*Echinococcus veterinorum*) varies from the size of a pea to that of a child's head, weighing in some cases 12 to 30 lb.,

A, brood-capsule of *Echinococcus veterinorum*, with fully-formed and rudimentary heads; B, adult *Tænia echinococcus*.

and is notable for its prolific asexual multiplication. From the inner surface, in numerous special brood-capsules of the size of millet-seed, sometimes hundreds of 'heads' are budded off; while daughter-bladders may also be formed externally. The tapeworm is very small ($\frac{1}{4}$ inch or so), with only three joints; it occurs in large numbers in the intestine of dog, or wolf, or jackal. When the dog is kept too much about the house it becomes possible for the developing eggs to get on to food or dishes, and thus into man. The disease is known in most countries of Europe; it is common in Iceland and Australia. The term hydatid is sometimes extended to other bladder-worms—e.g. the 'stagger-worm' (*T. cænurus*) of the sheep, or in medicine to serous cysts which have nothing at all to do with parasites. See TAPEWORM and BLADDER-WORM. Leuckart's *Parasites of Man* (trans. by W. E. Hoyle, vol. i. Edin. 1886).

Hyde, an important manufacturing town of Cheshire, 7 miles ESE. of Manchester, and 5 NE. of Stockport. Standing in a coalfield, and enjoying ample facilities of communication by road, rail, and canal, it has risen from a mere village to a considerable town, which in 1881 was incorporated as a municipal borough. Cotton is the staple manufacture; then come the felt-hat industry, engineering, boiler-making, &c. The town-hall and municipal buildings are handsome. Pop. (1811) 1806; (1861) 13,722; (1901) 32,768; (1921) 33,437.

Hyde, EDWARD. See CLARENDON (EARL OF).

Hyde Park. See LONDON.—HYDE PARK, Mass., is now part of Boston.

Hyderabad (*Haidarābād*), or the NIZAM'S DOMINIONS, a great native or feudatory state of India, occupies the greater part of the Deccan proper or central plateau of southern India, between the provinces of Madras and Bombay. Area, 82,700 sq. m. (excluding the British assigned districts of Berar, q.v.); pop. (1881) 9,845,594; (1921) 12,471,770. About a tenth only are Mohammedans, found mainly in the capital, though the Nizam and state are Mohammedan. Telugu, Kanarese, Marathi, and Urdu are the principal languages spoken. Education has made rapid strides. Agriculture has developed much in consequence of the extension of irrigation works and the building of railways throughout the state. The surface is a slightly-elevated tableland. The principal rivers are the Godavari, with its tributaries the Dudna, Manjira, and Pranrita; and the Kistna (Krishna), with its tributaries the Bhima and Tungabhadra. The soil is in general very fertile, but poorly cultivated; yet, wherever it receives moderate attention, it yields harvests all the year round. The products are rice, wheat, maize, mustard, castor-oil, sugar-cane, cotton, indigo, fruits (including grapes and melons), and all kinds of kitchen vegetables. The pastures are extensive, and sheep and horned cattle

are numerous. The climate is good on the whole. The mean temperature of the capital, Hyderabad, in January is 74° 30', and in May 93°. The exports are cotton, oil-seeds, cloth, hides, metal wares, and agricultural produce. Coal, copper, iron, gold, and diamonds are found, but not extensively worked.

In 1687 the territory long known as the Nizam's Dominions became a province of the Mogul empire; but soon after 1713 the governor or viceroy of the Deccan, Asaf Jah, with the title of *Nizam-ul-Mulk* ('regulator of the state'), made himself independent. After his death, in 1748, two claimants appeared for the throne, his son Nasir Jang, and his grandson Muzaffar Jang. The cause of the former was espoused by the East India Company, and that of the latter by a body of French adventurers under General Dupleix. Then followed a period of strife and anarchy. In 1761 Nizam Ali obtained the supreme power, and after some vacillation signed a treaty of alliance with the English in 1766. He aided them in the war with Tippon, sultan of Mysore, and at the termination of that war, in 1799, a new treaty was formed, by which, in return for certain territorial concessions, the East India Company bound itself to maintain a subsidiary force of 6000 men for the defence of the Nizam's dominions. Another treaty was concluded in 1853. The Nizam, who in point of rank is the first Mohammedan ruler in India, remained faithful to the British during the mutiny of 1857–58 (see JUNG, SIR SALAR). The assigned districts (see BERAR) were in 1861 given in trust to Britain on account of debts; leased in perpetuity in 1902; incorporated with the Central Provinces in 1905.

Hyderabad (*Haidarābād*), the capital of Hyderabad state, stands on the right bank of the Musi, at an elevation of 1700 feet above the sea, by rail 390 miles NW. of Madras. It is 6 miles in circumference, and is surrounded by a stone wall, flanked by bastions. In 1921 the population, inclusive of the suburbs, was 404,187. The populace consists of very varied elements, and is full of warlike spirit, nearly every one carrying weapons. The street architecture is uninteresting. The palace of the Nizam, though architecturally of no great importance, is of vast size. Hyderabad is one of the most important strongholds of Mohammedanism in India, and the mosques are numerous. The principal mosque was fashioned after the model of the Great Mosque at Mecca; in the interior are fine monolithic granite columns, and outside the building is crowned by very lofty minarets. Another remarkable edifice is the Char Minar or College, with four minarets resting on four connected arches, at which the four principal thoroughfares converge. On the opposite side of the river is the British Residency, a magnificent pile, with the finest staircase in India; it stands in the midst of fine ornamental gardens, and communicates with the Nizam's palace by a bridge with eight spacious arches of squared granite. The neighbourhood boasts of wild and picturesque scenery, and abounds with huge tanks and beautiful gardens.—Secunderabad (*Sikandarābād*) is a British military cantonment six miles to the north-east of Hyderabad.

Hyderabad, the historical capital of Sind and chief city of a district, stands $3\frac{1}{2}$ miles E. of the left bank of the Indus. Pop. (1921) 81,838, of whom 25,000 were Mohammedans. The town is the main centre of postal, telegraphic, and road communication for the province, though the Sind railway, terminating at Karachi, is on the other side of the Indus. It is famous for the manufacture of silks, gold-work, pottery, lacquered ware, and arms of various kinds. There is now a plentiful water-supply from the Indus. As against a

native force it is tolerably strong, occupying a somewhat steep height, and having a rampart flanked by round towers.

Hyder Ali (*Haidar Āli*), ruler of Mysore, and one of the greatest Mohammedan princes of India, was born in 1728. His grandfather was a wandering fakir; his father a constable of a district in Mysore. Hyder spent his youth in idleness, though occasionally doing military service; but in 1749 his bravery at a siege attracted the notice of the maharajah of Mysore's minister. He soon became in all but name ruler of the kingdom; and in 1759 he dispossessed his master, allowing him to retain his title, while he himself took that of *daiva*, or regent. He then conquered Calicut, Bednor, Kananur, and other neighbouring states; and in 1766 his dominions included more than 84,000 sq. m. He withheld the customary tribute from the Mahrattas (q.v.), and carried on an ultimately successful war against them. He waged two wars against the British, in the first of which (1767-69) he was practically successful, and signed a treaty under the walls of Madras, which provided for a kind of alliance. When Hyder was defeated by the Mahrattas in 1772 he claimed English support; and on the refusal of the Madras government to fulfil what he believed to be the treaty obligations, he became the bitter enemy of the English. Taking advantage of the war between the English and French (1778), he and his son and successor, Tippoo Saib, descended like a thunderbolt into the Carnatic, totally routed two English commanders, and ravaged the country to within forty miles of Madras; but he was ultimately defeated in three battles by Sir Eyre Coote. He died suddenly, still in alliance with the French, in December 1782. See L. B. Bowring, *Haidar Ali and Tipu Sultan* (1893).

Hydnora, a genus of parasitic plants belonging to the order Hydnoraceæ, which consists entirely of root-parasites. *Hydnora africana* is a South African species parasitic on the roots of fleshy Euphorbiæ and other succulent plants; it has a putrid smell, but is roasted and eaten by the natives, and is also used for tanning.

Hydnum, a genus of fungi belonging to the sub-order Hymenomycetes, order Basidiomycetes, and having the under side of the *pileus* covered with soft spines which bear the spores. The species are numerous, some of them British; among these is *H. repandum*, more common in some parts of the continent of Europe, and much used as an esculent in France, Italy, and Germany. It grows chiefly in pine and oak woods.

Hydra, a Greek island, lies 4 miles from the coast of the Peloponnesian department of Argolis and Corinth. It is a narrow rocky ridge, 11 miles long, 1960 feet high, and 20 sq. m. in area. The shores are rocky and steep, and the interior is destitute of vegetation and of water. On the north-west coast is the seaport of Hydra. The islanders, mostly of Albanian origin, make excellent seamen, and carry on cotton and silk weaving, tanning, shipbuilding, sponge-fishing, and commerce. The island was uninhabited in ancient times. Previous to the war of Greek independence the Hydriotes numbered more than 28,000, and were considered the richest people in the archipelago. They enjoyed a large share of the carrying-trade in the Black Sea and the Mediterranean, and traded to England, the Baltic, and even America. In the war they took a most active and conspicuous part; but on the restoration of peace the island lost much of its former prosperity, being outtrivalled by Syra.

Hydra, a fabulous monster of the ancient world, said to have inhabited the marshes of

Lernæa, in Argolis, not far from the sea-coast. Accounts vary both as to its origin and appearance. Some make it the issue of Styx and the Titan Pallas, and others of Echidna and Typhon. It is represented as having several heads, which immediately grew up again as often as they were cut off. The number generally ranged from seven to nine, though Simonides gives it fifty, and some historians a hundred, and even more. Its mouths, which were as numerous as its heads, discharged a subtle and deadly venom. The destruction of this reptile was one of the twelve labours of Herakles. It may be that a basis for the myth is to be found in some large octopus or other cuttlefish.

Hydra, a genus of fresh-water polyps, of world-wide representation, in the class Hydrozoa, within the phylum Cœlentera. Hydra is one of the very few exceptions to the rule that Cœlenterates are marine animals, and it is somewhat too simple in its structure to be taken as a type of the class to which it belongs. But it is a readily procurable

Fig. 1.

Semidiagrammatic longitudinal section of an adult specimen, with reproductive organs and a bud (*a*); magnified eight diameters. (After Marshall and Hurst.)

and very interesting animal, and will therefore be described in some detail. There are a number of species—the green *Hydra viridis*, the brown *H. fusca*, the pale *H. vulgaris*, and others. They are found attached, by the base of their tubular body, to aquatic plants, often to the lower surface of duckweed.

The body is as thin as a needle, $\frac{1}{2}$ to $\frac{1}{4}$ inch in length, able to contract into a minute knob. The mouth is raised on a little cone, and is surrounded by 6 to 10 mobile hollow tentacles. There are no organs except those concerned in reproduction—a number of testes just below the origin of the tentacles, and usually an ovary or ovaries towards the base. The mouth leads into the blind food-canal (cœlenteron), the cavity of which is continued into the tentacles. As in other Cœlenterates, there is no trace of a body-cavity or cœlom. The wall of the body is at the same time the wall of the food-canal, and consists of two layers of cells—the transparent external ectoderm, and the usually coloured internal endoderm. The two layers are separated by a structureless middle (mesogloal) lamella. In technical language, the hydra is diploblastic, whereas all animals above the level of Cœlentera have a middle layer of cells (mesoderm) and are called triploblastic. The ectoderm consists

of a considerable variety of cells—(a) large covering or epithelial cells, some of which (b) have muscular basal processes running longitudinally; (c) stinging cells or cnidoblasts, between or pressed into (a), each containing a long coiled stinging lasso or nematocyst, which can be explosively thrown out;

Fig. 2.

A, a nematocyst with the thread not everted; highly magnified. B, a nematocyst, after the evagination of its contents; highly magnified. The lasso, if completed on the scale of the drawing, would have a length of 12 inches. (After Gibson.)

(d) very minute nerve-cells and sensory cells; (e) small interstitial cells, chiefly between the bases of (a), which seem capable of developing into reproductive, stinging, and other kinds of cells; and (f) granular glandular cells on the basal disc or 'foot,' probably secreting a glutinous substance, and also said to be capable of protruding amoeboid processes, and thus of moving the hydra along. The stinging cells, which are restricted to Coelenterates, are especially abundant on the tentacles, and are used in paralysing and gripping small animals. The hollow lassoes are barbed at their base, and are evaginated with great velocity, penetrating even a firm skin. Their action is partly mechanical, partly chemical. The stinging cells die after explosion. Besides the ordinary stinging cells, there are small ones whose nematocysts coil into a spiral after explosion. It is hardly necessary to say that the hydra is carnivorous; it may be sometimes seen using its tentacles to push victims into its mouth. The cells of the endoderm are not so varied as those of the ectoderm. They are more or less pigmented and markedly vacuolate; they bear flagella (used in producing currents) and amoeboid processes (used in engulfing food); some of them have muscular roots, running in a transverse direction; a few near the mouth and base are glandular, some of them producing digestive juice. For the hydra is interesting in showing two kinds of digestion—intracellular and extracellular. In the former, food particles are engulfed by the endoderm cells and then digested; in the latter, the food particles or small organisms are digested in the usual way in the food canal, and the results then absorbed. As to the colour of the endoderm cells, those of *H. viridis* contain minute green bodies, which certainly contain chlorophyll, and are usually regarded as unicellular algae living in symbiosis with the hydra. In the other species of hydra the pigment is quite different from chlorophyll.

In favourable conditions of nutrition and temperature the hydra forms buds, mainly due to multiplication of interstitial cells. Each bud is a replica or reproduction of the parent. On the buds of the first order a second generation of buds may be developed, and curious multiple forms are sometimes seen. A check to nutrition or some similar influence leads to a constriction at the base of the bud, which is thus liberated as an independent animal. A budding hydra transferred to water without food may absorb its bud. In rare cases a hydra may divide transversely across the middle, and each half grows into a complete polyp in a few days. It is important to notice that the multiplication of hydra in any pond or stream is due to this asexual reproduction, for the polyp often produces (as is normal in *H. viridis*) only one egg-cell at a time, and the development is slow. As to the

sexual reproduction, there are some interesting facts. Both male and female organs may occur on the same animal, either at one time or at different times, and there may be self-fertilisation or autogamy, which is of very rare occurrence among animals (see FLUKE and TAPEWORMS). On the other hand, there are often individuals with only testes or with only an ovary. It seems that purely female forms are more frequent when food is very abundant. The ovum of hydra is the successful central cell of the ovary; it is at first very markedly amoeboid, but as it exploits its neighbour-cells it becomes spherical, and protrudes from the ovary. It is fertilised and falls off, or is fastened to water-weed. In all species the separation from the parent is followed by a period of enshelled quiescence for four to eight weeks, and during this stage the egg may be carried by winds or floods or birds' feet from one water-basin to another.

The name Hydra was applied to fresh-water polyps because cutting them in pieces multiplied their numbers, as happened when the heads of the fabulous hydra were hacked off. The first detailed account of the hydra's regenerative capacity was given by the Abbé Trembley in 1744, and few corrections have to be made to the vivid account which he gave of his experiments. A hydra may be multiplied by being cut in pieces, but the two conditions of a fragment regrowing a whole polyp are: (1) that the fragment be not too small, and (2) that it be a fair sample of the various kinds of cells in the body. Thus neither a little corner off the base nor the tip of a tentacle will regrow a new hydra, though what is lost is, of course, repaired. The Abbé Trembley made the delicate experiment of turning a hydra inside out, and concluded that the out-turned inner layer eventually assumed the characters of the ectoderm, and that the intumed ectoderm put on the characters of the endoderm. But this never happens. The hydra with its tentacles cut off and the tubular body turned inside out may rapidly right itself by turning outside in, or, if this be prevented, the intumed ectoderm disappears internally, and by growing over the out-turned endoderm, from the mouth-margin downwards, restores the normal state of the two layers.

The hydra spends most of its life attached to water-weed, swaying, expanding, and contracting its body, capturing small animals by means of its mobile tentacles. It can glide slowly on its base, or loop along by alternately fixing and loosening the mouth and the base. Mechanical stimulation is followed by withdrawal of the tentacles and by contraction of the body. But contact with a solid edible object (probably implying chemical as well as mechanical stimulation) leads to seizure by the tentacles. If the polyp is very hungry it will exhibit this positive food reaction in response to unprofitable as well as profitable stimulation.

Even simpler than hydra is Protohydra, a polyp without tentacles, occurring both in the sea and in fresh water. An American fresh-water form, *Microhydra ryderi*, is known to liberate free-swimming medusoids. A strange simple polyp, *Polypodium*, occurs as a parasite on the eggs of sturgeons. A number of fresh-water medusoids (*Limnocoedium*, *Limnocoidea*) are known.

Hydragouges. See APERIENTS.

Hydrangea, a genus of plants of the natural order Hydrangeaceae, which many make a sub-order of Saxifrageae, distinguished by having four to six petaloid sepals, eight to twelve or many stamens, a more or less inferior ovary, and two to five styles. In *Hydrangea* the flowers are in cymes, the exterior flowers sterile and dilated. The species are chiefly natives of the southern parts

of North America, and of China and Japan. The species popularly known as the Hydrangea (*H. Hortensia*) is a native of China and Japan, and has long been in cultivation there as an ornamental plant. It was introduced into Britain by Sir Joseph Banks in 1788, and speedily became very popular, being readily propagated by layers and cuttings, so as to be not only a favourite greenhouse plant, but a frequent ornament of cottage windows. In the south of England and south-west of Scotland it endures the open air. It seems almost impossible to water it too freely; and in favourable circumstances it becomes a magnificent shrub. A plant in Devonshire has had 1000 large cymes of flowers expanded at once. The flowers, generally pink, are sometimes blue; the blue colour is owing to peculiarities of soil. Peat and iron ore are said to be productive of blue

Hydrangea (*Hydrangea Hortensia*).

flowers in the hydrangea.—*H. radiata* and *H. quercifolia*, American species, are not unfrequently to be seen in flower-gardens in North America. *Formosa* has given us some magnificent new hydrangeas—*H. glabrifolia*, *H. integra*, *H. Kowakamii*, *H. obovatifolia*—besides other species; and south-west China has contributed even more novelties to the genus.

Hydrastis, a small genus (Japanese and North American) of Ranunculaceæ. *H. canadensis* is golden seal.

Hydrates are compounds of water with elements or with other compounds. The term *hydroxide* is one which is sometimes used as a synonym of *hydrate*, and indeed it may be said that we have no certain means of distinguishing the one from the other. The distinction between the two is that in the hydrate the water is supposed to be present as water, and without any rearrangement of the molecules, while in the hydroxide the water is considered to have lost its identity, its constituent atoms having entered into new combinations. As a typical example of a hydrate we may instance crystallised sulphate of copper, $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, which contains the water so loosely combined that it is driven off by prolonged heating, and the white anhydrous sulphate, CuSO_4 , is produced. Here the water is apparently present as water, and necessary to the crystalline form, and is therefore called water of crystallisation. When nitric anhydride, N_2O_5 , unites with water it forms nitric acid, $\text{N}_2\text{O}_5 \cdot \text{H}_2\text{O}$ or HNO_3 , but this is not regarded as a hydrate, because the nitric acid cannot lose the water without also losing its characteristic properties. The whole question is full of difficulties, and is at present quite theoretic-

cal; different chemists using the terms above mentioned in different senses.

Hydraulic Cranes. See CRANES.

Hydraulic Engines or Motors are often conveniently used when water under a high pressure is obtainable, and where work is intermittently required, as in capstans, winches, &c.; they do not differ essentially from steam-engines. The water acts by difference of pressure—i.e. it is admitted at a high pressure at the beginning of the stroke, and exhausted at a low pressure at the end of the stroke, thus giving a reciprocating motion to the plunger. The velocity of the piston has to be kept low to avoid injurious shocks in suddenly bringing the column of water to rest; since they work under very much greater pressures than steam-engines (usual pressure 700 lb. per sq. in.), they can be much smaller. A common form is the three-cylinder single acting engine: in each cylinder works a plunger; water is admitted by valves behind the plungers and forces them out; at the conclusion of the out-stroke the pressure water-supply is cut off, and the exhaust valve opened, allowing the plunger to push the water out of the cylinder on the return stroke, and so on. There are two chambers in the framing, and one passage or port into the bottom of the cylinder; during the working of the engine the cylinder oscillates, and at the right time puts one or other of the two chambers in communication with the interior of the cylinder by means of this port; one chamber is open to exhaust-pipe, the other to supply-pipe. The plungers are connected to a three-throw crank. The great advantage of the single action is that shocks are avoided at the dead centres; the three cranks ensure a very uniform turning force on the crank shaft, and also enable the engine to start in any position.

Hydraulic Main. See GAS.

Hydraulic Mortar. See CEMENTS.

Hydraulic Press, often called Bramah's press, from the inventor, Joseph Bramah (q.v.), depends for its action on the principle that a pressure exerted on any part of the surface of liquid is transmitted undiminished and equally

Hydraulic Press.

in all directions through the mass (see HYDROSTATICS). The annexed figure represents the essential parts of the machine, minor details of construction being omitted. F is a strong cast-iron or cast-steel cylinder, open at the top; B is a plunger or ram which fits watertight into the cylinder; to prevent leakage a leather ring U-shaped in section is placed in the cavity c; any water trying to leak out forces the two sides of this ring hard against the piston and the side of the cavity, and the greater the pressure the tighter it keeps. This form of packing is now

often replaced by an ordinary stuffing-box filled with hemp packing. A pipe, G, leads from the cylinder to a force-pump, H. By means of this pump water can be forced from the tank, T, through the pipe G into the cylinder, thus pushing the plunger or ram, B, upwards. The ram carries on its top a platten or table, on which the bales, &c., to be pressed are placed; the rising of the platten presses them against the entablature or upper plate, A, which is held in position by the columns C. The bale can thus be squeezed to any extent desired.

The power of the press is readily calculated; let the diameters of the pump-plunger, K, and ram, B, be d and D inches respectively, then any downward pressure on K becomes an upward pressure on B magnified $\frac{D^2}{d^2}$ times. Suppose, for instance, that

the pressure on K was 500 pounds, and that the diameters are 1 and 10 inches respectively, then the upward thrust would be $500 \times \frac{10^2}{1^2} = 50,000$ pounds;

very enormous pressures are therefore readily obtained, and in consequence of the slow motion there is extremely little waste of power in friction. It is thus a very efficient mechanism. The pump can either be a hand-pump worked by a lever, L, as in sketch, or it may be worked by a steam-engine, as is the case in the modern powerful presses. The enormous multiplying power of this contrivance has led to its most extensive use; for example, compressing cotton and wool bales, &c., expressing oils, bending iron plates and bars, lifting heavy weights (lifts and hoists), raising into position bridge-girders (hydraulic jacks), &c. Presses of enormous power are now superseding the huge steam-hammers in large steelworks, obviating the unpleasant vibrations and ensuring sounder metal.

Hydraulic Ram, a simple and conveniently applied mechanism, by which the energy of water falling from a height, h , can be made available to force a portion of itself to a greater height, h' . There is a supply-reservoir, fed, say by a spring, from which a strong pipe, R, conducts the water to the ram at a lower level. The ram has two valves, one, A, opening downwards and inwards, the other, B, opening upwards and outwards; the weight of these valves is such that when the water is at rest its normal pressure is unable to keep them from falling, so that in this condition A would be open and B shut. A cottar on the rod of A keeps it from opening more than a certain amount, and this can be adjusted; the valve B

Section of Hydraulic Ram.

opens into an air-vessel, C, from the bottom of which the delivery pipe, D, leads away. The action is as follows: the water flows from the reservoir through the pipe R, and rushes out through the now open valve A away to the waste-pipe; in doing

so it acquires considerable velocity, and its pressure therefore on the under side of the valve A increases, and finally becomes great enough to close it. The flow of the water being thus suddenly checked produces a great reaction, and by its momentum opens the valve B, and forces a portion of the water into the air-vessel C; the energy being expended, the pressure falls again, B closes, and A opens once more, enabling the water to rush out to the waste-pipe, and so the whole operation is repeated. The two valves thus alternately open and close, and water is delivered each time into the air-chamber, C, the air in which being compressed acts as an air-cushion, keeping up a constant delivery through the pipe D. The small air-vessel, E, is for diminishing the shocks, and has a small relief valve in it to admit air when necessary; it is self-acting. The hydraulic ram was an invention of Montgolfier (1797), but has been greatly improved; its mechanical efficiency is good, and for raising small quantities of water, such as are necessary for the supply of single houses, farm-yards, &c.—where water at the lower level is plentiful and cheap—it is a most useful piece of mechanism. It can even be made to work a pump, and so to deliver a supply of pure water when the motive water is muddy or impure.

Hydraulics. See HYDROMECHANICS.

Hydrides are compounds formed by the union of hydrogen with metals and non-metals. The latter are fairly stable compounds, the former are unstable. The more important hydrides are those: phosphorus, PH_3 ; arsenic, AsH_3 ; antimony, SbH_3 ; nitrogen, NH_3 . Calcium hydride, CaH_2 , is known as hydrolith, and is a ready means of preparing hydrogen by the action of water on it.

Hydriodic Acid. See IODINE.

Hydroaeroplane. See BALLOONS AND AEROPLANES.

Hydrobromic Acid, (1) gas, HBr , invisible, pungent, acid reaction, fumes in moist air, liquid at -69°C ., solid at -100°C .; prepared from a bromide plus phosphoric acid, or phosphorus tribromide plus water. (2) Aqueous solution, analogous to commercial hydrochloric acid, is weakened by boiling until HBr sinks to 47 per cent., then distils unchanged. See BROMINE.

Hydrocarbons belong to the department of organic chemistry, and may be shortly defined as compounds of carbon and hydrogen, and nothing else. Despite their apparently simple nature, they are frequently very complex, and exist in such numbers as to bewilder the beginner in chemical study. Fortunately, they can be gathered into groups, each having distinctive characters, and the members of which are closely related to each other. The chief of these are the Paraffins, the Olefines, the Acetylenes, the Benzene (q.v.) series, and the Anthracene (q.v.) group.

The *Paraffins* are found in natural petroleum as well as in the products of the destructive distillation of coal, and are known as *saturated hydrocarbons*. By this is meant that the carbon present is already saturated (so to speak) with hydrogen, and has no tendency to unite with other elements or molecules. Graphically, carbon may be represented as —C— i.e. with four bonds, each one of which is capable of being united to one atom of hydrogen; and when all four bonds are so united, a *paraffin* is

produced; thus, $\text{H—}\overset{\text{H}}{\underset{\text{H}}{\text{C}}}\text{—H}$. But, instead of the single atom of hydrogen, one bond (or all the bonds) may be engaged by such a group as CH_3 , so that we get another paraffin, $\text{CH}_3\text{—CH}_3$. Thus we go on forming a series, each member of which differs from

the preceding one in having an extra CH_2 . Thus :

and so on indefinitely. It will, however, be noticed that when we pass to a higher member than propane, by replacing an atom of hydrogen by CH_3 , we may do so in two ways, according as the atom replaced is in the CH_3 group at either end, or the CH_2 group in the centre. The result is that two hydrocarbons are possible—viz. $\text{CH}_3-\text{CH}_2-\text{CH}_2-\text{CH}_3$, and also $\text{CH}_3 > \text{CH}-\text{CH}_3$. In like manner,

as we proceed further, wider scope is given to us, the result being that when Tridecane, $\text{C}_{13}\text{H}_{28}$, is reached, it is theoretically possible to recognise 802 such bodies, all having the same percentage composition, but differing more or less in characters. Many of these isomers are already known. The paraffins are characterised by their indifference to chemical action, being unacted on by caustic potash, sulphuric or nitric acid. The general formula of the paraffins is $\text{C}_n\text{H}_{2n+2}$, where n represents the number of atoms in the formula.

The *Olefines*, C_nH_{2n} .—The chief of these are Ethylene, C_2H_4 , Propylene, C_3H_6 , Butylene, C_4H_8 , Amylene, C_5H_{10} , &c.; and it will be observed that in all of them the percentage composition is identical, and that each member differs from the lower one by the addition of CH_2 . When acted on by chlorine, bromine, or iodine they readily form oily liquids, such as Dutch liquid, and, generally speaking, they markedly differ from the paraffins in the readiness with which they unite with other bodies.

Hydrocele (Gr. *hydōr*, 'water,' and *kēlē*, 'a swelling') is a dropsy of the tunica vaginalis, the serous membrane investing the testis. It occurs as a smooth, pear-shaped swelling, painless, but sometimes causing a slight uneasiness from its weight. The quantity of fluid in the sac may amount to 40 ounces. Hydrocele may occur as a result of acute inflammation, but it most commonly comes on without any apparent local cause. It is most frequently met with about or beyond the middle period of life, and generally in persons of feeble power, or with a tendency to gout; sometimes, however, it occurs in young children, either in the same form as in adults, or as what is termed *congenital hydrocele*. The treatment may be *palliative* or *curative*. The palliative treatment consists in the use of suspensory bandages, and tapping from time to time. Tapping seldom gives more than temporary relief, the swelling usually regaining its former bulk in a few months. The curative treatment consists in setting up inflammation in the tunica vaginalis, by the injection of tincture of iodine, so as to obliterate the cavity, or with greater certainty by excision of the sac.

Hydrocephalus. Under this term, which literally means 'water in the head,' are popularly designated two quite distinct diseases, acute hydrocephalus, which is a tuberculous manifestation, and chronic hydrocephalus, an inborn peculiarity which gradually advances with the progress of years.

Acute Hydrocephalus, or, as it is more satisfactorily termed, *tubercular meningitis*, is an inflammation of the membranes of the brain caused by the tubercle bacillus. The disease is most common in children under ten years of age, but may affect adults, particularly those suffering from an advanced stage of lung tuberculosis. It occurs especially among children living under bad hygienic conditions, or among those who have recently suffered from some acute disease, particularly measles or whooping-cough. Also it shows sometimes a marked tendency to affect several members of one family at intervals, it may be, of several years.

As regards symptoms, tubercular meningitis is usually described as passing through three stages after certain premonitory symptoms, but its manifestations are very vague, and one or more of the stages may be omitted. The *premonitory symptoms* that usher in the disease may last from a few days to several weeks. The patient, if a child, becomes listless and easily fatigued, loses appetite, complains of headache after exertion, and may become peevish and irritable. The commencement of the *first stage*, or stage of excitement, is usually marked by vomiting, often severe, and there may be convulsions. Headache is one of the most constant symptoms, and is frequently accompanied by paroxysms in which the patient screams out with a peculiar sharp cry characteristic of meningitis. There is great intolerance of light and of loud sounds, much restlessness, rubbing of the head against the pillow, and general sensitiveness. The temperature is raised to about 101° or 103° F.; but the pulse is not quickened, being rather slow and irregular—a sign very characteristic of meningitis. The symptoms of this stage usually last from one to two weeks. In the *second stage*, or stage of depression, the patient becomes quieter, inclines to sleep, and may appear to be improving; but this quietness is simply a state of apathy or mental stupor. The eyes show dilated and unequal pupils responding very little to light, and there is often partial or complete blindness. Squinting is also very frequently noticed in this stage, and there may be drooping of an eyelid, both symptoms due to affection of the nerves to muscles of the eye. In the *third stage*, or stage of paralysis, there is an exacerbation of the symptoms, often with convulsions; the body becomes greatly emaciated, and there is often paralysis of a limb, a group of muscles, or even the whole of one side of the body. Death takes place frequently in a fit or simply from general exhaustion. The duration of a case of tubercular meningitis varies, but is usually about three or four weeks from the onset of definite symptoms, and recovery is extremely rare. On post-mortem examination tubercles are found in the membranes of the brain, especially at its base and round the blood-vessels of the surface. The irritation thus set up causes the effusion of fluid into the arachnoid membrane and into the ventricles within the brain. This, by its pressure, tends to interfere with the circulation, and to produce degeneration and softening of the brain substance.

With regard to treatment, little can be done beyond the employment of measures designed to relieve the patient's sufferings. In the matter of prevention, however, it is most important in families where the history indicates a tubercular tendency, and especially where meningitis has already occurred in other members of the family, that every effort should be made by wholesome food, warm clothing, regulation of the natural functions, and the avoidance of over-exertion, physical and more especially mental, to avoid the causes which predispose to its onset. Care should be taken to avoid the tubercle bacillus by boiling or otherwise sterilising the supply of milk during the first decade of the child's life. When the symptoms have become so prominent that the diagnosis is beyond doubt, the administration of sedatives like bromide of potassium, or even morphia, is the chief requirement. For convulsions the inhalation of chloroform may be necessary. Cold or counter-irritants applied to the head help to relieve the headache, and the slight operation known as lumbar puncture, by which some of the excess of fluid within the meninges is withdrawn, has a similar effect. In the early stages tuberculin injection has been tried, though it is doubtful whether any benefit has accrued from its use.

Chronic Hydrocephalus is a perfectly distinct disease from that just described; while the latter is an inflammation, the former is a dropsy. In chronic hydrocephalus a watery fluid collects within the skull, before the bones have united to form the solid brain-case, and by pressure outwards causes them to separate, and increases the size of the head sometimes to an enormous extent. Thus while the ordinary circumference of the adult head is about 22 inches, a hydrocephalic skull in the Museum of the Faculty of Medicine at Paris measures 39 inches. While the skull is rapidly enlarging, the bones of the face grow no faster than usual, and the great disproportion of size between the head and the face is at once diagnostic of the disease. This disorder sometimes commences before birth, and almost always in early childhood, before the fontanelles and sutures of the skull have closed. In some rare cases it has occurred later, as, for example, at seven or nine years old, and the closed sutures have opened under the augmenting pressure. When the sutures will not yield, death from pressure on the brain speedily ensues. Most children with chronic hydrocephalus either recover or die in infancy; but a few survive, bearing their complaint to adult life, or even to old age. Blindness, deafness, palsy, and idiocy—one or more—are commonly associated with this disease, but occasionally the intellect and senses are sufficiently perfect for the ordinary requirements of social life.

The results of treatment are generally not encouraging, though sometimes benefit appears to result. Medical treatment most in favour consists in the administration of diuretics, purgatives, and especially mercury. The surgical expedients are puncturing the head and ligaturing the main blood-vessels of supply to the brain (carotid arteries). The latter has in many cases certainly prolonged life.

This disease occasionally occurs in adult or in advanced life, after enlargement of the head has become impossible. Stupor, paralysis, and an inability or unwillingness to speak are in these cases the most prominent symptoms. Dean Swift's death was attributed to this disease, and it is recorded that during the last three years of his life he remained generally in a state of silence.

Hydrocharitaceæ, or HYDROCHARIDÆÆ, an order of monocotyledons (Helobiae), temperate and tropical water-plants, some of them marine (e.g. *Halophila*, which is pollinated under water). The flowers are unisexual, the plants commonly dioecious. The ovary is inferior. The genera include *Hydrocharis* (see FROGBIT), *Elodea* (see ANACHARIS), *Stratiotes* (see WATER-SOLDIER), *Vallisneria* (q.v.).

Hydrochloric Acid (sym. HCl; equiv. 36.5) is one of the most important compounds in inorganic chemistry. If the two gases which enter into its composition (hydrogen and chlorine) be mixed in equal volumes they will remain without action upon each other if kept in the dark; but as soon as they are brought into direct sunlight they unite with a loud explosion, and hydrochloric acid gas is the result. The principal characters of this gas are that it is colourless, intensely acid, irrespirable, and even when largely diluted is very irritating to the lungs and eyes, and very injurious to vegetation; that it is heavier than air (its specific gravity being 1.2474, air being taken at 1.000); that it can be condensed into a colourless liquid; that it is very soluble in water, and that it is neither combustible nor a supporter of combustion. When allowed to escape into the air it produces white fumes by condensing the

atmospheric moisture. If the air be previously dried no such fumes are apparent.

The solutions of this gas in water form the acid which was first known as *Spirit of Salt*, then as *Muriatic Acid*, and which is now termed *Hydrochloric Acid*. A saturated watery solution of this gas at 40° F. (4.4° C.) has a specific gravity of 1.21, and consists of 1 equivalent of the gas dissolved in 3 equivalents of water. It forms a colourless, fuming liquid, which acts as a corrosive. On heating it the gas is evolved abundantly until the temperature reaches 230° F. (110° C.), when there distils over a diluted solution, having a specific gravity of 1.1, and consisting of 1 equivalent of the gas and 8 equivalents of water. It is to these solutions of hydrochloric acid that the term *hydrochloric acid* is far more commonly applied than to the gas itself. They possess the ordinary characters of an energetic acid, and neutralise the strongest bases. The neutralisation is, however, not in consequence of the acid combining with the oxide, but is due to the simultaneous decomposition of the acid and of the oxide, water and a metallic chloride being formed. If M represents the metal the reaction is expressed by the equation $M_2O + 2HCl = 2MCl + H_2O$. All metals which at a red heat decompose water also decompose this acid, and cause an evolution of hydrogen, the reaction being expressed as follows: $M + HCl = MCl + H$. Hydrochloric acid gas is a common gaseous volcanic product. Free hydrochloric acid in a very dilute form is also a constituent of the gastric juice of man and animals, and plays an essential part in the digestive process.

Commercial *muriatic acid*—to use the name employed by manufacturing chemists—is made by heating in iron cylinders common salt (chloride of sodium) and oil of vitriol (hydrated sulphuric acid), and condensing the evolved gas in water contained in a series of stoneware Wolfian Bottles (q.v.), the reaction being explained by the equation:

This commercial acid may contain various impurities—as, for example, iron, which gives it a bright deep yellow colour), the chloride of sodium and arsenic—the latter being derived from the oil of vitriol—sulphuric and sulphurous acids, chlorine, &c., from which it can be purified to a great extent by dilution and redistillation. 'If pure,' says Miller, 'the acid should leave no residue when evaporated; on saturating it with ammonia it should give no precipitate of oxide of iron; sulphuretted hydrogen should produce no turbidity in it, which would be the case if arsenic, free chlorine, or sulphurous acid were present; and on dilution with three or four times its bulk of water no white cloud of sulphate of baryta should be produced by the addition of chloride of barium.' The presence of hydrochloric acid, or of the soluble chlorides in solution, may be detected by the addition of a few drops of a solution of nitrate of silver, which occasions the formation of a white curdy precipitate of chloride of silver, which is insoluble in nitric acid, but dissolves in a solution of ammonia. For chloride of calcium, see LIME.

Liquid hydrochloric acid (under the name of spirit of salt) was known to the alchemists. Hydrochloric acid gas was discovered by Priestley in 1772; and Davy in 1810 ascertained that it was composed of chlorine and hydrogen. In many respects hydrobromic, hydrofluoric, and hydriodic acids resemble hydrochloric acid.

Hydrocleys, a Brazilian water-plant (*H. nymphoides*, or *Limncharis Humboldtii*) of the Butomaceæ, resembling a water-lily.

Hydrocyanic Acid, HCN, known also as Prussic Acid, from its having been first obtained by Scheele in 1782 from the substance called Prussian Blue, is of almost equal interest to the chemist, the physician, and the toxicologist.

(1) *Chemistry*.—Pure hydrocyanic acid is a colourless, highly volatile liquid, with a specific gravity of 0.697 at 64° F. It boils at 80°, and solidifies into a crystalline mass at 5° F. It possesses a very penetrating odour, resembling that of peach-blossoms or oil of bitter almonds. It burns with a whitish flame, reddens litmus paper slightly (its acid properties being feeble), and is very soluble in water and alcohol. Pure hydrocyanic acid may be kept unchanged if excluded from light, which occasions its decomposition, and the formation of a brown substance known as paracyanogen. Hydrocyanic acid is readily obtained by distillation from the kernels of bitter almonds and many kinds of stone-fruit, from the leaves and flowers of various plants, and from the juice of the tapioca plant (*Jatropha manihot*). Anhydrous hydrocyanic acid may be obtained by the action of concentrated hydrochloric acid on cyanide of mercury. The diluted hydrocyanic acid of the British and other pharmacopœias is, however, of more practical importance. It is made (*British Pharmacop.*) by distilling ferrocyanide of potassium with dilute sulphuric acid, and is standardised to a strength of 2 per cent. When kept for any length of time it is extremely apt to decompose.

The ordinary tests for hydrocyanic acid are (1) the peculiar odour; (2) the nitrate of silver test—there being formed a white precipitate of cyanide of silver, which is soluble in boiling nitric acid; (3) the formation of Prussian blue, by adding to the fluid under examination a solution of some proto- and per-salt of iron, then saturating with caustic potash, and finally adding an excess of hydrochloric acid, when, if hydrocyanic acid is present, we have a characteristic blue precipitate; (4) the sulphur test, which is the best and most accurate that has yet been discovered. To the suspected liquid add ammonia and yellow sulphhydrate of ammonium; evaporate the liquid in a watch-glass to dryness, occasionally adding ammonia till the excess of sulphhydrate of ammonium is decomposed. Add water, and acidify with hydrochloric acid. If hydrocyanic acid be present, the sulphocyanate of ammonium which has been formed gives a blood-red solution on the addition of a ferric salt.

(2) *Medicinal Uses*.—Diluted hydrocyanic acid is used externally as an ingredient of lotions to diminish itching in skin diseases. In 2 to 8 minim doses it is given internally to diminish irritability of the stomach, to relieve gastro-intestinal pain, vomiting, and functional palpitation of the heart. Given by the mouth or by inhalation it is also useful in allaying cough in phthisis, whooping-cough, bronchitis, &c. All these applications depend upon its action in deadening sensory nerves.

(3) *As a Poison*.—Hydrocyanic acid is one of our most energetic poisons, and is frequently employed for suicide. When a *small* poisonous dose (about a small teaspoonful of the 2 per cent. acid) has been taken the first symptoms are weight and pain in the head, with confusion of thought, giddiness, nausea (and sometimes vomiting), a quick pulse, and loss of muscular power. If death result this is preceded by convulsions and involuntary evacuations. When a *large* dose has been taken (as from half an ounce to an ounce of the 2 per cent. acid) the symptoms may commence in a few seconds, and it is seldom that their appearance is delayed beyond one or two minutes. 'When,' says Dr A. S. Taylor, 'the patient has been seen at this period he has been perfectly

insensible, the eyes fixed and glistening, the pupils dilated and unaffected by light, the limbs flaccid, the skin cold and covered with a clammy perspiration; there is convulsive respiration at long intervals, and the patient appears dead in the intermediate time; the pulse is imperceptible, and the respiration is slow, deep, gasping, and sometimes heaving or sobbing.' The patient survives for a longer or shorter period, according to the dose. According to Dr Lonsdale, death has occurred as early as the *second* and as late as the *forty-fifth* minute; the poison acts as a paralyzant to the whole nervous system. Death is due to paralysis of the heart in the more rapid cases, and to paralysis of the respiration in those which occur more slowly.

Where the fatal action is so rapid antidotes are of comparatively little value. Chlorine, ammonia, cold affusion, and artificial respiration are the most important agents in the treatment. The first two should be used with great caution, and only by the medical practitioner. Cold affusion on the head, neck, and down the spine is a valuable remedy. Artificial respiration (see RESPIRATION, ARTIFICIAL) should never be omitted.

Hydrodynamics, in its complete generality, is the science which treats of the motions and equilibrium of a material system, part or all of which is fluid. In accordance with modern dynamic nomenclature (see DYNAMICS) we should discuss it under the two headings Hydrokinetics and Hydrostatics. The historic usage of the term has, however, so fixed itself that we generally regard hydrodynamics as excluding hydrostatics and as dealing only with kinetic problems. Originally, as the derivation of the words at once show, hydrodynamics and hydrostatics referred only to the motion and equilibrium of liquids; but as our knowledge of the physical properties of all kinds of fluid, liquid and gaseous, increased, it was recognised that they had much in common from a dynamic point of view, and the terms became extended in their application as defined above. Thus the floating of a balloon in air depends on the same hydrostatic principle as the floating of a ship on water. The simpler and some of the more practical problems of hydrostatics will be found treated under that heading. In its practical engineering aspects hydrodynamics is known as hydraulics, including such important subjects as the construction of canals, breakwaters, docks, pumps, water-pipes, water-wheels, and so on, most of which have separate articles to themselves. Here we shall confine ourselves to the scientific principles of the subject, using familiar cases as illustrations.

The study of hydrodynamics has led to the conception of what is called the *perfect* fluid. It may be defined as a substance incapable of resisting the smallest deforming stress. For instance, no portion of such a fluid can resist, even for a moment, a longitudinal pressure if unsupported by a lateral pressure. The logical consequence of this definition is that, if the fluid is at rest, the pressure at a point is the same in all directions; for if it were not so there would be a deforming stress, and therefore a yielding of the fluid, and equilibrium could not exist. By similar reasoning we may show that, if the pressure varies from point to point in a fluid at rest, there must be an external force acting on the fluid in the direction in which the pressure is increasing. Thus, in virtue of gravity, atmospheric pressure decreases as we ascend, and the pressure in the ocean or any other body of water increases as we descend. So long as we are dealing with equilibrium of fluids we meet with nothing inconsistent with the definition of the ideal perfect fluid. Across every interface separating two contiguous portions of the fluid the mutual stress

is of the nature of a pressure wholly normal to the interface.

When, however, we pass to cases of fluid motion we find that the properties of the perfect fluid are very far from being realised in nature. The smallest relative motion amongst the different parts of a fluid brings into play mutual stresses which are not normal to the interface between two contiguous portions. These tangential stresses tend to destroy the relative motion, existing only so long as the relative motion exists. They are thus partly analogous to resistances due to friction in the dynamics of solid bodies—hence the term fluid friction (see *VISCOSITY*) frequently employed to denote the property that discriminates actual fluids from the ideal perfect fluid. Fluid friction, however, differs from friction in one marked particular; it has no significance in static problems. It is wholly kinetic. The gradual stilling of troubled waters, the calming of the wind, the slackening in speed of the water in a stream as we pass from the centre and surface portions towards the banks or bottom are familiar examples of the effects of fluid friction.

Under certain circumstances the tangential stresses thus brought into play not only retard the motion of the more swiftly-moving parts of the fluid, but even accelerate the motion of the more slowly-moving parts. Thus a rapidly-flowing river entering the sea draws along with it a considerable quantity of the original ocean water. The effects of a draught of air are felt far beyond the direct course of the main current. It is impossible, in fact, to mark off clearly the boundaries of a current flowing in fluid of the same kind. In like manner, the eddies formed in the wake of a solid body moving through either air, water, or other fluid could not be produced if it were not for the existence of these tangential stresses. In every case the final result is a dissipation of energy (see *ENERGY*); but in the majority of cases of practical importance the rate of dissipation is so slow—in other words, the tangential stresses are so small in comparison with the other effective forces acting—that the properties of the perfect fluid go far to explain many hydrokinetic phenomena. Some of these we shall now consider.

It has been already pointed out that the equilibrium of a fluid under the action of gravity or other force depends upon the manner in which the pressure varies in the direction of the force. Now a force has always a definite direction; and consequently in all directions perpendicular to the direction of the resultant force acting at a point in the fluid there can be no variation of pressure. Thus, from any one point we can pass to an infinity of neighbouring points at which the pressure is the same; from each of these again to an infinity of others; and so on indefinitely. We thus arrive at the conception of a surface in the fluid, at every point of which the pressure is the same. Such a surface is called a surface of equal pressure, and one of its essential properties is that it is perpendicular at every point of it to the resultant force there. In the case of fluids at rest under the action of gravity these surfaces are also called level-surfaces, and are for all practical purposes essentially horizontal planes. A consideration of these principles leads easily to the conclusion that equilibrium in a fluid mass cannot exist if the pressures at two points at the same level differ, or if the pressures are the same at two points at different levels. These two conditions are essentially one and the same; and when they are fulfilled, fluid motion must take place (see such articles as *ATMOSPHERE*, *WIND*, *WAVE*, *SIPHON*, and *ARTESIAN WELLS* for familiar illustrations of these principles).

The discharge of fluids through orifices includes

a number of very important phenomena, some of which we shall discuss in detail. The vessel MAB (fig. 1) is provided at D, C, E, *o* with apertures

Fig. 1.

which may be closed when desired. Let the vessel be filled with water up to the level MA; then, if the orifice *o*, which looks vertically upwards, is opened, a jet of water will be projected up, and will reach very nearly to the height MA. If it were not for fluid friction and the consequent dissipation of energy the jet would reach the height MA. As soon as the orifice *o* is opened, the water surface there being exposed simply to the pressure of the atmosphere is under the same pressure as the much higher surface MA. Hence a flow takes place and will continue to take place until the surface of the water MA has sunk to the level of the water at *o*. The experiment shows that the jet is projected with a velocity very nearly equal to that which would be acquired by a body falling under gravity from the level AM to the level *o*. This velocity is given by the relation $v^2 = 2gh$, where g is the acceleration due to gravity and h the difference of level mentioned. Similarly, if the orifices at D, C, E are opened, the issuing jets will be projected with speeds whose squares will be found to be very approximately proportional to the differences of level between the upper surface MA and the respective orifices. This may be proved experimentally by constructing the orifices so that the discharge is initially horizontal, and then measuring the range, BK or BL, reached by the several jets. Thus, assuming the law just given, commonly called the theorem of Torricelli, we may show that the square of the range BK is equal to four times the product of the differences in level of the orifice D below A and above B, that is, $4AD \cdot DB$. Hence if we describe a semicircle AGB on AB as a diameter, the horizontal lines DF, CG, EH meeting this semicircle will be half the horizontal ranges corresponding to the respective orifices.

The height of the free water surface above the orifice from which the water is issuing is technically called the *head*. The greater the head the greater is the pressure at the level of the orifice, and the more available the water for practical purposes. Part of the head is consumed in overcoming frictional resistances; for well-formed simple orifices about 64 per cent. of the whole head is so expended. The discharge from any orifice in a given time will depend obviously on the size of the orifice and on the available head. Experiment shows, however, that for sharp-edged orifices in a wall the discharge is distinctly less than the simple theory would indicate. In such cases the section of the jet is smaller than the section of the orifices in the ratio of about 5 to 8. This is sufficiently explained by the convergence of the streamlets in the fluid which ultimately form the jet; and this convergence continues for a little distance beyond the orifice, producing the phenomenon of the *vena contracta* or contracted vein. We have seen how the speed of

efflux is measured by means of the parabolic path of the jet; this speed multiplied by the number of seconds in a chosen interval of time, and by the *effective* (unknown) area of the orifice gives the whole discharge in that interval. This discharge can be easily measured; and thus the data are complete for finding the effective area of the orifice and comparing it with the real area. By furnishing an orifice with a short mouthpiece of the form of the contracted vein, we may regard the smallest cross-section of the mouthpiece as the true orifice. In this case the effective area and the real area are the same.

In these simple cases of efflux the energy of efflux is wholly explained as being derived from the hydrostatic head of water. The pressure due to this head is the weight of a column of water of unit-cross-section and of a height equal to the head. Thus, if ρ is the density of the water, so that ρg is the weight of unit-volume, the pressure p due to a head h is

ρgh . Thus, by Torricelli's theorem, $\frac{p}{\rho}$ is half the

square of the velocity with which a jet would be projected through an orifice made at a place where the pressure is p . Hence we may regard this ratio

$\frac{p}{\rho}$ as the energy per unit-mass of water due to the pressure p . But if the water is in motion with a speed v , its energy per unit-mass is on this account $\frac{1}{2}v^2$. If, further, the particular portion of the fluid considered is at a height x above a certain arbitrarily chosen level, defined as the level of zero potential energy, then its potential energy is gx . The whole energy possessed by the moving fluid is built up of these three parts due respectively to pressure, speed, and gravitation, and is given therefore by the expression $\frac{p}{\rho} + \frac{1}{2}v^2 + gx$. Now, in the case of a

steady frictionless flow along a determinate channel, the whole energy possessed by any unit-mass of the fluid must be the same; for at some time or other every element passes through the positions occupied at other times by other elements in the same stream-line, and passes through them under the same dynamic conditions. Hence, neglecting the effects of friction, we arrive at the conclusion that the expression for energy just given is constant along any given stream-line. Take, for example, a pipe of uniform bore. If the flow is steady the invariableness of the cross-section requires the speed at every point to be the same. Hence as x diminishes

p must increase, so that $(\frac{p}{\rho} + gx)$ may remain constant. For a horizontal pipe x must be constant, and so of necessity is p . Now suppose the tube to be horizontal but of variable section; then, since x is constant, the expression $(\frac{p}{\rho} + \frac{1}{2}v^2)$ must also be constant. But the speed v varies inversely as the section; hence p must be greatest where the bore is widest and least where the bore is narrowest. In

tration of this is shown in fig. 2, in which water is escaping from a short cylindrical nozzle A. The contracted vein occurs at c , so that, the velocity being greater there than at the open end of the tube, the pressure is less. But the pressure at A is the atmospheric pressure; and, consequently, if a tube be led from c to the vessel of water V, the water will be pushed up to some point b by the excess of the atmospheric pressure over the pressure at c .

When the effects due to friction are taken into account we see in a general way that the energy, instead of remaining constant as we pass along a stream-line, will steadily fall off. In the case of a uniform pipe this loss of energy will show itself in a more rapid falling away in the pressure. For instance, in a horizontal pipe of uniform bore the pressure will steadily diminish as we pass along in the direction of the flow. At the open end of the pipe (e , fig. 2) the pressure is that of the atmosphere; and this will gradually increase as we pass along the pipe against the flow until we come to d , where the pressure falls a little short of that due to the head of water in the vessel. This may be shown experimentally as indicated in the figure, in which the small upright tubes inserted in the horizontal pipe become filled with water to a certain height. In the construction of water-works these and many other problems in hydrokinetics receive their practical solution. In the motion and flow of highly compressible fluids, such as gases, we meet with theorems similar to those just discussed for liquids. The treatment, however, is necessarily more abstruse, and is far from complete if thermodynamic considerations are left out of account. See GAS, SOUND, THERMODYNAMICS.

The hydrokinetic problems connected with the motion of solids through fluids have their most important applications in questions which concern the artilleryman and the builder of ships and aircraft. In the practice of gunnery the law of the resistance to projectiles in air has been very fully worked out. At very high speeds it is very great indeed; and it may be shown that an ordinary-sized projectile if dropped from an immense height (say 40 miles) could never, under the action of gravity alone, attain a speed of 800 feet per second. One great source of loss of energy of a body moving through a liquid is the formation of eddies and vortices in its wake. These are the direct result of tangential stresses acting between contiguous portions of the fluid moving with different speeds. In virtue of the same tangential stresses the eddying motions quickly die away, and the energy, as in all such transformations, takes the form of heat.

Hydro-extractors. See DRYING-MACHINES.

Hydrofluoric Acid. See FLUORINE.

Hydrogen (sym. H; atom. wt. 1.008; Gr. *hydōr*, 'water,' and *gennao*, 'to produce') is an elementary gas and the lightest substance known. It is colourless, odourless, and non-poisonous, although as ordinarily prepared it frequently contains traces of disagreeably smelling or of poisonous impurities. The gas when subjected to moderate pressure at an extremely low temperature can be reduced to the liquid and solid states. In combination with oxygen it forms one-ninth part by weight of water, and it is a most important constituent of the tissues of animals and plants. It enters into the composition of a large number of manufactured substances and products used in the arts, medicine, &c., as, for instance, starch, sugar, vinegar, gutta-percha, alcohol, ether, benzene, aniline, indigo, morphia, &c. It is not found largely in nature in the free or uncombined state, but it does occur in some

Fig. 2.

other words, the cross-section and pressure increase together and diminish together. A familiar illus-

gaseous emanations from the earth, as in the solfataras of Iceland and in the petroleum regions of Pennsylvania. Being the lightest gas known, its density is often adopted as the standard of comparison for the densities of other gases. The density of atmospheric air compared with that of hydrogen as unity is nearly 14.5. As hydrogen possesses the lowest atomic weight of all the elements, its atomic weight was formerly adopted by chemists as unity, and those of the other elements were referred to it; but of recent years oxygen, with atomic weight =16, has been adopted as the standard, since this atomic weight can be determined more accurately than that of hydrogen. The atomic number of hydrogen is 1.

Although hydrogen is usually classed amongst the non-metallic elements, it is in its chemical behaviour more closely related to the metals. It combines with oxygen, at a red heat forming water, this combination being accompanied by the giving out of a great deal of heat. A jet of hydrogen burns in air or oxygen with a non-luminous flame, which is, however, sufficiently hot to heat to whiteness a fine platinum wire held in it. The behaviour of hydrogen towards chlorine is extremely interesting. The two gases can be mixed in equal volumes and preserved without combination taking place for an indefinite period if kept in the dark, but on exposure to diffused daylight combination begins, and its progress depends upon the brightness of the light and the duration of the exposure. Momentary exposure to direct sunlight causes combination to take place with explosive violence, and a similar effect is produced by raising any portion of the mixture to a red heat. Hydrogen as a rule combines with those things with which the metals in general combine, forming compounds which are analogous to those of the metals. Compounds containing hydrogen and one other element are common decomposition products of decaying vegetable and animal matters; as, for instance, marsh-gas, ammonia, and sulphuretted hydrogen, which contain hydrogen combined with carbon, nitrogen, and sulphur respectively.

The fact that an inflammable gas was evolved when dilute sulphuric or hydrochloric acid interacts with iron filings seems first to have been observed by Boyle in the middle of the 17th century; but Cavendish (q.v.) in his paper on 'Factitious Airs,' published in the *Transactions of the Royal Society* for 1766, was the first to describe accurately the properties of this gas, and the methods of obtaining it, hence he is usually mentioned as its discoverer.

The ordinary methods for preparing and purifying hydrogen will be found in any elementary treatise on chemistry. See GAS; and for sulphuretted hydrogen, see SULPHUR.

Hydrogenation. See OILS.

Hydrogen Peroxide (sym. H_2O_2) is a compound of hydrogen and oxygen, containing a larger proportion of oxygen than water, the other compound of these elements. It was discovered in 1818 by Thénard, and was by him regarded as oxidised water as it very readily decomposes, when heated, into oxygen and water. The substance, when freed from water as completely as possible, is a thick transparent liquid, of specific gravity 1.45, without colour or smell, but possessing a bitter taste. It bleaches many vegetable colours, and when applied to the tongue or skin produces a white spot and gives rise to considerable pain. Its bleaching action and most of its chemical characters depend upon its powerfully oxidising properties. It is employed, in dilute solution, for the restoration of oil-paintings, and in the preparation of cosmetics and mouth-washes.

Hydrography, as a branch of physical geography, deals with the waters of the globe. The hydrographer determines by means of observations and soundings the outline of coasts and shores, the configuration of river-beds, lake-basins, and the sea-bottom adjacent to coasts, ascertains the position and extent of shoals and rocks and islands, investigates the nature and velocity of currents, the local tidal phenomena, the changes taking place in river-mouths, and the alterations effected in coast-lines by the action of the sea. See CHART.

Hydroid. See HYDROZOA.

Hydromechanics, a term sometimes used so as to cover what in this work is dealt with at Hydrodynamics (q.v.) and Hydrostatics (q.v.), as also hydraulics, or the department of engineering which deals with the application of liquids in motion to machinery. Hydromechanics is sometimes limited to the latter department alone. On the other hand, hydraulics is sometimes made to cover hydrodynamics. See ENGINEERING, with articles there cited, and WATER, SEWAGE.

Hydromedusæ. See HYDROZOA.

Hydromel, a beverage made of honey and water; fermented, it becomes mead.

Hydrometer, an instrument which indicates, by the depth to which it sinks in a liquid in which it floats, the Specific Density (q.v.) of that liquid.

Hydromys, a genus of water-mice found in Australia, Tasmania, and New Guinea, distinguished from all other rodents by the small number (3) of molars. They are called Beaver-rats in Tasmania; are nocturnal and very shy; inhabit the banks of both fresh and salt water, and swim well, with the help of partially-webbed hind feet. The largest species is twice the size of a common rat. One species has the belly white, the other yellow.

Hydropathy. See HYDROTHERAPY.

Hydrophitis. See SEA-SNAKE.

Hydrophobia (Gr. *hydōr*, 'water,' and *phobos*, 'fear') is a symptom of a disease known as Rabies, which may occur in man and in various animals; but the word hydrophobia is also frequently used to denote the disease itself. It has long been known that rabies is communicated from one animal to another if the saliva of the one is introduced into the organism of the second; whether it be the case that the first has bit the second, or has only licked it on an open sore. The saliva of a rabid animal produces no injurious effect if brought in contact with the unbroken skin of an animal, provided it be not excoriated. In civilised countries the dog is the animal most frequently affected by rabies. In less settled regions the wolf is a frequent source of the disease.

When a rabid dog bites another animal the latter shows no immediate symptoms of disease. The wound caused by the teeth of the dog behaves like an ordinary wound and may heal. After the lapse of a certain period (called the incubation period), which may vary from nine or ten days to several months (cases are known where the time has been as long as twenty-six or twenty-eight months), but is generally from four to six weeks, the animal that was bitten exhibits the special symptoms of the disease. In man, the first symptom is usually a change of character; he becomes melancholy and distrustful. Next, generally at the beginning of the case, appears a symptom called *aërophobia*—the smallest breath of wind which touches the skin of the face causes its muscles to contract. Next comes hydrophobia—if the sufferer

is offered anything to drink, his throat contracts, and he suffers spasms of the pharynx. When this symptom appears the death of the sufferer is at hand, and is certain to occur in two or three days. During the interval between the appearance of the hydrophobic symptoms and death the patient has periods of calm and accessions of fury, and also exhibits paralytic symptoms which usually commence in the lower limbs. In some cases only these paralytic symptoms are present.

Rabies is therefore communicated by biting from one animal to another; any scratch made by the teeth of the affected animal must be treated as an infected wound. The animals liable to be affected by rabies are very numerous, and comprise almost all the mammalia—men, dogs, cats, horses, cattle, sheep, wolves, foxes, deer, &c.

The question of the etiology of rabies has remained very obscure, and the most contradictory opinions were current until M. Pasteur in 1880 set himself to study this malady. His labours justify the following statements.

Rabies is a virulent disease, transmissible from one animal to another by the inoculation into the latter of those various secretions and tissues of the affected animal in which the virus dwells. This virus consists of a living organism, the nature of which is unknown, but its existence can nevertheless not be denied.

Pasteur studied the distribution of the virus in the individuals affected. He observed that the virus was found in the nervous system and in the saliva, but not in the blood, the lymph, &c. Hence, if we inoculate another animal with the blood of a rabid beast, the first will remain wholly free of any rabid infection. Similarly, rabid virus introduced directly into the circulatory system of an animal will not produce rabies. But there is a sure means of communicating rabies from one animal to another—viz. by the introduction under the dura mater, on the surface of the brain, of a portion of the central nervous system of the rabid animal. By this operation one is absolutely certain to communicate rabies to a susceptible animal. In the course of his studies Pasteur observed that, in certain animals which had been inoculated beneath the skin with large quantities of rabid virus, some not only did not take rabies, but became incapable of taking it—i.e. they might with impunity be inoculated even on the surface of the brain with rabid virus. This observation was the origin of the discovery of preventive inoculation, by which, at will, an animal can be rendered refractory to rabies.

The principle of such inoculation is as follows: The spinal cord of a rabbit which has died of rabies, if preserved in dry air at a temperature of 23° to 24° C. (74° to 76° F.), slowly loses its virulence. With a spinal cord which has been so preserved for fourteen days it is impossible to communicate rabies to a rabbit or a dog. But this spinal cord has nevertheless still a certain power to confer immunity from the disease—the inoculation of an animal with a sufficient quantity of it will render it refractory to rabies. At the same time Pasteur observed that the freshest spinal marrows, that is to say, the most virulent, are those best fitted to confer immunity from infection. To render an animal refractory to infection the treatment commences by inoculating it with spinal cord fourteen days old, then with that of thirteen days, and so on till spinal matter three days old is reached, two days, one day, and even such as is not yet one day old. The last may be introduced into the subject of experiment without danger, because he is already refractory.

What gives this discovery an enormous value is that these preventive inoculations made on an animal (e.g. man) early enough *after* he has been

bitten prevent rabies from declaring itself. This is explicable on the following grounds: The virus is deposited by the dog's bite in a superficial wound: there it meets with little nerve-filaments in which it is further cultivated, and by means of which it ascends, somewhat slowly, to the nervous centres. These nerve-centres are the quicker affected the nearer to them the bite has been inflicted: hence bites on the head produce rabies after a shorter period of incubation than bites on the extremities of the body. If there is time to render the organism refractory by means of the preventive inoculations before the nerve-centres are affected the victim is saved. The length of the incubation period in man happily thus makes it possible by Pasteur's method to originate a protective immunity before the virus introduced in the bite has had time to affect the nervous system. In modern practice the Pasteur method has been modified and simplified by the substitution of increasing doses of a rabbit's cord of moderate virulence for doses of constant size of cords of increasing virulence.

All attempts by the ordinary methods of bacteriology having failed to isolate any organisms from the infective nervous system of rabid animals, much speculation has taken place as to the nature of the hydrophobic virus. Similar failure has attended the investigation of other undoubtedly infective diseases, e.g. smallpox, yellow fever, South African horse-sickness, foot-and-mouth disease. In all of these cases, however, if the virus be forced through a block of unglazed earthenware, the pores of which are sufficiently small to keep back all objects recognisable by the most powerful ordinary microscope (i.e. less than one-two hundred and fifty thousandth of an inch), the fluid passing through is still capable of reproducing the disease when injected into a suitable animal. That the filtrate contains a living organism capable of multiplication, and not a very powerful soluble poison (as in the case of Diphtheria, q.v.) is shown by the fact that if—taking the case of rabies, which we are considering—the brain of the infected animal be bruised up in salt solution and again filtered, the filtered fluid again produces the disease, and this procedure may be repeated indefinitely with the same results. If the first filtered virus had contained only a non-living poison this would, by the repeated passages, become so diluted that it would be incapable of producing any effect. The hypothesis at present held to account for these facts is that there exist living organisms which, *at any rate in one stage of their development*, are excessively small, and the diseases with which they are associated are said to be caused by ultra-microscopic or filterable viruses. The reservation stated is necessary in the case of hydrophobia, as in this disease there have been observed in certain cells in the brain small round objects which, according to some, are another stage in the development of the causal organism. These have been called, after the discoverer, Negri bodies; and as, whatever be their true nature, they have never been recorded in any other disease, the demonstration of their presence is at present relied on as showing that the animal has suffered from hydrophobia.

What ought to be done when any one is bitten by a mad dog is this. The wound made by the dog's teeth should be deeply cauterised as soon as possible, so that if possible the virus may be destroyed before it has begun to cultivate itself in the nervous system. Then, if the animal which inflicted the bite is mad, the victim should as quickly as possible be subjected to the Pasteur inoculation treatment. Bites on the head are more serious than bites on the limbs, inasmuch as there

is a shorter distance to be traversed ere the nerve-centres are reached, and all the more promptitude should be exercised in commencing the treatment.

How can one make sure that the biting dog is mad? Careful notes should be made regarding the condition of the dog during the previous few days. The course of the disease in this animal is somewhat as follows: The animal will change its character, will often cease to eat, will bite everything within its reach, and will sometimes show signs of paralysis, its hindquarters and its lower jaw being first attacked. In such cases the animal will inevitably die in from three to four days, or at most in eight days. A post-mortem examination will show the stomach empty of food, and containing on the contrary foreign substances such as bits of wood, stones, straw, &c. The most certain way of discovering if a dog has been mad is to introduce a portion of its medulla under the dura mater of a rabbit. The rabbit will inevitably become rabid if the dog was rabid, but this will not take place till after fifteen or eighteen days. If this procedure is adopted in the case of a dog which has bitten a man, valuable time, which ought to be taken advantage of for the treatment of the patient, is lost. What ought to be done is to kill the animal, preferably by shooting through the heart; to cut off its head, and send this packed in ice to a bacteriological laboratory in order that the brain may be examined for Negri bodies. In this way a diagnosis can be established in a few hours, and advice as to the proper treatment can be given.

When we look back on Pasteur's discoveries regarding hydrophobia in the light of the progress of knowledge since they were made, the genius of the discoverer shines out even more brilliantly than when it astonished the science of the period. Working at a time when only one disease—anthrax—had been actually proved to be due to a living organism, and dealing with a malady whose cause is even yet undetermined, he boldly plunged into the unknown, and emerged with solid facts which, if knowledge had progressed by the slow process of logical induction, might not yet have been attained. There is little wonder that at the time of Pasteur's discoveries their novelty aroused criticism, much of which has now lost its point in the light of knowledge since obtained. Several objections have, however, still to be met. One of these is concerned with whether Pasteurian inoculation has diminished the mortality after bites by rabid animals. While the mortality from this disease in untreated cases is difficult to arrive at, there is a statistical basis for stating that it amounts to 16 per cent. Now for the ten years, 1886–95, the mortality in cases treated by inoculation was 0·48 per cent. This figure has been objected to on the ground that many cases have been treated where there was no evidence that the dogs biting the patients were really mad. A perusal of any of the returns periodically published by the Pasteur Institute in Paris shows this objection to be groundless. The cases treated are classified into three groups—(1) those where, by inoculation, the biting dog has been proved to be mad; (2) those in which a qualified veterinary surgeon has pronounced the dog to be mad; (3) all other cases. To take the first group only, from 1886 to 1897, 1759 cases were treated, with a mortality of 1·1 per cent. Another objection has been raised that in certain cases inoculation of persons not bitten by mad dogs has caused infection with rabies. While such an unfortunate occurrence cannot be excluded, its rarity is to be set against the undoubted benefit which has accrued in the thousands of cases where death has been prevented by inoculation. On the whole question, the finding of a committee of experts

which reported to parliament in 1887 still represents the considered conclusion of science on the subject. That finding was expressed as follows: 'It may, hence, be deemed certain that M. Pasteur has discovered a method of protection from rabies comparable with that which vaccination affords against infection with smallpox.'

'Pasteur Institutes' for the treatment of patients have come into existence all over the world. The parent organisation is in Paris, and it is to this that British patients are usually sent, but the provision of means of treatment is now recognised as a duty of the public health service in all civilised countries. In Britain it has hitherto not been necessary to make special provision. The insular position of the country made it possible between 1895 and 1900 to stamp out rabies among dogs completely by means of efficient quarantine regulations and a rigorous muzzling order. The country was free of the disease till 1919, when it reappeared, undoubtedly in consequence of the enormous traffic with the Continent consequent on the war. There is no reason to anticipate that this recrudescence was other than a passing incident.

Hydrophyllaceæ, a natural order of sym-petalous dicotyledons, herbs and bushes, containing about 230 known species, natives chiefly of the colder parts of America. Some are favourite ornaments of flower-borders, particularly different species of *Nemophila* (q.v.). *Phacelia tanacetifolia* has been introduced in Europe as an excellent plant for agriculture; *Wigandia caracasana*, with huge leaves, is planted a good deal in southern gardens, and the species of *Hydrophyllum* furnish leaves that are eaten like spinach or salad ('Shawnee Salad' in Colorado).

Hydrophytes. See AQUATIC PLANTS, ECOLOGY.

Hydroplane, a name best reserved for a skimming boat which cannot leave the water, and sometimes given to what is better termed a 'water-plane,' a sea-going aeroplane.

Hydropteridææ. See WATER-FERNS.

Hydrostatics treats of the equilibrium of liquids, and of their pressures on the walls of vessels containing them. It is a purely dynamic science, and concerns itself virtually with only two of the many physical properties of liquids. These are density and mobility. In virtue of the latter property, a liquid has no tendency to conserve its shape, so that if a distorting force acts on it it yields without any tendency to recover. It has no Elasticity (q.v.) of form. Viscosity (q.v.) may retard the rate at which the distorting force takes effect; but a liquid will continue to change form so long as there is a force acting on it which is not balanced by a perfect reaction. Thus, in hydrostatic problems, nothing of the nature of a distorting force is taken into consideration. All pressures acting on portions of the liquid must therefore be perpendicular to the surfaces on which they act; and equilibrium requires equality of pressure in all directions at any point.

The fundamental property may be thus stated: When a pressure is exerted on any part of the boundary of a liquid at rest, that pressure is transmitted undiminished to all parts of the mass and in all directions. Most of the other propositions of hydrostatics are only different forms or direct consequences of this truth, which may be proved experimentally. Suppose a close box B to be filled with water, and to have inserted into the upper cover a tube *a*, with closely-fitting plug or piston, 1 square inch in area. If the piston *a* is now pressed down upon the water with a force equal to a pound weight, the water, being unable to escape, will react upon the piston with

the same force; but it obviously will not press more against a than against any other part of the box, therefore every square inch of the interior

Fig. 1.

surface of the box is pressed outward with the force of a pound. If, then, there is another tube inserted in any part of the box with a plug of the same area, as at b , it will require a force of a pound to keep this plug in its place. (We leave out of account at present the pressure upon b arising from the weight of the water in the box above it—i.e. we neglect gravity and consider only the pressure propagated by the forcing down of the plug a .) However many plugs of the same size there may be, each will be pressed out with the same force of a pound; and if there be a large plug of four times the area, as at c , it will be pressed out with a force of four pounds. We have only, then, to enlarge the area of the piston c to obtain any multiplication of the force exerted at a . If the area of c is 1000 square inches, that of a being 1 square inch, a pressure of one pound on a becomes a pressure of 1000 pounds on c ; and if we make the pressure on a one ton, that on c will be 1000 tons. This seemingly wonderful multiplication of power has received the name of the *hydrostatic paradox*. It is, however, nothing more than what takes place in the lever, when one pound on the long arm is made to balance 100 pounds on the short arm.

If the pressure supposed to be exerted on the piston a arise from a pound of water poured into the tube above it, it will continue the same though the piston be removed. The pound of water in the tube is then pressing with its whole weight on every square inch of the inner surface of the box—downwards, sideways, and upwards. The apparatus called the *hydrostatic bellows* acts on this principle (see fig. 2). It consists of two stout circular boards connected together by leather in the manner of a bellows, B . The tube A is connected with the interior; and a person standing on the upper board, and pouring water into the tube, may lift himself up. If the area of the upper board is 1000 times that of the tube, an ounce of water in the tube will support 1000 ounces at W . It is on the same principle that the Hydraulic Press (q.v.) depends.

Fig. 2.

(1) *Equilibrium of Liquids*.—After this explanation of the fundamental properties of liquids it may be enough to state the two conditions of fluid equilibrium which directly flow from it. (1) Every particle of the liquid must be solicited by equal and contrary pressures in every direction; otherwise there would be a tendency to motion, and therefore motion because of the liquid property of mobility. (2) The upper particles at the free liquid surface must form a surface perpendicular to the impressed force. The truth of this is experimentally demonstrated by the horizontality of the surface of a liquid at rest under gravity. It can be shown to be a consequence of the primary property of 'pressing equally in all directions,' for let da and cb be vertical lines, or lines in the direction of gravity; and ab a plane at right angles to that direction, or horizontal. A particle

of the liquid at a is pressed by the column of particles above it from a to d ; and the like is the case at b . Now, since the liquid is at rest, these pressures must be equal; for if the pressure at b , for instance, were greater than at a , there would be a flow of the water from a towards b . It follows that the line ad is equal to bc , and hence that dc is parallel to ab , and therefore horizontal. The same might be proved of any two points in the surface; therefore the whole is in the same horizontal plane.

Fig. 3.

(2) *Pressure of Liquids on Surfaces*.—The general proposition on this point may be stated thus: The pressure of a liquid on any surface immersed in it is equal to the weight of a column of the liquid whose base is the surface pressed, and whose height is the perpendicular depth of the centre of gravity of the surface below the surface of the liquid (see CENTRE OF PRESSURE). The pressure thus exerted is independent of the shape or size of the vessel or cavity containing the liquid.

(3) *Buoyancy and Flotation*.—As a consequence of the proposition regarding the pressure of liquids on surfaces it can be shown that when a solid body is immersed in a liquid its loss of weight is equal to the weight of the displaced liquid—i.e. to the weight of an equal bulk of liquid. Thus, if a cubic foot of the liquid weighs the same as a cubic foot of the solid, the solid will appear to have lost all its weight, and will remain in the liquid wherever it is put; if a cubic foot of the liquid weighs less than a cubic foot of the solid, the solid will appear to lose part of its weight, and will sink; but if a cubic foot of the liquid weighs more than a cubic foot of the solid, the immersed solid will not only lose all its weight, but will appear to be dominated by a *negative* weight, being urged upwards to the surface of the liquid by a force equal to the difference of the weights of the displaced liquid and the solid. In this last case the solid will rise until it swims or floats on the surface of the liquid, the amount of solid immersed in this final state of equilibrium being determined by the obvious principle that a floating body must be buoyed up by a force equal to its own weight. Here again, then, the solid seems to lose all its weight, which loss must be simply the weight of the displaced water.

Fig. 4.

Thus in fig. 4, where AB represents a floating solid, the water displaced by the immersed part B is equal in weight to the whole solid.

As the buoyancy of a body thus depends on the relation between its weight and the weight of an equal bulk of the liquid, the same body will be more or less buoyant, according to the density of the liquid in which it is immersed. A piece of wood that sinks a foot in water may sink barely an inch in mercury. Mercury buoys up even lead. Also a body which would sink of itself is buoyed up by attaching to it a lighter body; the bulk is thus increased without proportionally increasing the weight. This is the principle of life-preservers of all kinds. The heaviest substances may be made to float by shaping them so as to make them displace a volume of water greater than the bulk of their own solid substance immersed. A flat plate of iron sinks; the same plate, made concave like a cup or boat, floats. It may be noted that the buoyant property of liquids is independent of

their depth or expanse, if there be only enough to surround the object. A few pounds of water might be made to bear up a body of a ton weight; a ship floats as high in a small dock as in the ocean.

(4) *Stability of Floating Bodies.*—Conceive *abd* (fig. 5) to be a portion of a liquid turned solid,

Fig. 5.

but unchanged in bulk; it will evidently remain at rest, as if it were still liquid. Its weight may be represented by the force *cg*, acting through its centre of gravity *c*; but that force is balanced by the upward pressure of the water on the different parts of the under surface; therefore, the resultant of all these elementary pressures must be a force, *cs*, exactly equal and opposite to *cg*, and acting through the same point *c*, otherwise the body would not be at rest. Now, whatever other body of the same size and shape we suppose substituted for the mass of solid water *abd*, the supporting pressure or buoyancy of the water around it must be the same; hence we conclude that when a body is immersed in a liquid the buoyant pressure is a force equal to the weight of the liquid displaced, and acting in the vertical line through the centre of gravity of the space from which the liquid is displaced. This point may be called the *centre of buoyancy*.

We may suppose that the space *abd* is occupied by the immersed part of a floating body *aebd* (fig. 5). The supporting force, *cb*, is still the same as in the former case, and acts through *c*, the centre of gravity of the displaced water; the weight of the body must also be the same; but its point of application is now *c'*, the centre of gravity of the whole body. When the body is floating at rest or in a state of equilibrium, this point must evidently be in the same vertical line with *c*; for if the two forces were in the position of *cs*, *c'g* (fig. 6), they would tend to make the body roll over. The line passing through the centre of gravity of a floating body and the centre of gravity of the displaced water is called the *axis of flotation*.

A floating body is said to be in *stable equilibrium* when, on suffering a slight displacement, it tends to regain its original position. The conditions of stability will be understood from the accompanying figures. Fig. 7 represents a body

Fig. 7.

Fig. 8.

floating in equilibrium, *G* being its centre of gravity, *B* its centre of buoyancy, and *AGB* the

axis of flotation, which is of course vertical. In fig. 8 the same body is represented as pushed or drawn slightly from the perpendicular. The shape of the immersed portion being now altered, the centre of buoyancy is no longer in the axis of figure, but to one side, as at *B*. Now, it is evident, that if the line of direction of the upward pressure—i.e. a vertical line through *B*—meets the axis above the centre of gravity, as at *M*, the tendency of the two forces is to bring the axis into its original position, and in that case the equilibrium of the body is stable. But if *BM* meet the axis below *G*, the tendency is to bring the axis further and further from the vertical, until the body get into some new position of equilibrium. There is still another case; the line of support or buoyancy may meet the axis in *G*, and then the two forces counteract one another, and the body remains in any position in which it is put; the body is then said to be in *neutral equilibrium*. In a floating cylinder of wood, for instance, *B* is always right under *G*, in whatever way the cylinder is turned. When the angles through which a floating body is made to roll are small the point *M* is nearly constant. It is called the *metacentre*; and its position may be calculated for a body of given weight and dimensions. In the construction and lading of ships it is an object to have the centre of gravity as low as possible, in order that it may be always below the metacentre. With this view, heavy materials, in the shape of ballast, are placed in the bottom, and the heaviest portions of the cargo are stowed low in the hold.

Hydrotherapy, or **HYDROTHERAPEUTICS**, is the system of treating disease by means of the various water applications which are almost inseparably associated with thermotherapy under the joint description, balneology. The word hydrotherapy is a popular one used almost exclusively by the laity. The term hydrotherapy is applied to the use of plain water as distinguished from the external or internal administration of the medicinal waters found at various spas. The water is not used for the reason that it contains any saline ingredients of therapeutic value, but merely because it is what is termed a very *flexible* medium for applying heat and cold. Needless to say, water is a very ancient remedy. Hippocrates most of all was a great believer in its virtues, as well as Galen, Celsus, Asclepiades, and others. In the middle ages Paulus of Aegina and Alexander of Tralles were exponents of its uses. Dr James Currie of Liverpool was the first to use cold water to any extent in fevers. Currie carried out a series of experiments, and published a treatise on his findings (*Medical Reports*, 1798), which was translated into German, and led to much comment and controversy. Water treatment has ever been one of the battle-grounds of medicine, and this has often been due to prejudice aroused by the fact that many of the pioneers were laymen who made up in enthusiasm, sometimes misdirected, for their lack of anatomical and physiological knowledge. Prominent among these was Vincenz Priessnitz, a Silesian farmer, who at Gräfenberg in the first few years of the 19th century made a big stir by his enthusiastic use of water, chiefly cold, for all manner of ills, surgical and medical. He started his work on animals, and then, having sustained an injury to his chest, involving fracture of one or more ribs, he made use of water applications, accelerating, in his own opinion at any rate, his cure. He soon acquired a large *clientèle*, first among his neighbours and fellow-farmers, but afterwards among all classes of society, including the nobility and church dignitaries. Making all allowance for the exaggeration of enthusiastic patients, the novelty of the remedy, and the flight of time, one cannot but conclude

that he met with considerable success, and must have been a man of parts and much ingenuity. Doubtless it was not all due to the external use of water, but rather to its substitution for strong drink, so much abused at that period, and to the ordering of a rigidly plain dietary and plenty of walking exercise for people who were as a rule idle and self-indulgent. His ignorance of ordinary medical lore was about as complete as it could be even in those days, but the experience of handling many invalids, real or imaginary, seems to have enabled him to build up rough working hypotheses and a pathological theory of the humoral type. He came to the conclusion that the blood in disease got full of some abnormal constituent which he believed to be acid, and the way to get rid of it was to wash the patient or douche him freely, make him drink much water, and even blister him with continuous applications of wet compresses. This last was what is known as the *crisis* treatment. It was employed at Matlock until well on in the 1890's. It was certainly a form of counter-irritation, but the rash or eczema produced was probably due to germ infection in a moist warm medium, causing a dermatitis locally—that is, an inflammation of the skin which might even suppurate. The pus, if it appeared, Priessnitz looked upon as 'bad humour,' and the case would be considered a severe one. The theory was quite unsound, the treatment painful, and to be condemned.

Captain Claridge, one of Priessnitz's 'cures,' was practically the pioneer of the cold-water treatment in England. He was a gentleman of good family, hailing from Warwickshire, and a martyr to rheumatism. It was with considerable diffidence, while travelling on the Continent, that he entrusted himself to the drastic treatment of Priessnitz. But the result was so remarkable in his case that he expressed the opinion that 'Priessnitz must be acting under divine inspiration.' How drastic it was may be judged by the following daily timetable: A blanket-pack lasting an hour at 4 A.M., leading to profuse perspiration which was encouraged in every possible way, followed by a three-minute cold plunge-bath. Breakfast of milk, bread, and fruit followed. At 10 A.M. a cold douche of four minutes was given, followed by foot and sitz baths; at 4 P.M. another cold douche; more foot and sitz baths; and bed at 9.30 with legs swathed in cold-water bandages. In three months walks amounting to 1000 miles were taken. Returning to England, Claridge published his book, which attracted great attention, and a host of lay and medical imitators of Priessnitz sprang up, who squabbled with one another on technical points, threw much abuse at the medical profession, then chiefly engaged in administering large doses of calomel and bleeding, who in turn roundly abused and decried the water-curers as cranks and fanatics.

Out of the bigotry and turmoil of these years good has undoubtedly materialised, and our modern hydrotherapy became established as a valuable means of treating disease. Hydrotherapy was popularised in England about 1842 by the treatise of Dr Gully of Malvern; and it was placed on a reliable working basis largely through the efforts of Ernst Brand of Stettin (1827-97) and of Wilhelm Winternitz of Vienna (1835-1905), who wrote a well-known modern treatise on the subject. This method of treatment is now extended to the reduction of high temperature in fevers, the quieting of mental excitement in insanity, the relief of pain in rheumatism, and many other conditions. Hydrotherapy at the present day includes not only the use of baths at various temperatures, but numerous forms of douche and spray, hot and cold, and of 'packs,' in which the patient lies wrapped in a

sheet or blanket wrung out of hot or cold water. Peat, mud, and other solids are often added to the water; and massage and gymnastic exercises enter very largely into combination with the hydrotherapeutic measures. Further, the use of hot water has to some extent been displaced by various forms of electric and hot-air apparatus, which effect the treatment by dry heat.

The various technical descriptions of water applications are to be found under BATHS.

Hydrothorax (derived from *hydōr*, 'water,' and *thōrax*, 'the chest') is the term applied to dropsical collections in the pleura. See DROPSY, PLEURISY.

Hydrozoa, a class of Cœlentera, or Stinging Animals, including zoophytes or hydroid colonies, medusoids, or swimming-bells, and Siphonophores, like the Portuguese Man-of-War (*Physalia*). Some authorities include the true jelly-fishes, or Scyphomedusæ, along with the Hydrozoa, and they use the term Hydro-medusæ with the same connotation as is given in this article to Hydrozoa. The class exhibits two types of animal form, reducible to a common plan, namely, the cylindrical sedentary polypoid type, and the free-swimming medusoid type; and these are often combined in one life-

a, *Syncoryne frutescens* (reduced); b, branch of same (magnified); c, *Sarsia*, Medusa of same, shortly after liberation. (After Allman.)

history—a phenomenon known as Alternation of Generations (q.v.). In these cases, an asexual vegetative hydroid colony buds off sexual free-swimming medusoids, which produce eggs and sperms; and the fertilised ova develop into free-swimming larvæ, which settle down as polyps and produce a colony by budding. The Hydrozoon polyp differs greatly from the Anthozoon polyp—e.g. of sea-anemone and dead-men's fingers—e.g. in the absence of an inturned ectodermic gullet, and of internal partitions or mesenteries. The Hydrozoon Medusoid differs greatly from the Scyphozoon Medusa—e.g. in the absence of a velum around the margin, of an inturned ectodermic gullet, and of special digestive filaments. The chief divisions of the Hydrozoa are: (a) the Tubularian, Campanularian, Sertularian, Plumularian, and other zoophytes, many of which have their associated medusoids (Anthomedusæ and Leptomedusæ); (b) the very calcareous Millipore 'corals' or Hydrocorallinae, some of which bud off medusoids; (c) the permanent medusoids (Trachymedusæ), which produce medusoids again, and are often like miniature jelly-fishes; and (d) the free-swimming Siphonophora—colonies of modified medusoid and polypoid individuals. It is probable that the extinct Graptolites were Hydrozoa.

See Allman, *Monograph of Gymnoblasic Hydroids* (Ray Society, 1871-72); Hincks, *British Hydroid Zoophytes* (1868); Hickson, 'Cœlentera' (*Cambridge Natural History*, vol. i. 1906); Fowler, 'Hydrozoa' (*Lankester's Treatise on Zoology*, 1900); and the articles CORAL, HYDRA, JELLY-FISH, POLYP.

Hyères, a town of Provence, in the French department of Var, on a southern hill-slope, crowned by a ruined castle, 3 miles from the

Mediterranean, and 11 E. of Toulon. Embosomed in palm-groves and orange-orchards, it is celebrated for the beauty of its situation and its mild, dry climate, and has therefore grown in favour as an invalid resort between October and May. An English church was built in 1884; and since 1875 great improvements have been carried out in drainage, water-works, boulevards, &c. Massillon was a native. Pop. 17,500. Near the coast lie the wooded Iles d'Hyères or d'Or (anc. *Stæchades*). Here the heat of the climate is tempered by the sea-breezes, and the season seems an eternal spring.

Hyetography. See RAIN.

Hygieia, in classical mythology the goddess of Health, was the daughter of Asklepios (*Æsculapius*). She was worshipped at Athens, Corinth, Argos, and other important cities, and in works of art is usually represented as a virgin with a snake, the symbol of health, which drinks from a cup held in her hand.

Hygiene is a general name for the study of the conditions and methods of promoting health and of preventing disease. Broadly, the term is now synonymous with preventive medicine. It deals not only with the health effects of weather, climate, air, soil, water, foods, beverages, clothing, exercise, occupations, housing, overcrowding, accumulations of refuse, and the like, but also with the wide field of directly preventable diseases: the infectious diseases, the diseases incident to special trades—e.g. dust diseases, chronic arsenical or phosphorus poisoning, lead poisoning, and others.

To fulfil the two objects of the promotion of health and the prevention of disease it has been found necessary, in the course of social evolution, to create elaborate public health statutes regulating practically every phase of the communal life, from the selection of a house site to the medical treatment of individual persons. This evolution is the primary difference between the ancient world and the modern. In Greece and in Rome, civic organisation compelled attention to certain primary conditions of health in the city—namely, water-supplies and protection from the effects of accumulations of human filth, the sanitation of camps, and, on the positive side, promotion of athletic training. The place given to athletic training in Greece remains an inspiration to the modern world. In Rome, much attention was given to sewerage and water-supply. The Cloaca Maxima, though primitive in structure, and the water aqueducts across the Campagna, survive in part to this day as evidence of the Roman appreciation of at least two cardinal conditions of communal health. But in the ancient world there is little to show that the civic energies were definitely and systematically applied to the prevention of disease. No doubt the magnificent baths of Rome were a great factor in the individual health of the citizens; but neither in Greece nor in Rome was there any serious science devoted to the prevention, by drainage or otherwise, of diseases like malaria. Indeed, it has been maintained that one chief factor in the decay of ancient Greece was the deterioration induced by malaria in the successive generations of people. Through the middle ages, pandemics of typhus and plague, not to speak of cholera, compelled European countries to some efforts at prevention; but, naturally, in the absence of effective science, those efforts remained unfruitful. In studying a book like Hirsch's *Geographical and Historical Pathology*, one is saddened with the weary story of failure after failure to master the great epidemics. But, apart from a few systematic efforts at prevention of infection, public health in the modern sense, that is, a systematised common effort first to study the nature of disease and then

to prevent it, may fairly be regarded as the work of the 19th century. In the late Dr J. B. Russell's *Evolution of the Public Health Function in Glasgow* it is shown how, from one insane panic to another, the city finally set itself towards the middle of the century to improve its water-supply, to eradicate its filthy slums, to prevent typhus by attending to sanitation in the inter-epidemic periods, to dissociate the infections both from general disease and from one another, to provide adequate isolation hospitals, to attend to the food-supply, to wage steady war on overcrowding, and to consider the fundamental problem of the re-housing of the people.

Almost every large city repeats Glasgow's history. But we may now say that the medical schools, the municipalities, the county governing authorities, the education authorities, and the general public have become conscious of the fact that, to prevent disease and to promote health, highly elaborated and specialised administration is essential. This lesson the Great War drove home even on the business world. The careful reports issued by the Committee on the Health of Munition Workers show to what an enormous extent output can be guided and increased by detailed attention to the health conditions of the factories and the personal health of the workers. These reports of the greatest industrial experiment in history confirm all the contentions of the pleaders for greater control of industrial hygiene, which already is very minutely regulated. Supplementary facts even more striking are to be found in the report by the Ministry of National Service on the physical examination of men of military age by the national service medical boards. The one report shows how, by careful attention to the welfare of the workers—their hours of labour, their food, their fatigue, their housing—the standard of health and output may be kept up; the other report shows how, under the present conditions of industry, the unfitness of individuals may be such as to justify the following statement: 'The presence of such dwarfed and ill-developed creatures can be attributed only to the conditions of life created by our industrial development, and reckoned without fear of contradiction as eminently calculated to cause racial deterioration and to give every opportunity to the ravages of disease.' This serious deliverance by a body of skilled medical men rests on returns of examination and re-examination of at least 2,400,000 men conducted in the period from November 1917 to October 1918. The details of this gigantic medical inspection constitute a very serious comment on the inadequacy of the present methods of preventive and curative medicine. Other countries show similar figures. But our own facts show how far this country must travel before we can realise the best conditions for promoting health and preventing disease.

Let us now give a few illustrations of the methods of hygiene or preventive medicine.

Meteorology and Climate.—Climate determines, to a certain extent, the incidence of disease. In warm climates the prevailing communicable diseases are such as these: malaria, dysentery, cholera, enteric fever, yellow fever, plague; the other diseases include heat apoplexy and the like. But all diseases are modified in very warm climates. Conversely, the communicable diseases are less common in cold climates, say those between 55° latitude and the poles. The greatest relative freedom from diseases is found in temperate climates, say those ranging from 35° to 55° of latitude. Yellow fever is a typical illustration of diseases that cannot live except in warm climates. The centres where it occurs lie between 40° N. and 40° S. latitude, where 'the main isotherm is not below 26° C. (78·8° F.).' But the disease may go

beyond this limit in the hot seasons. It also illustrates another important point—namely, the work of insects in spreading disease. A certain mosquito (*Stegomyia fasciata*) sucks the blood of a yellow fever patient, say, within the first three days of sickness; if, after about twelve days, but not earlier, this mosquito bites another person, it may convey the disease. Apparently, this is now recognised as the sole method by which yellow fever is spread. In the making of the Panamá Canal the chief obstacle was yellow fever. Acting on the knowledge that the disease was spread by a special mosquito, the American medical service instituted anti-mosquito campaigns all over the zone, and, as a result, 'the number of cases of yellow fever was reduced so rapidly that within five years the disease had completely disappeared from this region.' Similar methods are now applied for the prevention of malaria, sleeping sickness, and other tropical diseases.

Climate has long been exploited in the treatment of disease, particularly tuberculosis. Recent investigations show that the value of climate as a factor in treatment depends, like the value of open air and ventilation generally, on the relation between the heat production in the body and the cooling power of the surrounding medium. It is on this relationship that the effects of climate on fundamental metabolism primarily depend. By careful selection of locality, a patient may find a suitable climate without necessarily leaving the British Islands. But, no doubt, many diseases are favourably affected by residence in dry climates like certain parts of Egypt, or high altitudes like certain areas of Switzerland. As affecting the whole communities, the use of a change of climate is necessarily restricted.

Water-supply.—Centuries of study have shown that, on the large scale, water-supplies can be made safe by special forms of treatment. In earlier days great epidemics of typhoid fever and other intestinal troubles sprang from impure water. One of the greatest strides in sanitation was taken when the great cities decided to go to the unpolluted lochs and rivers for their water. With rare exceptions, all the large cities of Britain are now provided from reasonably clean rivers; but in many cases still, the water is taken from rivers polluted by the sewage of cities and rural areas. But by scientific, slow filtration with sand, ninety to a hundred per cent. of infective bacteria can be removed. Where filtration on the large scale is difficult, water may be treated by the addition of excess lime, or may be chlorinated by small quantities of hypochlorite of lime. In both cases the result is practically sterilisation. The defect of chlorination is that it tends to spoil the taste of the water. It is now accepted that the best water-supply is water from an upland unpolluted source, stored for a period of, say, one month, and filtered. By storage and filtration alone it is possible practically to sterilise a water-supply. Wherever the water-supplies have been improved, enteric fever and certain forms of diarrhoea have tended to disappear. Further, a plentiful water-supply facilitates the introduction of water into houses, and thereby promotes better conditions for the removal of all forms of house waste. Accordingly, both for personal and communal health, a copious water-supply is essential. See WATER.

Removal of Waste and Refuse, &c.—Adequate means for the removal and treatment of sewage are as essential as a good water-supply. Sewerage is now a great engineering problem, with a technique of its own. So is the treatment of sewage. On this group of problems a royal commission sat for many years, and experimented with all known methods. Here they were faced with the problems,

not merely of house sewage, bath wastes, &c., but also with the problems of trade wastes and their purification. Many good fishing rivers have been more or less spoiled by pollution with trade wastes. The methods of improvement are a constant study of the experts. Other primary necessities are: systematic removal of house refuse, systematic cleansing of streets, lighting, spacing of houses to secure circulation of air. In the large cities, as well as in the special lighting and scavenging districts of counties, all these problems involve considerable outlay and service. But it is found universally that where those conditions are neglected the health of a city, as shown by death-rates or disease-rates, suffers.

Specialised Sanitation.—In the industrial cities sanitation to be effective must be highly specialised. The nuisance sections of the Public Health Acts provide for the control of nuisances arising from any foul pool, ditch, gutter, water-course, sink, cistern, water-closet, earth-closet, urinal, cesspool, drains, dung-pits or ash-pits, wells, stables, byres or other buildings for keeping animals, accumulations of refuse, manufactures or business injurious to the health of the neighbourhood, overcrowded houses, unclean schoolhouses or factories or workshops, fireplaces or furnaces that do not, as far as practicable, consume their own smoke, crowded or badly conducted churchyards or cemeteries, and endless varieties of similar conditions. The keeping of a city or a small town or a village or private houses free from nuisance is one of the first duties of a local health authority. But, in the course of administration, many of these conditions are found to involve highly technical processes. Thus the offensive trades include the business of blood-boiler, bone-boiler, manure manufacturer, soap-boiler, tallow-melter, knacker, tanner, tripe-boiler, gut or tripe cleaner, skinner or hide factor, slaughterer of cattle or horses, or any other business declared, by the local authority under special order, to be an offensive business. All these processes may require specialised machinery. Accordingly, the prevention of nuisances from them may mean great outlay, or even the arrest of a local trade. Here sanitation passes into engineering. All these trades can be conducted inoffensively when modern machinery is provided; but, apart from offensiveness, there is no danger to life. With many other trades it is different, as the manufacture of lead and its compounds, manufacture of arsenic, phosphorus, india-rubber, ganister-crushing, which is associated with chronic inflammation of the bronchi and lungs, steel-grinding, wool-sorting. In these, serious direct danger to the individual life can be prevented only by the most stringent application of hygienic regulations. Under the industrial hygiene section of the Home Office preventive codes have been elaborated for all the specialised trades; for the enforcement of a proper standard of humidity, removal of dust, special treatment of infected hair and wool to prevent anthrax, &c. These regulations are based on very extended observation and experiment. They are being constantly modified as experience directs.

As already indicated, modern hygiene aims at securing not merely the establishment of hygienic factories and workshops, but also special supervision of the welfare of the individual workers. In the manufacture of explosives, as well as in the preparation of certain portions of aeroplanes, frequent illnesses, and even deaths, were assignable to the materials used, and detailed preventive supervision was indispensable. The methods devised under stress of war-production showed the way to improvement of ordinary peace-production, particularly in the regulation of hours of labour by definite study of physiological fatigue. It is along these lines that the hygiene of factories and workshops will now develop.

In this sequence we have passed from the general hygiene of the environment to personal hygiene; from maintenance of healthy conditions to personal applications of preventive medicine. This is the predominant note of the time. Social efficiency for industrial work, or scientific investigation, or the higher learning, depends directly and indirectly on the maintenance of a high standard of individual health. This is recognised in all recent health legislation. In detail, it is implied in the partial reorganisation of medical services achieved under the National Health Insurance Acts. In the more recent proposals for placing medical institutions within easier reach of all sections of the community, in the expansions of medical service to include maternity, child welfare, medical inspection and treatment of school children, it is clearly implied that the care of the individual health must be a first charge on the communal services. This is still far from realisation, but we may give one or two illustrations of the evolutionary drift.

Prevention of Infectious Disease.—Not long ago public health enactments were restricted in practice to such diseases as constituted a direct menace to the life or health of others—namely, infectious diseases. This was natural in communities that had only begun to understand or to master even the major infections. To-day, this conception of public health is entirely superseded. The acts apply to all infections where the infected person is a danger; but also to infectious diseases like tuberculosis, or pneumonia, or malaria, where the direct infectivity of the individual may sink to zero. But the communal treatment of disease was never really limited to infectious diseases; for, under the poor-law medical service, all forms of sickness among the destitute poor have, in England since 1834, in Scotland since 1845, been treated at the public expense. Further, the Public Health Acts really include endemic as well as infectious disease, and, under special powers, such endemic diseases may be controlled, whether infectious or not. Once more, under the steady social pressure for increased institutional treatment, as well as under the powers enabling the community to provide hospitals for expectant and nursing mothers and children requiring hospital treatment, the whole conception of individual infectivity as the groundwork to common action has been departed from. The public mind is now definitely set towards providing, in ways appropriate to the various communities, such medical service, domiciliary or institutional, as each variety of disease and disablement may require. Consequently, we are rapidly passing away from the older basis of public health service and on to a new basis, where preventive medicine will be extended to cover all medical service required either to prevent the onset of disease, or, as far as practicable, to cure it when it comes.

Meanwhile, the health authorities are under obligation to provide for the prevention and treatment of the following infectious diseases among others: smallpox, cholera, plague, typhus fever, typhoid fever, diphtheria, erysipelas, scarlet fever, measles, whooping-cough, chicken-pox, mumps, relapsing fever, continued fever, puerperal fever, cerebro-spinal meningitis, epidemic polio-myelitis, malaria, dysentery, epidemic diarrhoea, tuberculosis in all its forms, venereal diseases, pneumonia in some of its forms. Encephalitis lethargica (sleepy, not sleeping, sickness) has recently appeared in Britain in considerable numbers. It is very prolonged in its course and serious in its effects; and so far, although it is known to be communicable, its germ is unknown and its treatment is empirical. They have power to require that these diseases shall be notified to the medical officer of health, although venereal diseases have never

been thus notified; to provide hospitals, reception houses, and convalescent homes; to carry out the disinfection of houses, bedding, personal clothing, and all other sources of possible infection; to deal with infected milk-supplies, infected water, infected food; to deal with contacts exposed to infection, and, in Scotland, with 'carriers'; to control ships, tents, or vans, common lodging-houses, public conveyances, dairies and milk-shops, and, generally, all occupations and premises involved in or affected by epidemic disease. Further, there are special powers for the international control of the major infections, like plague, cholera, and yellow fever, as well as for the more common infections, like smallpox, malaria, dysentery, and certain other serious infections.

Isolation hospitals in Britain are usually built on the pavilion system, each infection being assigned to a special pavilion. Sanatoria for tuberculosis are constructed to provide treatment in the open air, and suitable occupational or vocational training for patients that are capable of it. There is as yet little hospital or convalescent home accommodation for the chief infantile scourges, measles and whooping-cough, which kill thousands of young children every year or two. Thus, in Scotland alone, during the five years ending in 1915, measles killed a total of 7367 children under five. Of the dead, 2127 were children under one. In the same period, whooping-cough killed 9434 children under five, 4410 of these being under one. Together, these two diseases killed in five years 16,800 children under five.

Acceleration of intercourse among large cities, and between town and country, not to speak of the continents, has created innumerable greater opportunities for the spread of infection. A derivative result is the increased aggregation of people in cities. Consequently, the amount of infection forced upon the communities of the modern world has been much greater than in the days before steam. Yet it may be said that the great infections—plague, cholera, and smallpox—are under effective control, both domestically and internationally. The steady attack on the other major infections has resulted, broadly, in a reduction of the death-rates from most of them; in others, the total numbers have not been seriously affected by all the methods as yet tried. Typhus fever has almost vanished; typhoid fever is becoming rarer every year; scarlet fever, though not rapidly diminishing in numbers, has grown milder; but diphtheria, whose death-rate has gone rapidly down, tends to increase in numbers. If, on the one hand, we contemplate the enormous increase in the chances of infection, and, on the other, the control of plague, typhus, and smallpox, we cannot but admit that there is a great difference between 1665, the Great Plague year, and the present time, when, with occasions multiplied a millionfold, plague gives us little concern. There still remains tuberculosis, for which the systematic communal provision is in course of elaboration. It is now our greatest single scourge; it presents enormous difficulties; but the attack on it is proceeding from many sides, and, with the improvement in the general conditions of life, it tends to recede.

Provision for Mothers and Children.—Partly from a generation's study of infant mortality, partly from the impulse of general evolution towards greater care of the individual life, partly from the revelations during the Great War, there arose a movement for superintending the health of mothers and children. In 1901, for every 1000 children born in England and Wales there died 151. In 1918, the rate fell to 97. The rate 97 per 1000 is reckoned low; but it means that, in 1918, 64,386 children under one year died—that is, about

10 per cent. of the total deaths in the community. In the last eighteen years of the 19th century infant mortality 'increased a little as the result of a wave of heavy diarrhoea mortality towards the close of the century.' There was little or no tendency for the mortality from other causes to fall. But, during the first sixteen years of the present century, 'a remarkable fall occurred in the mortality both from diarrhoea and from other causes.' The rapidity of the decline has not been equal in every section of the first year of life. The fall in the first three months is relatively less than at higher ages. In 1918, the mortality of the first three months amounted to 55 per cent. of the whole for the first twelve months of life. As to the deaths of mothers, the truth is difficult to ascertain; because, even if the returns are accepted as correct, the deaths directly assigned to pregnancy or child-birth are not a sufficient index of the stresses of child-bearing. But in England and Wales for 1918, 2509 deaths were assigned to pregnancy or child-birth, a rate of 3.79 per 1000 births, or, more accurately, 3.55. If the deaths 'caused by or associated with pregnancy and child-birth' are added, this figure would be doubled, the rate being about 7.6 per 1000 births. But the deaths and death-rates are a poor index of the complications of the problem. Here housing is a factor of immense importance. In the stresses of our modern industrial communities the mothers and children tend to suffer most. In the Notification of Births Acts, 1907 and 1915, the local authorities have a powerful instrument for good: they are authorised to make such arrangements as they see fit for attending to the health of expectant mothers, nursing mothers, and children under five. Both in England and Scotland these powers have been extensively exercised, and, in all the large communities, provision is made for providing assistance during confinement, for hospital treatment in complicated cases, for providing maternity homes, maternity hospitals, out-door nursing, prenatal consultation centres, child welfare centres, treatment centres for children up to five years, hospitals, convalescent homes, play centres, boarding out, and several other activities. Under these schemes health visitors have been appointed, both to visit homes and to attend at centres and, generally, to develop the resources of the schemes.

Medical Inspection and Treatment of School Children.—Historically, the medical inspection of school children was established before the services for maternity and child welfare. Medical inspection arose directly out of the recommendations made in 1903 by the Royal Commission on Physical Training (Scotland). It was adopted first in England, and it was made obligatory in Scotland by the Education (Scotland) Act, 1908. The treatment of school children is less advanced, partly because the legislative powers came later than the powers for inspection, partly because the Great War intervened. Personal and school hygiene is taught at the training centres. There are colleges in England and Scotland for two-year diploma courses in physical education. The College of Hygiene at Dunfermline, established and managed by the Dunfermline Carnegie Trust, is presided over by a medical man as principal; anatomy, physiology, and hygiene are taught by medical teachers; the technical work of physical education is conducted by specialists in modern methods of physical training and remedial gymnastics. The system of medical inspection and treatment of school children is thus supplemented and completed by specialised education of teachers in training and by the organisation of an adequate system of physical education. The whole work of the medical inspection and treatment of school children in Scotland under the

direction of the Scottish Board of Health; in England it is under the English Ministry of Health; in both countries, these central health authorities work in concert with the Scottish Education Department and the English Board of Education respectively. The details of the work are to be found in the annual Blue-books of those authorities.

Medical Research.—From this sketch it is easily seen that innumerable problems for research emerge in the course of administration. In 1911, under the National Health Insurance Act, a fund was established for medical research, and the Medical Research Committee was formed, now called the Medical Research Council, which is under the control of the Privy Council. Through it the research of the medical schools is correlated and stimulated. Now that medical research is recognised as a national duty and established on a national footing, the whole field of general and personal hygiene is being subjected to experimental reinvestigation, and many baffling problems in preventive medicine have a chance of being solved.

Administrative Health Machinery.—In Scotland the Board of Health, and in England the Ministry of Health, are now the central authorities for poor-law, public health, housing and town-planning, national health insurance, maternity and child welfare service, medical inspection and treatment of school children, and several minor divisions of medical administration. For the local administration of the Public Health Acts there are, in Scotland, the town councils for the towns, the county councils and district committees for the counties; in England, there are the councils of the county boroughs, the county councils, and the urban and rural district councils. For the administration of medical inspection and treatment of school children there are, in both countries, the local education authorities. For poor-law there are, in Scotland, the parish councils; in England, the boards of guardians. For national insurance there are, in both countries, the insurance committees. In recent years there has been a rising demand for a state medical service. Such a service the above sketch shows to be already in existence for many sections of medical work. There are many possible lines of development now receiving the consideration of the government departments.

Conclusion.—It is now clear that the aim of modern hygiene is, by careful superintendence of the environment, to reduce the external stresses on the individual life; by education in personal hygiene, to economise the energies and to increase the efficiency of the person; by correlation of private and public services, to secure to each member of the community, at the earliest moment, the medical treatment he requires.

Hygrometer (Gr. *hygros*, 'moist,' *metron*, 'measure'), an instrument for measuring the quantity of moisture in the atmosphere. The earlier forms of hygrometer depended upon the property possessed by some substances of readily absorbing moisture from the air, and being thereby changed in dimensions or in weight. Of this kind was the hair hygrometer of Saussure, in which a hair, which expands and contracts in length according as the air is more or less moist, was made to move an index; a similar instrument was the whalebone hygrometer of Deluc; but as other causes as well as moisture affect such instruments they afford no accurate indications. The most perfect hygrometer, theoretically, is that of J. F. Daniell (q.v.). It consists of two bulbs connected by a bent tube, as represented in the figure, and enclosing a thermometer, together with some ether and vapour of ether, the air having been expelled. The bulb *b* is covered with muslin, and *a* is either blackened or coated with metal. The observer's hand is placed for a short time on *b*, to drive the ether into *a*, leaving *b* and the tube filled with vapour of ether. A little ether is then dropped from a flask, of the form *c*, on the muslin-covered bulb; evaporation instantly takes place and produces

a cooling of *b*, which condenses the vapour inside; a fresh evaporation from *a* fills the vacuum, which is again condensed by dropping ether on *b*, and the process is repeated till the temperature of *a* is so reduced by successive evaporations (see EVAPORATION) that dew begins to be formed on the outside of the bulb. At the instant this occurs the height of the mercury in the two thermometers is accurately noted, the one giving the dew-point temperature, and the other the temperature of the air. The actual quantity of moisture contained in a cubic foot of air can now be readily found from the following empirical formula: weight of moisture in

grains = $\frac{5656 \cdot 2}{448 + t} \times p$; where *t* is the temperature of the air at the time of observation, and *p* (found from tables) the elasticity of vapour at the temperature of the dew-point. The evident defects of this instrument are, first, its rapidity of operation, so that no time is allowed for the glass, ether, and thermometer to come to the same temperature, and in consequence the dew-point is given higher than it actually is; secondly, its costliness, owing to the great consumption of ether; and, thirdly, its uselessness in tropical countries, owing to the difficulty of preserving the ether in a fluid state. Daniell's hygrometer was used at the Royal Observatory, Greenwich, from 1840—the commencement of meteorological observations—till 1847, when it was superseded by the more convenient instrument, the Wet and Dry Bulb Thermometers. This instrument consists of two ordinary thermometers: one has its bulb bare, and thus shows the temperature of the air; the other has its bulb covered with muslin, which is kept wet by a cotton wick dipping into water. The evaporation from the muslin, and consequent cooling of the bulb, being in proportion to the dryness of the air, the difference between the readings of the two thermometers is greatest when the air is driest, and zero when it is completely

saturated. The extent to which the temperature of the wet bulb is lowered below that of the dry depends on the manner in which the instrument is ventilated. Thus on a calm day, by fanning the wet bulb its temperature may be lowered by a degree or more. The necessity of getting reliable observations under the conditions that prevail in balloon ascents led to the invention by Dr Assmann of the ventilated or aspiration psychrometer. This instrument consists essentially of dry and wet bulb thermometers mounted in parallel metal tubes, and is provided with a fan actuated by clockwork which draws the air with a velocity of two or three feet per second past the bulbs of the thermometers. From the readings of the two thermometers, the relative humidity, vapour pressure, dew-point, &c., can be found by means of Apjohn's formula. To obviate these calculations, *Hygrometric Tables* have been prepared by Mr Glaisher and others, which may be used except in very dry climates or conditions, when Dr Apjohn's formula must be employed.

Hygroscope is a name sometimes given to an instrument for indicating the presence of moisture in the atmosphere without measuring its amount. Hygroscopic substances are those which imbibe moisture and become coated with a moist film.

Hyksos, or SHEPHERD KINGS. See EGYPT.

Hymen, or HYMENÆUS, in Greek Mythology, the god of marriage; but originally the word seems to have denoted only the bridal-song, which was sung by the companions of the bride as she went from her father's house to that of the bridegroom. The god Hymen is first mentioned by Sappho. The legends concerning his birth and descent are various; but he is generally said to be a son of Apollo and some one of the Muses. He is represented as a youth with wings, a bigger and graver Cupid, with a bridal torch and a veil in his hands.

Hymenæa. See LOCUST-TREE.

Hymenomycetes. See FUNGI.

Hymenophyllaceæ. See FILMY FERNS.

Hymenoptera (Gr., 'membrane-winged'), an order of insects, including (*a*) petiolate forms with a narrow waist, e.g. ants, bees, wasps, ichneumon-flies, gall-flies, and (*b*) forms without a waist (Sessiliventre)—the saw-flies. The waist is typically due to a narrowing of the second abdominal segment, the first joining on to the thorax. There are four membranous wings, and the hind pair are usually hooked on to the fore pair; the mouth parts are suited for biting and sucking; the females have a terminal saw, or sting, or ovipositor; the metamorphosis is complete and abrupt; the larvæ are helpless, legless maggots in the petiolate forms; those of the Sessiliventre have legs, and find food for themselves. See ANT, BEE, GALL-FLY, SAW-FLY, WASP, and INSECTS.

Hymettus, a mountain (3368 feet) in Attica, now called Trelo Vouni, situated to the south-east of Athens, was famous among the ancients for its honey and its bluish marble. The honey is still in repute.

Hymn is a word employed in two senses: first, as by the ancient Greeks, to signify a song or poem written in memory of heroes, or dedicated to the gods. This may be taken as the meaning of the word up to the Christian era. Against this the usually accepted definition of a Christian hymn is that of St Augustine: 'Do you know what a hymn is? It is singing with the praise of God. If you praise God and do not sing, you utter no hymn. If you sing, and praise not God, you utter no hymn. If you praise anything which does not pertain to the praise of God, though in singing you praise, you utter no hymn.' The hymns of

the church which are known to us as existing at the time these words were written (c. 415) were mainly of the character thus defined. With the spread of Christianity, however, changes took place which gave rise to another and broader meaning to the hymn. The expansion of church life and the development of doctrine and practice required that fuller liberty should be extended to sacred song. The outcome of this expansion of the original idea and form of the hymn has resulted in the accumulation of vast stores of sacred lyrics, a large proportion of which have passed from time to time into public use in divine worship. The languages and dialects represented therein number more than two hundred.

Of hymns as understood by the first definition, one of the most interesting, from its similarity to civ. psalm, is the song of Akhnaton (q.v.), Pharaoh of Egypt in 1380 B.C., who wrote in praise of the new religion which he had founded, 'the Heat-which-is-in-Aton'; that is, the power which created Aton, or the Sun. It is possible that both Akhnaton's and the Hebrew psalm had a common Syrian source, but it is more than likely that the psalm has been taken from Akhnaton's original hymn. Couched in beautiful language, it is the first known hymn addressed to a monotheistic god. Of ancient Sumerian hymns, such as those sung at the feasts of the deified kings of Ur in the 3d millennium B.C., many are extant to-day owing to careful excavations. The Babylonians and other races produced chants to their gods, and a study of these religions would be incomplete without an inspection of their hymns. More modern are the songs from the sacred books of Taoism, written by Tao Teh K'ing (600 B.C.). The Vedic hymns are the sacred songs of the Brahmans, and are certainly older than the rise of Buddhism, as is shown by the fact that in the oldest Buddhist Sutras the hymns of the three Vedas are constantly referred to, and warnings are uttered against the 4th. They include 'Hymns to the Maruts' (the Storm Gods), and the 'Mandala Hymns,' and are many of them of great beauty.

Numbers of hymns were written in honour of Buddha, but perhaps the most important are those written by Astaghosha, who wrote the *Buddha-Karita-Kāvya* and the *Alamkara-Sastra*.

Although within the Christian era, and in many points conforming to the Augustine definition, the hymns and chants of the followers of Mohammed must be mentioned here. Perhaps the best known is the call by which the faithful are called to prayer, 'God is great; there is only one God, and Mohammed is his prophet. God is great,' a cry which brings together the two definitions under which we are considering hymns.

I. New Testament Hymns.—The early history of Christianity is in our Sacred Books; and to them we must go for the first examples of Christian song—the Magnificat, the Benedictus, the Angelic anthem (see DOXOLOGY), and the Nunc Dimittis. The fourfold record of our Lord's ministry contains no other songs. In the Acts of the Apostles we read of hymns being sung; but of their structure and contents we have no example. On turning to the epistles of St Paul, St James, and St Peter, we have some indications of the nature of the hymns which were then sung. Fragments of what, to every appearance, were familiar hymns in the early church are found therein, some of which are known as the 'faithful sayings' of Holy Writ. These include 'Awake thou that sleepest,' &c., Eph. v. 14; 'If we die with Him, we shall also live with Him,' &c., 2 Tim. ii. 11, 12; 'Manifest in the flesh, justified in the spirit,' &c., 1 Tim. iii. 16; and others, as 1 Tim. vi. 15, 16, Titus, iii. 4-7, and James, i. 17. The songs which St John heard in

vision, although true lyrics, cannot be classed as early Christian hymns.

II. Greek.—(1) In Greek, the mother-tongue of Christianity, it is natural for us, when we have closed the Sacred Record, to search for the earliest forms of sacred song. In the Ante-Nicene period we have a few only, some of which are written in the classical metres, and others which are 'more oriental in character, and have an affinity to the Hebrew modes.'

Of the former the best-known instance is that of Clement of Alexandria (died 220?), translated by Dr Dexter as 'Shepherd of tender youth.' Although Clement's authorship is not beyond doubt, yet it is essentially a hymn of his day, and is absolutely confined, in its subject-matter, to the incidents and doctrines of Holy Writ. The hymns and poems of Gregory of Nazianzus (330-389) are all in classical measures. They were probably written after 381, and number about 240 in all, of which 38 are dogmatic, 40 are on moral subjects, 99 relate to his own life, and 60 more are on miscellaneous subjects. Although amongst these sacred pieces there are several splendid hymns, we know not one in a modern hymn-book. Some of the finest are easily attainable in the original in Christ and Pararikas's *Anthologia Græca Carminum Christianorum* (1871), and in a translated form in A. W. Chatfield's *Songs and Hymns of the earliest Greek Christian Poets* (1876). Another writer in the classical metres was Synesius (375-430). He was an eloquent bishop, and well read in the philosophy of his own and of older days. His ten hymns are also printed in the *Anthologia Græca*, and translated by Mr Chatfield and by Alan Stevenson (1865). One of these hymns, translated by Mr Chatfield as 'Lord Jesu, think on me,' is given in a few modern hymnals. 'Though of great spirit, reality, and beauty,' the 'hymns of Synesius lie confessedly on the borderland of Christianity and Neoplatonism, and often it is the Platonic rather than the specially Christian thought that inspires his most refined passages' (*Dict. of Hymnology*, p. 457). The hymns of Sophronius, patriarch of Jerusalem (629), are of a still later date, as are also those of Elias Synellus and St John of Damascus. Of these hymns in the classical measures none, except three canons of St John of Damascus, were incorporated in the services of the Eastern Church.

(2) The link of connection between the Jewish and the Christian hymnody is found not only in the use which was made from the very first of the Jewish Psalter in Christian worship, but also in the adoption of the ancient 'Hallelujah' and 'Hosanna,' and in the alphabetical and other forms of Christian antiphons and versicles. The primitive Greek hymns, as distinct from hymns of the New Testament on the one hand, and the sacred poems in classical metres on the other, were largely derived from Holy Scripture.

The *Ter Sanctus* is an expansion of Isaiah, vi. 3, and usually reads 'Holy, holy, holy, Lord of Sabaoth: Heaven and earth are full of His glory. Blessed art Thou for ever. Amen.' The germ of the *Gloria in Excelsis* is the Angelic song at Bethlehem. The Greek form of the *Gloria Patri* ('Glory be to the Father,' &c.) seems to have had its origin in Our Lord's commission, 'Go ye therefore . . . baptising them in the name of the Father, and of the Son, and of the Holy Ghost.' Besides these, the *Trisagion*, 'Holy God, Holy and Mighty. Holy and Immortal, have mercy upon us;' the *Cherubic Hymn* of the Greek liturgies, 'Let us who mystically represent the Cherubim, and sing the holy hymn to the Quickening Trinity, lay by at this time all worldly cares, that we may receive the King of Glory, invisibly attended by the angelic orders. Alleluia, Alleluia, Alleluia;' the hymn of Justinian, 'Only-begotten Son and Word of God,' &c.; and various clauses in the *Te Deum* are all based upon separate or accumulated passages of Holy Scripture.

There are also the hymn at lamp-lighting, widely known through Keble's translation, 'Hail! gladdening Light,' which was old in St Basil's time (370); 'The Virgin's Song' of Methodius (died c. 311), translated by Mr Chatfield as 'The Bridegroom cometh!' but not in liturgical use in ancient or modern times; and a few

others. Early Greek hymns are few in number but of fine quality, and deal almost exclusively with scriptural subjects.

(3) The liturgical use of hymns in the church's infancy does not seem to have been extensive. Both Pliny and Justin Martyr bear testimony to their use in public worship, and we know that some were in use in the church of Antioch in 269. 'Yet as late as the 4th and 5th centuries there was a scruple against the use of anything but psalms in the eastern monasteries, and in Spain the Council of Braga (561) forbade the use of hymns' (*Dict. of Hymnol.* p. 460). Ultimately, however, the popularity and power of hymns became so marked through their use by the heretics, and their employment as a counter-check by the faithful, that their exclusion from divine worship became no longer possible. The change was on a limited scale at first, but after the complete separation of the Eastern from the Western Church the hymn in its various forms gradually assumed a prominent and permanent position in the Greek liturgy.

(4) It has been pointed out that the principal link between the early and later hymns is found in a group of pieces discovered by Cardinal Pitra in two rare liturgical MSS. at Moscow and Rome (Cardinal Pitra's *Analecta Sacra Inedita*, Paris, 1876).

(5) The next period (600-900) is that in which we have the building up of those elaborate service-books of the Greek Church, known to us as the *Menæa*, the *Greater Octoechus*, the *Lesser Octoechus*, the *Triodion*, the *Pentecostarion*, the *Euchologion*, and the *Horologion*. In these works the number and variety of hymns are very numerous. The hymn-writers of this period were associated at first with Jerusalem and other parts of the Holy Land, and subsequently with Constantinople.

(a) The first group includes St Andrew, Archbishop of Crete (660-c. 732), who is known as the author of several canons, triodia, and idiomela, including the great canon of the Mid-Lent week. To the English reader he is best known through the cento, made by Dr Neale, 'Christian, dost thou see them?' Almost contemporary with him was St Cosmas, a monk of St Sabas, near Jerusalem, and afterwards Bishop of Maiuma, near Gaza, who died c. 760. He was the author of several pieces, including a canon for Christmas Day, beginning in Dr Neale's translation, 'Christ is born! tell forth His fame.' At St Sabas with Cosmas was John of Damascus, who became a tower of strength in Greek hymnody. Born at Damascus, he accompanied his foster-brother, Cosmas, to St Sabas, and there he wrote his theological works and his hymns. Late in life he entered the priesthood, and died at a great age (c. 780). His influence upon later Greek hymnody was very great. He arranged the *Octoechus* in accordance with the Eight Tones, and supplied it with several canons of great merit. His canons are his finest work, that for Easter (beginning in Dr Neale's translation, 'Tis the day of Resurrection') being well known, in part at least, to the English reader. Within the next fifty years St Theophanes, a native of Jerusalem, also of St Sabas, and afterwards Archbishop of Mida, was writing extensively on the martyrs and confessors of the Greek Calendar, which took the form of canons and idiomela. Although largely represented in the *Menæa*, he is almost unknown to the English reader.

(b) The second group of hymn-writers were associated with Constantinople. The first of these is Joseph the Hymnographer (died 883), a native of Sicily, but afterwards founder of a monastery at Constantinople. He was one of the most voluminous of the Greek poets, and is largely represented amongst the canons in the *Menæa*. His canon for Ascension Day is very fine. Of it, however, but a small portion is familiar to English readers, Ode iv., translated by Dr Neale as 'Jesus, Lord of life eternal,' being the best known. 'Let our choir new anthems raise,' and 'Stars of the morning so gloriously bright,' are also translations by Dr Neale from St Joseph. St Joseph of the Studium, sometime Bishop of Thessa-

lonica, wrote several pieces; but none of them have been translated into English. His elder brother, St Theodore of the Studium (died 826), wrote several canons, notably that on the Judgment, translated by Dr Neale as 'That fearful day, that day of speechless dread,' and regarded by Neale as 'undoubtedly the grandest judgment-hymn of the church previous to the *Dies Irae*.' He also wrote 'A song, a song of gladness,' which is a part of his triumphal canon on the victory of the Icons. Methodius II. (died 836) also belongs to this group of poets. Of the few pieces which he wrote Dr Neale has translated one only, 'Are thy toils and woes increasing?' and has given it as by St Methodius I. in error. Theoctistus of the Studium (c. 890), said by Dr Neale to have been a friend of St Joseph's, is not largely represented in Greek hymnody. He is known to English readers through Dr Neale's translation of a cento from his 'Suppliant Canon to Jesus,' as 'Jesus, Name all Names above,' and the Rev. R. M. Moorsom's rendering of the same, 'Sweet Saviour, in Thy pitying grace.'

(6) From this date to the 16th century, when the Greek service-books were practically closed against new compositions, very few names are known. We have Metrophanes (died 910); Euthymius (died 910); Constantine Porphyrogenitus (913-959); Leo VI. (died 917); John Mauropus (died 1060); and Philotheus, Patriarch of Constantinople (died 1376); but only one or two pieces by these writers have been rendered into English.

III. *Syriac* (170-1370).—Syriac hymnody deals with the churches of Syria, Upper Mesopotamia, and western Persia. Its history extends from the 2d to the 14th century.

The earliest known hymn-writer in this language is Bar-Daisan (Bardesanes, q.v.), born in 154. His son Harmonius was also a hymn-writer. Both father and son had Gnostic tendencies. On the orthodox side we have Simeon bar Sabbae, Bishop of Seleucia, who suffered martyrdom in 296; and the greatest of all, Ephraem Syrus (q.v.; c. 306-378). His poetical writings were numerous, and included homilies, discourses on Christ's Nativity, the Creation, and other subjects. Most of the Syriac hymns and hymnists are practically unknown to the western world. In the East, however, these hymns form a considerable portion of the service-books of the various divisions of the Syriac churches to the present day. Their English use is very limited. The best-known example is 'Glad sight, the holy Church,' by the Rev. F. Pott.

IV. *Latin*.—(1) No name is associated with Latin hymns until after the Council of Nicea, 325. Almost immediately afterwards we have three great contemporary writers: in Greek, Gregory of Nazianzus (330-389); in Syriac, Ephraem Syrus (306-378); and in Latin, St Hilary (died 368). The most celebrated of the hymns attributed to the last is the 'Beata nobis gaudia Anni reduxit orbita,' which has been in western liturgies from an early date. St Ambrose (c. 340-397) was almost a contemporary writer with the above three. About 100 hymns are attributed to him, but of these only twelve are accepted by the Benedictine editors of his works, including 'Æterna Christi munera,' 'Deus Creator omnium,' 'O Lux beata Trinitas,' and 'Splendor Paternæ gloriæ.' The rest, being in his style and after his manner, are known as Ambrosian hymns. Most of the latter and all of those by St Ambrose are found in the early liturgies of the Western Church. Prudentius (350-410) did not write hymns, but sacred poems, from which portions were taken and incorporated as hymns in the services of the church. For this purpose these extracts were admirably suited and widely used. His 'Corde natus ex Parentis,' which was taken from his poem 'Da, puer, plectrum,' in his *Cathemerinon*, is a good example of this mode of treatment. The 63d edition of Prudentius' *Poems* was published at Leipzig in 1860. This is a splendid testimony to his worth. Sedulius, a contemporary of Prudentius,

is known in hymnology by one piece, 'A solis ortus cardine, Ad usque,' of which the second portion, 'Hostis Herodes impie,' is used as an Epiphany hymn in several early breviaries, and altered, as 'Crudelis Herodes Deum,' in the modern Roman Breviary. The 6th century embraces two names of great repute: Venantius Fortunatus (530-609), and Gregory the Great (540-604). Fortunatus' *Poems* are extant in eleven books. Some ten or twelve hymns bear his name, but his right to several of these is contested. His grandest productions are the Passiontide hymns, 'Vexilla Regis prodeunt' and 'Pange lingua gloriosi prælum certaminis.' Gregory's accredited hymns are about a dozen, including 'Audi benigne conditor,' 'Ecce jam noctis,' 'Rex Christe factor omnium,' and 'Summi largitor præmii.' The fairly well authenticated hymns of the Venerable Bede (673-735) number ten or twelve only at the utmost, including his 'Hymnum canamus Domino,' and 'Hymnum canentes martyrum.' Another hundred years give us Paul the Deacon (died c. 799) and St Theodulph of Orleans (died 821), the 'Gloria laus et honor' of the latter being long and well known as a processional hymn for Palm Sunday. St Rabanus (776-856), with his 'Christe Sanctorum decus Angelorum,' and St Odo of Cluny (879-942), with his 'Lauda, mater ecclesia,' should be mentioned, as also Fulbert of Chartres (died 1028), author of the 'Chorus novæ Hierusalem,' and Robert II., king of France (972-1031), though their claims to hymn-writing are open to question.

(2) Although this brings us to the beginning of the 11th century, the hymn-writers whom we have been enabled to cite are comparatively few. Most of them, however, are names of great standing, and are towers of hymnological strength. When, however, all the compositions of these writers are collected together we still find in the ancient Latin service-books and other MSS. a mass of hymnological literature for which no authorship can be found. This is also the case with regard to the succeeding centuries, and more especially with respect to the Prose or Sequence.

(3) Notker Balbulus (c. 840-912), the father of sequence-writing, was a member of the Benedictine monastery of St Gall, his principal work being literary and scholastic. In connection with divine worship he found it difficult to remember the musical notes (*neumes*) set to the 'Alleluia' (specially to the final *a*), which were sung between the reading of the Epistle and the Gospel. The adapting of words to these *neumes*, instead of sounding them as musical notes only, was suggested to him by another, and the result was a series of Sequences, or, as we now call them, hymns, which to the number of 115 are known as Notkerian Sequences, but of which less than fifty are by Notker. Of those who followed Notker in this mode of composition Adam of St Victor (an abbey at Paris) was the most prominent. The service-books of the middle ages abound with these compositions, but the greater proportion by far are anonymous. The Notkerian Sequence which is best known to the English reader is that for the Epiphany, translated by Dr Neale as 'The strain upraise of joy and praise. Alleluia.'

(4) Whilst the work of composing hymns and sequences was thus prolific, a few names of great note stand forth in their grandeur as composers of sacred poems as distinct from hymns. It will be sufficient to name St Bernard of Clairvaux (1091-1153), and his grand Passiontide poem 'Salve mundi salutare,' and his contemporary, Bernard of Cluny, with his splendid 'Hora novissima,' to show the nature and character of the work which was done. See *DIES IRÆ*.

(5) The hymns, sequences, and poems referred

to above, to the number of several thousands, are those which date from before the 16th century. Some hundreds more were added to the stores of Latin hymnody by the brothers Santeuil and others in the Cluniac (1686), the Paris (1736), and other breviaries in France, additions to the latter being as late as 1820. As to the use made of this mass of sacred poetry, we may add that two-thirds or more have been associated directly with divine worship, and the rest are connected with works of private devotion; and that nearly one-fourth have been translated into English.

V. *English*.—English hymnody is a very wide subject, and, if we include therein Anglo-Saxon compositions, it dates from Cædmon (died c. 680). Bishop Aldhelm (died 709) sang sacred poems in the vernacular, and is said to have rendered the Psalter into metre; in Chaucer (1340-1400) we have an early English hymn to the Blessed Virgin; in 1414 T. Brampton's Seven Penitential Psalms, and later carols and additional hymns to the Blessed Virgin Mary. The first instalment of hymns in the vernacular of any moment were those translated from the Latin, and included in the Primers which were issued both before and after the Reformation. These translations were followed by others, some of which are preserved to us in the Book of Common Prayer. Translating, however, soon gave way to paraphrasing, and Latin and German hymns to the Book of Psalms. The supplying of the need occasioned by the suppression of Latin hymns in divine worship at the Reformation, by the introduction of the Paraphrase instead of the hymn, is a history in itself. We can only say that from 1561 to 1696 the authorised book in the Church of England was the 'Old Version' of Sternhold and Hopkins, and from the latter date to the adoption of modern hymn-books, the 'New Version' of Tate and Brady. In the meantime the foundations of English hymnody were being extended. A *résumé* of the work done in the Elizabethan age is given in E. Farr's *Select Poetry, chiefly devotional, of the Reign of Elizabeth* (Parker Soc. 1845). The specimens given are either from books of poetry or works of devotion, and are pious utterances in quaint and rugged verse. Later attempts in the same direction, by Dr Donne in his *Poems* (1633), G. Herbert in his *Temple* (1633), C. Harvey in his *Synagogue* (1640), and others, were of a higher stamp, and bore a greater affinity to the modern hymn. At that time no use of these compositions was made in public worship, except in the case of private institutions. The hymn 'Jerusalem, my happy home,' and others of more than usual excellence are of this period.

The first English hymn-book was the *Hymns and Songs of the Church* (1623), by George Wither. The king granted him a patent to bind up the book with the Metrical Psalms; but the whole matter resulted in a failure. In 1641 Wither republished the same, with a few alterations, as *Hallelujah, Britain's Second Remembrancer*, and dedicated it to the Long Parliament, but with no better success. The writings of Herrick, Henry Vaughan, William Barton, Bishop Jeremy Taylor, Samuel Crossman, Richard Crashaw, John Austin, Bishop Thomas Ken, and others bring us down to 1737, when the first hymn-book of the modern type (in which the original hymns of various authors are interspersed with translations from other languages) was published by John Wesley for use in the Church of England.

(1) *Church of England*.—The title of Wesley's book was *Collection of Psalms and Hymns* (Charlestown: printed by Lewis Timothy, 1737). The versions of psalms, the translations from Greek and German, and the original compositions were

seventy in all. Wesley and his brother Charles soon changed the style of their hymnological productions, and from 1740 to 1780 (the date of the Wesleyan hymn-book) published only their own compositions. John Wesley's hymnological work for the Church of England remained a dead-letter until 1760, when Martin Madan published his *Collection of Psalms and Hymns*, gathered by him mainly from the Wesleys and Isaac Watts, altered without permission to suit his Calvinistic views, and published without leave.

During 1760-1800 nearly twenty distinct hymn-books were issued. Taken as a whole they were Calvinistic in doctrine, crude in arrangement, and indebted to the Wesleys and Nonconformists for seven-eighths of their contents. Three Church of England writers only stand out during this period with marked distinctness—A. M. Toplady, John Newton, and William Cowper. During the next twenty years nearly one hundred hymn-books were issued for use in the Church of England, and the places of publication extended to almost every county in the country. Naturally these books varied in their contents; but their general doctrinal tone was distinctively Calvinistic. There was also a greater and more uniform recognition of the order of the Book of Common Prayer than before. The years 1820-50 produced another hundred of hymn-books, amongst them Bickersteth's *Christian Psalmody* (1833-41), Elliott's *Psalms and Hymns* (1835), and Hall's *Mitre Hymn-book* (1836). Other works of importance were Bishop Heber's posthumous *Hymns* (1827), Miss Auber's *Spirit of the Psalms* (1829), Bathurst's *Psalms and Hymns* (1831), and Lyte's *Spirit of the Psalms* (1834), the contents of which, in each instance, were mainly by the same writer. During this period also this store was richly increased by the publication of Keble's *Christian Year*, by the original compositions of several other writers, and by renewed efforts at translation of German and Latin hymns. This immense growth broadened out considerably, and brought the subject of hymnody strongly to the front during the next ten years. The outcome was the publication of over fifty hymn-books in that period, a great accumulation of original hymns and translations, the gradual exclusion of nonconformist hymns, except those of the higher class, from the collections, and a new and intense interest in the whole subject. Additional translations from the Latin and German, together with original compositions of great merit, created a longing for something better in the form of a hymn-book for public use. *Hymns Ancient and Modern* (1861) was one answer to this request. Its success was prodigious. On the one hand it raised a storm of opposition; on the other, during the next twenty-five years it called forth several important works on hymnology, various collections of sacred lyrics for private use, about fifty 'supplements' to and editions of books in common use, and nearly one hundred new hymn-books. Since then new writers whose names have become household words have arisen, and the needs of the increased activity of the church have been met. In the past one hundred and fifty years the Church of England has produced about five hundred hymn-books, and nearly two hundred and fifty authors and translators whose hymns and translations, used in public worship, may number ten thousand. *The English Hymnal*, issued from the Clarendon Press in 1906, represented 'high' doctrine and offended evangelical feeling. In 1916 a new Supplement was issued, but it conforms in great degree to the moderate standard of 1889. It adds 141 hymns, which are more modern than ancient.

(2) *English Nonconformists*.—The hymnological work which has been accomplished outside of the Church of England is large and important, and has had great influence in all English-speaking countries. A few facts only can be set forth in each instance.

(a) *The Baptists* from the first quarter of the 17th century to the present have been divided into two sections, the Particular or Calvinistic, and the General or Arminian Baptists. The singing of hymns with the former began with B. Keach about 1673. It had a stormy birth and childhood, for opposition thereto was great, but at the present time hymn singing is a distinctive feature in their worship. The General Baptists

also have their official hymn-books, and singing is an essential part of their worship. English Baptist writers number about one hundred, and their hymns two thousand.

(b) *The Congregationalists* or Independents used hymns in public worship some thirty years before the Baptists. Their hymn-books have been many, and their writers numerous. The latter number over a hundred, and their hymns three thousand or more. Although I. Watts, P. Doddridge, and J. Conder are their pride and towers of strength, there are others who have written lyrics of great force and beauty.

(c) *The Methodists*, including the different branches into which they have broken at various times, have always been very fond of hymns. The first official hymn-book of the old body was published by J. Wesley in 1780, and is the groundwork of all the hymn-books of the various branches of Methodism—the Primitive Methodists alone excepted.

(d) *The Unitarians* have produced several hymn-writers of great merit. Of their hymn-books Dr Martineau's *Hymns of Praise and Prayer* (1873) is admirable.

(e) The Irvingites, the Swedenborgians, the Salvation Army, and others have also their authors and official hymn-books.

(3) *Roman Catholics*.—*The Westminster Hymnal*, issued by authority in 1912, was selected by a committee of bishops, and represents the best of those which have become popular since the singing of hymns in the vernacular has become an important part of the non-liturgical services of the Roman communion in the country.

When English hymn-writers are counted up and their works are tabulated, we have a total of some 1000 writers, and 25,000 hymns.

VI. *Irish*.—Roman Catholics, Protestant Episcopalians, Presbyterians, Methodists, and others in Ireland have been so closely identified with their brethren in England and Scotland that in most instances the same books have been in use in the three countries, although in later years a few hymn-books have been published independently. The Irish Church published an authorised hymnal, *The Church Hymnal*, in 1873, with supplement of later date.

VII. *Welsh*.—There are references in Welsh history which go to show that some of her ancient bards sang hymns of praise to God as early as the 6th century. The most ancient productions now extant date from the 14th century. After the Reformation the lead was taken by the Established Church, by the publication of Archdeacon Prys's version of the Psalms in 1621. Since then hymn-writing has increased somewhat rapidly, especially since the Methodist movement early in the last century; and at the present time the Established Church and the numerous Nonconformist bodies have each their official or quasi-official hymn-books. Welsh hymnody, although very powerful in the principality, has had little or no influence upon the hymnody of other countries.

VIII. *Scottish*.—One of the most interesting parts of Scottish hymnody is the history of the Scottish Psalter, a work which is interwoven with Scottish history, and has had a powerful influence upon the Scottish mind. The first effectual step taken to provide hymns, as distinct from psalm-versions, for public worship in Scotland, was the appointment of a committee of the General Assembly in 1742. This committee presented a draft collection, which was authorised for private use in 1745. The same year a committee was appointed to revise and enlarge the draft for public use. The result was published in 1781 as *Translations and Paraphrases, in Verse, of several Passages of Sacred Scripture, &c.* Of the total contents (sixty-seven in all, not counting the five hymns added at the end) twenty-five are by Watts, five by Doddridge, and two by

Tate, the rest being by M. Bruce, T. Blacklock, H. Blair, W. Cameron, J. Logan, J. Morison, and other Scottish writers.

Although the addition of the five hymns to the Paraphrases indicated a desire for a larger choice of hymns in public worship, nothing definite and official was done by the principal sections of Presbyterianism until the publication of the *Hymn-book of the Relief Church* (1794), the *Hymn-book of the United Presbyterian Church* (1852), *The Scottish Hymnal of the Established Church* (1870), and the *Psalm-versions, Paraphrases, and Hymns of the Free Church* (1873). These have been revised, added to, or superseded—notably by the carefully edited *Church Hymnary* for the Scottish and Irish Presbyterian Churches (1898), revised in conjunction with the English and Welsh Presbyterian Churches (1925). Much activity has been shown by individuals amongst Presbyterians, Episcopalians, Baptists, Congregationalists, Roman Catholics, and others, the outcome of which is a mass of hymnological literature, of which a good proportion is of Scottish origin and of high merit. The prince of hymn-writers and the Charles Wesley of Scotland is Dr Horatius Bonar (1808-89).

IX. *American*.—The first book printed in America was the Bay Psalter (1640), consisting of various metrical versions of the Psalms by English authors. The addition of a few spiritual songs in the 2d edition of 1647 was the first departure from the sole use of psalm-versions in that country. This small beginning had at the first a very slow development. The years 1780-1800 witnessed the general recognition of hymns. The Protestant Episcopal Church extended their collection in 1789 to twenty-seven hymns: a collection by the Baptists (the second) was published in 1790; the Congregationalists had their *Hartford Selection* in 1799; the Wesleyan Methodists a reprint of a *Pocket Hymn-book* originally published at York, and revised after some years of use in 1802; the Universalists, two collections in 1792; the Unitarians, a selection in 1795; and the Presbyterians, Watts at first, and then an official collection in 1828. In these books American hymn-writers had a very limited representation, most of the hymns being by English authors; but year by year the American element became more pronounced as hymnal followed hymnal in the various religious communions. In 1800 an original hymn by an American was a novelty in any collection; now no American hymn-book of the highest class can do with less than two hundred and fifty authors and translators, and of these not less than fifty should be Americans. This percentage, as the outgrowth of some eighty years, is remarkable. Each religious communion has done its part in bringing about this great result. Of the two hundred and fifty authors and translators, the Baptists and the Unitarians number over forty-five each, the Congregationalists about forty; the Protestant Episcopalians and the Presbyterians about thirty each, the Methodists less than twenty, and the Universalists about ten. The remaining thirty include Quakers, Reformed Germans, Reformed Dutch, &c. Several of these writers have an European reputation, as Bishop Cox, Bishop Doane, C. W. Everest, and W. A. Muhlenberg (Episcopalians); T. Hastings and J. W. Alexander (Presbyterians); H. M. Dexter, T. Dwight, and Ray Palmer (Congregationalists); P. Bliss, Lydia Sigourney, and S. F. Smith (Baptists); Fanny Van Alstyne and W. Hunter (Methodists); S. G. Bulfinch, W. C. Bryant, W. H. Burleigh, Emerson, Holmes, Longfellow, S. Longfellow, Lowell, and E. H. Sears (Unitarians); and the Quaker poet Whittier.

The number of hymn-books published in America

during the past hundred years accounts to a great extent for this great activity in hymn-writing. At the present time each denomination, and there are many, has its official hymn-book, or its quasi-official book or books. For good work opportunities for publication thus abound, and the finer productions are assured a certain circulation and a possible immortality.

X. *French*.—The French metrical psalters have a history distinct from French hymns and hymn-books. The complete psalter of Marot and Beza (1552-62) was the psalm-book of the Reformed Church until its place was to some extent filled by the new version of Conrart (1677-79), and the revision of the same by Pictet and others in 1695. As in other countries, the psalter subsequently gave way to the hymnal, and the versions of private individuals were mainly of public value in proportion as they yielded suitable pieces for the same. The writing of hymns in the vernacular began in the 16th century as in Germany and elsewhere with translations from the Latin. The Roman Catholics, the Huguenots (in their day), the Reformed Church, the French Moravians, the Methodists, and various evangelical societies, have each their book or books of hymns for divine worship, in which, although there are original compositions by French authors, the larger proportion are translations from English and German hymns. *The Réveil* has produced the greatest French Protestant hymn-writers, at the head of whom stands César Malan (1787-1864), whose printed and MS. hymns number about one thousand. Associated with him, directly or indirectly, in the same religious movement were Ami Bost, H. Empaytaz, Merle d'Aubigné, Felix Neff, Henri Lutteroth, A. Vinet, A. Monod, and others, men of world-wide reputation and influence, who have given a position to French hymnody unknown to it before.

XI. *German*.—In the German language there are not less than one hundred thousand hymns, of which about ten thousand have passed into German hymn-books of various dates, and nearly a thousand are regarded by German critics as classical. The first were contemporary with the earliest Latin sequences of St Notker and others; the last are the productions of living men.

(1) *The First Period* begins with Otfrid of Weissenburg (c. 868), and was continued by others until the time of Luther. The greater part of the hymns of this period were translations from the Latin, and all were in strict doctrinal accord with the Church of Rome.

(2) *The Second Period* (1520-1648) opens with the hymns and psalm-versions by Luther, and embraces the Reformation period to the peace of Westphalia. The principal writers were Luther, Justus Jonas, Alber, Spengler, Hans Sachs, Speratus, N. Decius, and others. The writings of these authors reached to about 1570, and have a distinct churchly character of their own. From 1577 to 1618 hymn-writing and hymn-book making continued very much on the old lines, and numbered amongst the writers Selnecker, Ringwaldt, Herberger, and P. Nicolai. The miseries of the Thirty Years' War changed the whole aspect of hymn-writing for a time by the introduction of a strong personal element of faith and courage, and hope begotten of suffering. The names of a few of these writers will recall some of the finest hymns of this kind in the German language: Opitz, Haermann, M. A. von Löwenstern, Altenburg, Rinkart, Dach, and Rist.

(3) *The Third Period* was a transitional one, and led up to the Pietistic and Moravian writers of the next era. It had amongst its hymn-writers P. Gerhardt, Franck, Neumark, Scheffler, and Louise Henriette of Brandenburg. Of these the greatest were Gerhardt, who is second only to Luther in German hymnody, and Scheffler, whose love for Christ was first in everything. This orthodox, mystic school, with its deep experimental piety, was soon lost in the Pietism of the next period.

(4) *The Fourth Period*, commonly known as the

Pietistic and Moravian era, 'was a reaction against the dry scholasticism and cold formalism of the Lutheran Church,' and an emphatic pronouncement in favour of 'practical, personal, and experimental piety.' On the Lutheran side the leading writers were Spener, Francke, Richter, Freylinghausen, G. Arnold, J. Lange, Dessler, Rambach, Bogatzky, Schmolk, and Hiller; and on the Moravian, Count Zinzendorf. These names recall numerous hymns of deep spirituality, high refinement, and great power.

During this same period the German Reformed Church broke away from its long-continued and almost exclusive use of the Psalms in metrical form. Their first hymn-book appeared at Zurich in 1540. This was followed by A. Lobwasser's rhymed translation of the French Psalter of Marot and Beza in 1573. Another hundred and fifty years brought them into closer hymnological conformity with their Lutheran brethren, and produced amongst others three well-known hymn-writers, J. Neander, Lampe, and Tersteegen.

(5) *The Fifth Period* embraced about sixty years (1757-1817), and covers the time when the great wave of Rationalism broke in upon the German churches and for a time changed the whole aspect of their hymnody. Old hymns were altered or entirely rewritten, and new hymns written partaking of the nature of rhymed sermons on the existence of God, the immortality of the soul, the dignity of man, the obligations of moral duties, and kindred subjects. To the hymn-writers of this order there were a few notable exceptions, which included Gellert, Klopstock, J. C. Lavater, and M. Claudius, the greatest being Gellert and Klopstock.

(6) *The Sixth Period* is rich in writers. Beginning almost with the 19th century, it extends to the present time, and embraces the well-known names of F. von Hardenberg ('Novalis'), E. M. Arndt, F. A. Krummacker, F. W. Krummacker, A. Knapp, J. P. Lange, Spitta, and Gerok.

This digest of the hymnological work of more than a thousand years in one language can give only the slightest idea of what was done. Little or nothing has been said about the multitude of hymn-books (*Gesangbücher*) which were issued and brought into common use in the church and in the home, nor of the metrical versions of the Psalms, which have a history of their own. We can do no more than recall and emphasise the facts, and refer to special treatises for details. The influence of German hymns upon English and American hymnody has been very great. In fact, until the modern revival of translating hymns from the Latin and other languages, German was almost the only source from whence hymns other than English were taken for use in the hymn-books of Great Britain and America; and at the present time, especially in America, it holds a prominent position in the hymnals of almost every party and creed. For the Dutch, Italian, Bohemian, Moravian, and Scandinavian hymns, and those in use in foreign missions (in more than 150 languages and dialects), see J. Julian's *Dictionary of Hymnology* (1892; new ed. 1907).

Conclusion.—From the outset of the propagation of any religion throughout the nations of the earth it became a necessity to preach to the people in their own languages, and gradually to supply them with hymns in their own tongues. This has resulted, as we have seen, not only in a great number of languages being represented in Christian hymnody, but also in a vast variety of metrical forms being found therein. Some of these forms are intimately associated with the ancient classical measures, whilst others are widely divergent therefrom, and seem to have had little or no laws of control beyond the fashion of the period or the fancy of the writers. With this broadening out of languages and forms came also a rapid increase in the number of subjects which engaged the attention of Christian poets. At an early stage of church history reverent strophes in praise of the Holy Trinity, and especially in adoration and praise of the Eternal Son,

together with a metrical homily or two and a few impassioned songs on the practical side of Christian life, formed the staple of sacred song. We have seen how the expansion of church life and the development of doctrine and practices called forth a fuller and more extended hymnody, until every incident of importance in Bible story, every conceivable shade of Christian doctrine and ritual, every epoch in the church's history, every experience in her children's life, from the sufferings of her little ones to the magnificent self-sacrifices of her martyrs, have been enshrined in sacred song. See Dr L. F. Benson, *The English Hymn* (1916).

Hyndman, HENRY MAYERS, born in London 7th March 1842, and educated at Trinity College, Cambridge, was a correspondent in the war of 1866. He associated with Mazzini and other Italian leaders, and wrote and spoke for free institutions elsewhere. Marx's writings made him a socialist. He founded the Social Democratic Federation (see SOCIALISM) in 1881, and was prominent in other organisations. Opposed to the Boer War, he yet developed later into a vigorous anti-German propagandist. He wrote, besides books on democracy, socialism, Clemenceau, and Asia, *The Record of an Adventurous Life* (1911). He died 22d November 1921. See *The Last Years of H. M. Hyndman* (1923) by his second wife, Rosalind Travers, a thorough-going admirer.

Hyōgō. See KOBE.

Hyoid Bone, in human anatomy, is a bony arch consisting of five movable parts, quite separate from the rest of the skeleton, and lying in the fleshy parts of the neck between the root of the tongue and the larynx (see TONGUE). For the hyoid bone of the dog, see the figure at DOG.

Hyoscyamus, Hyoscyamin, Hyoscin. See HENBANE.

Hypatia, daughter and pupil of Theon, an astronomer and mathematician of Alexandria, was born in the later part of the 4th century A.D. Her learning and wisdom made her the most influential teacher in Alexandria, and the fame of her lectures drew round her students from all parts of the East, where the influence of Greek thought and knowledge was felt. The philosophy she taught seems to have been an eclecticism, the results of an endeavour to combine Neoplatonism with Aristotelianism; but her thoughts were principally given to astronomy and mechanics. Personally she was held in such great esteem, and such reliance was placed on her judgment and sagacity, that the magistrates used frequently to consult her on important cases. At this time the Bishop of Alexandria was Cyril (q.v.), a fierce hater of heathens and heretics. With his connivance, if not at his instigation, certain savage monks from the Nitrian deserts, headed by one Peter, a reader, attacked Hypatia in the streets as she was returning from her lecture-room, dragged her from her chariot, hurried her to the Casareum (then a church), there stripped her naked, and hacked her to death with oyster shells, after which she was torn to pieces, and her limbs carried to a place called Cinaron, and there burned to ashes (415). None of her writings have survived. Kingsley's romance, *Hypatia*, appeared in 1853.

Hyperæsthesia (Gr. *hyper*, 'over,' *æsthēsis*, 'a sensation'), in the most general sense of the word, denotes an excessive excitability of the parts of the nervous apparatus which have to do with sensation, special or common. Abnormal sensibility to pain is, however, more correctly called *hyperalgesia*. In this condition, as exemplified in neuralgia, the slightest stimulus may cause a paroxysm of pain, even a current of air or a noise bringing on

an attack; while in hyperæsthesia of the special senses bright flashes of light may be seen, sounds may be heard, and even smells and tastes experienced in the absence of any objective cause. Of the diseases predisposing to hyperæsthesia hysteria is far the most frequent; but it is sometimes induced by rheumatism, gout, skin diseases, inflammatory affections of the central nervous system, while it often adds greatly to the distress in the early stages of various fevers. The treatment of hyperæsthesia is that of the morbid change on which it depends, but the local application of anodynes, ice, or warm poultices, and sometimes the use of electricity may do much to diminish the patient's sufferings for the time.

Hyperbola. If two similar cones be placed apex to apex, and with the lines joining the apex and centre of base in each, in a straight line; then if a plane which does not pass through the apex be made to cut both cones, each of the two sections will be a *hyperbola*, as PBN, P'AN'.

It is, viewed analytically, the locus of the point to which the straight lines EP, FP differing by a constant quantity are drawn from two given points, E and F. These given points are called the *foci*, one being situated in each hyperbola. The point G, midway between the two foci, is called the *centre*, and the line EF the *transverse axis* of the hyperbola. A line through G perpendicular to the transverse axis is called the *conjugate axis*; and a circle described from centre G, with a radius equal to FG, will cut the conjugate axis in C and D. If G be taken for the origin of co-ordinates, and EM and E'F' for the axes, the hyperbola is expressed by the equation $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$. (GB = a , GC = b).

The hyperbola is the only conic section which has Asymptotes (q.v.); in the figure these are GT, GT', GS, GS'. It also appears that, if the axes of co-ordinates be turned at right angles to their former position, two additional curves, HCK, H'DK', will be formed, whose equation is $\frac{x^2}{b^2} - \frac{y^2}{a^2} = 1$. These

two are called *conjugate hyperbolas*, and have the same asymptotes as the original hyperbolas. These asymptotes have the following remarkable property: If (starting from G) the asymptotes be divided in continued proportion, and from the points of section lines be drawn parallel to the other asymptote, the areas contained by two adjacent parallels and the corresponding parts of the asymptote and curve are equal; also, lines drawn from the centre to two adjacent points of section of the curve enclose equal areas. The equation to the hyperbola when referred to the asymptotes is $xy = ab$; which shows that as the ordinates decrease in geometrical progression the abscissæ increase in the same ratio.

The hyperbola is also the locus of a point whose distance from a fixed point (one of the foci) has a constant ratio e , greater than 1 (called the *eccentricity*), to its distance from a fixed straight line (the *directrix*).

Hyperboreans (i.e. dwellers beyond Boreas

or the North Wind), a name given by the ancients to a mythical people, whose land was generally supposed to lie in the extreme northern parts of the world. As the favourites of Apollo, they enjoyed an earthly paradise, a bright sky, a perpetual spring, a fruitful land, unbroken peace, and everlasting youth and health. Some ethnographers have used the term Hyperboreans to designate certain peoples, such as the Tchukcheis, Ainu, Kamchadales, &c., in Arctic Asia and America.

Hyperdulia, the superior dulia accorded by Roman Catholics to the Virgin Mary (q.v.).

Hypericaceæ, an order (or sub-order of Guttifera) of about 300 known species, trees, shrubs, and herbs, widely distributed over the world, particularly numerous in North America. Many belong to the genus *Hypericum*, or St John's Wort (q.v.).

Hyperides (more correctly Hypereides), the Greek orator who, on the whole, ranks next to Demosthenes, excelling him in grace though inferior to him in moral power, was probably born about the same time as Demosthenes. By birth belonging to the middle class, he became a professional advocate, and earned large sums of money, which he spent with a generous hand alike on his private (somewhat scandalous) pleasures and on patriotic purposes. His *eisangelia* against Philocrates assured his professional position and brought him on to the stage of politics, where he was destined to play a notable part (343 B.C.). From the first he was an opponent of the party which advocated peace with Philip, and a supporter of Demosthenes. The importance which attached to him as a politician at this time is shown by the fact that he was chosen by the Areopagus to represent the Athenian case before the Amphictyons in the dispute as to the control of the Delian temple. During all Demosthenes' manful struggles against Philip up to the fatal field of Chaeronea, when, with the defeat of Athens, the political liberty of Greece practically came to an end and the supremacy of Macedonia was established, Hyperides was the trusty and valuable supporter of Demosthenes. Even after the death of Philip, and during the early portion of Alexander's career, the two orators continued to be faithful allies. Only when Demosthenes endeavoured to follow an impossible *via media* in the matter of Alexander's absconding minister, Harpalus, did Hyperides break with his former leader, and head that accusation of bribery against Demosthenes which not only resulted in the banishment of the great orator but committed Athens to the fruitless revolt against Macedon, known as the Lamian war. The leaders of this revolt were Leosthenes and Hyperides; the former perished in battle, the latter was put to death by Antipater (322 B.C.). It is remarkable that although Hyperides was admired and studied in Roman times, although his works were not only known to Photius in the 9th century but actually preserved in MS. in the King's Library at Buda until 1526, when Buda was taken by the Turks, it was not until 1847 that we had any specimens of Hyperides' oratory by which to judge for ourselves of his powers. In that year Mr A. C. Harris of Alexandria purchased a papyrus at Thebes containing portions of Hyperides' speech against Demosthenes and of his speech for Lycophron. At the same time Mr J. Arden was offered a papyrus, while he was travelling in Egypt, which turned out to belong to the same volume as that bought by Mr Harris, and to contain the remainder of the speech for Lycophron, and also the whole of the speech for Euxenippus. In 1856 another traveller, Mr Stobart, obtained from the same neighbourhood another papyrus containing the Funeral Oration of Hyperides. In 1889 M. Eug. Revillout an-

nounced that the Louvre had on his proposition purchased a papyrus which contains fragments of the first speech against Athenogenes; and in 1893 Mr F. G. Kenyon published his standard edition, with an English translation, of the orations *Against Athenogenes* and *Pheidippides*.

What most impresses one in reading Hyperides is his grace, next his indolence, and always his urbanity. His grace is nothing affected or assumed, nor is it useless ornament. Hyperides is a practical, not an epideictic orator, and means business. His grace is that of a man performing a feat well within his powers, and that not a despicable feat. At the same time he is indolent, apparently because there is really no need to exert himself. He will not take the trouble to pick and choose words; he makes the one that comes first—obsolete, obsolescent, proverbial, conversational, or what not—do his work. He will not turn his sentences over mentally again and again before uttering them, so that they may roll out smooth, polished, balanced, and finished: he will rather let them come out at their own length, and as they list—he can pull them up at any time with effect and without effort. He is always transparent, never monotonous as is Demosthenes; he is witty to a degree, refined in his raillery, and his irony is delightful. Above all he never in his keenest attacks passes the bounds of good taste, as does Demosthenes. See Blass's edition (1894).

Hyperion, a Titan, son of Uranus and Ge, and father of Helios, Selene, and Eos. Homer and later poets apply the name to Helios himself.

Hypersthene (Gr. *hyper*, 'above,' *sthenos*, 'strength'; so called to distinguish it from Hornblende (q.v.), with which it was formerly confounded), a rock-forming pyroxene which crystallizes in orthorhombic forms. It is an anhydrous magnesian silicate, containing a large percentage (16-31) of ferrous oxide with very little alumina. It is generally dark green or raven-black, but has a pearly or metallic lustre when fractured across the cleavage-planes. This is due to the presence of very numerous minute brown scales of some foreign substance, which are arranged mostly parallel to the basal plane. It is best known from its occurrence in large crystals in plutonic rocks such as gabbro and norite; it is, however, also an essential constituent of certain fine-grained eruptive rocks such as hypersthene andesites, which are extensively developed in many parts of the world.

Hypersthénite, a term now applied to varieties of peridotite which consist almost entirely of hypersthene; used by older writers to designate rocks now regarded as belonging to the norite type of Gabbro (q.v.).

Hypertrophy (Gr., 'over-nourishment') is the term applied in medicine to the enlargement of certain organs of the body. The best examples of this change are seen in the muscular system, where it may occur altogether independently of disease. The huge bosses of flesh that stand prominently forward in the arm of a blacksmith or of a pugilist, and in the leg of an opera-dancer, are illustrations of hypertrophy where the general health may be perfect. In double organs, such as the kidneys and lungs, if the organ on one side degenerates through disease, the organ on the opposite side is often found to enlarge and carry on double work. In these cases hypertrophy is an effect of disease, but is at the same time a resource of nature to preserve life. There are, however, cases in which the hypertrophy has a hurtful instead of a conservative effect, as, for example, hypertrophy of the thyroid gland, constituting the disease known as goitre or bronchocele, hypertrophy of the prostate gland, of the spleen, &c. The following are the conditions

which give rise to hypertrophy: (1) The increased exercise of a part in its healthy function; (2) an increased accumulation in the blood of the particular materials which a part appropriates in its nutrition or in secretion; (3) an increased afflux of healthy blood. In hypertrophy of the muscular tissue the first and third of these conditions are present. Hypertrophy of the fatty tissue constitutes Obesity (q.v.).

Hypnerotomachia, a notable product of the Aldine Press, is a quaintly erudite architectural romance in macaronic Latin, credited to 'Poliphilus,' but probably written by a Dominican, Francisco Colonna, who died an old man in 1525. The second edition was printed in 1545; it was Englished as early as 1592; edited by Andrew Lang; and reproduced in fac-simile in 1904.

Hypnotics. See NARCOTICS, SLEEP.

Hypnotism, a form of psycho-therapeutics, is discussed as to its nature and history, and the methods of inducing it, at Animal Magnetism (q.v.). Long tabooed as superstition by the medical profession, it is now very extensively used on the Continent and in America in treating disease, and the prejudice which was long felt against it in this country is diminished. Hypnotism is no longer to be regarded as a mystery or as a superhuman gift, for its action can, for the most part, be explained by our present knowledge of physiology and psychology. The chief reason why hypnotism cannot be universally employed as a therapeutic agent is the fact that only a certain proportion of persons are susceptible. It has been found that somnambulism, the deepest stage of hypnotism, is not necessary when the method is employed therapeutically, and waking suggestion is now largely used in treating disease; and it is asserted that about 90 per cent. of the inhabitants of this or any other country could if necessary be treated by hypnotism in the form of waking suggestion with every prospect of benefit.

Hypnotism may be used in two ways in relation to disease. In the first place, simple sleep is induced; and sleep when induced without the action of drugs is often of great importance, and of itself aids in treatment. Again, in many cases when the person is asleep suggestions may be made which will abolish pain, and which in many diseases will bring about either the relief of symptoms or the cure of the disease. As every one knows, the mind influences the body, and concentrated thought can bring about sensations in various localities. It is upon this knowledge that the hypnotist bases his practice. The patient being placed in a hypnotic sleep, his attention is directed to various parts of the body, and often the effect is increased through local stimulation by means of passes. During the hypnotic sleep the patient is uninfluenced by his surroundings, and is therefore all the more open to suggestions, and no disturbing influences diminish his powers of concentration. By means such as these neuralgic or rheumatic pains may frequently be removed; headaches may often be cured, and so may some forms of dyspepsia, as well as the various manifestations of hysteria and hypochondriasis, stammering, and even functional paralysis. Constipation is almost always benefited. Many diseases of women and various sexual troubles are susceptible of treatment, and hypnotism is a very useful method in treating persons suffering from dipsomania or addicted to drugs or other depraved habits. At present it cannot be said that hypnotism is of use in any disease having an organic origin, although in such diseases various symptoms, especially those of pain, may be removed successfully. Even operations may be performed upon persons under hypnotic influence without the slightest pain being felt by the patient; but as

various other anæsthetics are more easily employed, it is only in a few cases where these are contra-indicated that hypnotism is to be preferred.

For educational purposes it is possible to impress a person during hypnosis with ideas which will modify his usual character. For instance, it is possible in many cases to cure persons of bad habits such as stealing, lying, &c.; and on the Continent attempts to influence habitual criminals for good by hypnosis have proved largely successful. Young children affected in brain-power or constitutionally vicious may be greatly improved by careful hypnotic treatment. It is a mistake to suppose that hypnotism can only be used successfully in treating nervous or hysterical persons; such are often difficult, if not impossible, to hypnotise. Just ordinary individuals, especially those who have learnt to obey, are the subjects whom a hypnotist would prefer to treat. Children at school, soldiers and sailors, and officials of all ranks are the classes from which the most brilliant successes have hitherto been obtained in treating disease. In some cases of insanity hypnotism has been used with advantage as a therapeutic agent, but it is not easy to hypnotise the insane. Persons suffering from hallucinations have been cured, and those who suffer from the painful results of some grievous trouble have been restored by having the incident blotted out from their memory. Although hypnotism has a power for good when properly used by medical men, it is a dangerous weapon in the hands of the unskilful or the unscrupulous. All public exhibitions of hypnotism should be prohibited by law, as is the case in almost every Continental country. Just as a person when hypnotised is rendered extremely impressionable, and therefore capable of receiving beneficial suggestions, so he is also liable to receive suggestions for evil. Although it is true that as a matter of fact it is hardly possible to induce a person by hypnotic means to act against his settled convictions, still during hypnosis he will act for the time as an automaton. It is impossible for a person to be hypnotised unless he has the preconceived idea of what is going to happen. It is a psychical and not a physical influence which brings about the condition. Only persons whose will-power is weakened by fear or by the idea of a supposed power which influences them in spite of themselves can be hypnotised without full consent on their part; but the oftener the person is hypnotised, the more easily may he subsequently be affected. For this reason a wise hypnotist attempts to guard his patient by telling him during hypnosis that no one can hypnotise him without his own consent.

It will in general be readily admitted that we are indebted to the evolution of the theory of subconsciousness for a clearer conception of the causation of the hypnotic state. The essential characteristic of this condition is the extended power of the subject over his organism. This phenomenon arises from the voluntary modification in the association and dissociation of ideas which results in the clearer definition of subconscious impressions.

Hypnosis has proved to have limitations as a means of psychotherapy. Two methods of analogous treatment are now being largely used in America and on the Continent to which a brief reference must be made. Boris Sidis discovered an intermediate state between hypnosis and waking, which he termed the hypnoidal or sub-waking state. In this condition, which simply necessitates the patient being in a comfortable position in a quiet and dim room, suggestions may be readily impressed upon the mind. Sidis held that apart from the possibility of getting access to the subconscious experiences lost to the patient's personal consciousness, we may combine 'a syste-

matic course of direct and indirect suggestion by mediate associative and immediate associative, by substitution, disintegration, and synthesis, both in the waking and in the hypnoidal state,' which will transform the patient's mental life. He said that 'the hypnoidal state helps us to reach the inaccessible regions of dormant energy, helps to break down inhibitions, liberate reserve energies, and repair the breaches of mental activity; the painful systems become dissociated, disintegrated and again transformed, reformed and again reintegrated into new systems full of energy and the joy of life.' This method is extremely useful in treating persons who object to being hypnotised.

The so-called psycho-analysis of Freud is also very useful, but has the drawback of demanding a very great deal of time both from the physician and the patient. We may say that true psycho-analysis is not suggestion treatment, although, as in the production of the hypnoidal state, the same initial conditions of restful calm and dim light are essential. This method of treatment is 'an attempt to enable the patient to penetrate with tireless zeal and increasing skill and fearless honesty into the details of his own emotions, life, and thought, in the belief that nothing becomes less sacred, or fails to become less painful, through being clearly seen.' Freud believes that it is some long-forgotten, hidden concept which lies at the bottom of much nervous disease or mental instability. By long-continued, intimate conversation, and following up clues obtained therefrom, he is often successful in ascertaining the cause of the trouble and restoring the patient to health.

Hypnum, a genus of mosses belonging to the order Bryineæ. Archegonia and capsules are borne on special lateral branches. The sexual organs are formed in August and September, and the capsules take from ten months to a year to ripen. Many species are remarkable for their beauty, and are often used for decorative purposes. Their distribution is universal.

Hypocaust, a form of furnace used by the Romans for the purpose of heating baths and apartments. It was placed in a chamber beneath the floor, and the heated air and products of combustion were made to circulate round the walls and under the floor, and were also carried in pipes to other rooms. See BATHS.

Hypochaeris, a genus of Compositæ, sub-order Cichoraceæ, of which one species, *H. radicata*, or Long-rooted Cat's-ear, is extremely common in meadows and pastures in Britain. Its leaves spread on the ground, and are like those of the dandelion, but rough; the stem is branched, the flowers not unlike those of the dandelion, but smaller. Cattle eat this plant readily, and its abundance is not deemed injurious to pasture or fodder.

Hypochlorous Acid (HClO) can only be obtained as a dilute solution, as in the concentrated state it is very liable to decomposition. It is a powerful bleaching agent, and forms a series of salts, *hypochlorites*, which also possess bleaching properties. The chief of these are the hypochlorites of lime and soda. The lime salt is the important constituent of Bleaching Powder (q.v.), while the soda salt is prepared commercially by passing chlorine into a cold solution of soda.

Hypochondriasis (so called from its supposed connection with the hypochondriac regions of the Abdomen, q.v.), a disease characterised by extreme increase of sensibility, palpitations, morbid feelings that simulate most diseases, exaggerated uneasiness and anxiety, chiefly in what concerns the health, &c. In extreme cases it becomes a species of melancholia. The disease is intimately connected with disorder of the digestive

functions and allied to hysteria. See INDIGESTION, INSANITY.

Hypodermic Injection, first introduced in Britain by Dr Alexander Wood of Edinburgh, is an extremely valuable method in certain cases, though its applicability is limited. It consists in the injection of a solution of the substance to be given beneath the skin, by means of a fine hollow needle to which a small syringe is attached. The prick given by the needle is not felt by the patient if the needle be sharp and quite free from rust or roughness. Absorption from the subcutaneous tissues takes place speedily, and is not interfered with by vomiting, or other conditions of the stomach which may delay or prevent the entrance of the remedy into the system by that channel. The action of the drug is thus more rapid and more certain than when it is administered by the mouth; and a smaller dose is required. Only such substances as can be given in small bulk and in an unirritating condition are available. It is thus chiefly of use for the vegetable alkaloids, of which morphia is far the most often employed. It need hardly be said that it is to be used only by skilled hands. The same method is largely employed in experiments on the action of disease poisons in animals, and in the administration of vaccines, antitoxins, &c.; see also DIPHTHERIA, TUBERCLE.

Hypostasis, the Greek term used to designate the distinct subsistence of the three persons of the Trinity (q.v.).

Hypotenuse, the name of that side in a right-angled triangle which is opposite to the right angle. The well-known property of the hypotenuse, that the square described on it is equal to the sum of the squares described on the other two sides, is proved in Euclid's 47th proposition of Book I.

Hypothec, in Scotland a lien or security over goods in respect of a debt due by the owner. Thus, a law-agent or attorney has a hypothec over the title-deeds of his client in respect of his account or bill of costs; the landlord of urban subjects over the tenant's movables on the premises for the current rent; a superior in respect of feu-duties. There are also maritime hypothecs in respect of salvage, seamen's wages, &c. A hypothec in favour of the landlord of agricultural subjects was abolished in 1881. See LANDLORD AND TENANT.

Hyra, a genus of mammals representing a distinct order (Hyracoidea), the affinities of which are very obscure, and unilluminated by the few fossils that have been found. 'Feeble folk' as the species of hyrax (so-called 'cony') are, they find, according to many, their nearest allies in the huge elephants or in the ungulates proper. In size they are like rabbits; but the name 'cony', which really belongs to the rabbit, is not very appropriate; in appearance they rather suggest marmots. They are natives of

Hyrax syriacus.

Africa and Syria, and live among the rocks, in stony deserts, or on trees. The plump body, thick head, small ears, short slender limbs, rudimentary tail, soft yellowish-gray or brownish fur are obvious external characteristics. Closer examination shows many peculiarities. The snout, which has a cleft upper lip, is somewhat rodent-like, and so are the rootless, persistently growing

curved upper incisors, except that they have a prismatic shape and a sharp point instead of the chisel edge of rodents. The entire dentition is expressed in the formula $\frac{1113}{1113}$, and the back teeth are in pattern distinctly like those of the rhinoceros and some other ungulates. There are four toes on the anterior limbs, three on the hind, all with short broad nails except the inner toe of the hind-foot, which bears a curved claw. The feet strikingly suggest those of rhinoceros or tapir, and are interesting in the further peculiarity that the naked sole is furrowed in such a way that the hyrax can in gecko-like fashion cling to the vertical sides of rocks and trees. Among the many characteristics of the skeleton may be noticed the large number (28-30) of back and loin (dorso-lumbar) vertebrae. The brain and skull most resemble those of ungulates; the stomach recalls that of horse or rhinoceros; the placenta is zonary as in elephants and carnivores.

There are fourteen species, sometimes referred to two genera, Hyrax (or Procavia) and Dendrohyrax. The former is represented by *H. capensis*, the Cape Daman, Klipdas, or Rock-badger; *H. syriacus*, the Shaphan—mistranslated 'cony'—of Scripture; and *H. habesinicus*, the Ashtok of the Abyssinians. These live in companies, usually in holes among the rocks, and feed on shoots, grass, flowers, and the like. In reference to the Scripture account it may be noted that the hyrax does *not* chew the cud, though it moves its jaws very constantly. Though only two are born at a birth, the rate of multiplication is very rapid, keeping pace with ravages of carnivores, which are very deadly in spite of the caution and even sentinels of the hyraxes. Of different habitat, and sometimes referred to the second genus, Dendrohyrax, are certain hyraxes which, in West and South Africa, live in trees—e.g. *D. arboreus* and *D. dorsalis*. The members of this order, so puzzling zoologically, are playful, good-humoured, and wary. Their flesh is sometimes eaten, and is said to resemble rabbit's.—*Hyraecum*, a supposed medicine for certain nervous diseases, was made from the mixed urine and faeces of the Cape Hyrax.

Hyrcania, an ancient district of Asia, of indefinite extent, bordered on the Caspian Sea (sometimes called *Hyrcanum Mare*) and the river Oxus. It corresponded with the modern Mazanderan and Asterabad.

Hyrcanus, the name of two Jewish high-priests and princes of the Hasmonean family (see MACCABEES). (1) JOHN HYRCANUS, son of Simon Maccabæus, who ruled 135-105 B.C., was at first tributary to the Syrians, but on the death of Antiochus made himself independent, subdued the Samaritans on the north, and forced the Idumæans on the south to adopt the laws and customs of the Jews. He also concluded an alliance with the Romans, and extended his territories almost to the ancient limits of the Davidian monarchy. Originally a Pharisee, he subsequently attached himself to the party of the Sadducees, who were anxious to keep on good terms with the Romans, and who discountenanced the turbulent religious patriotism of the Jewish masses. Hyrcanus was, comparatively speaking, a just and enlightened ruler, and the country enjoyed great prosperity during his reign. He left five sons, two of whom, Aristobulus and Alexander, governed with the title of king.—(2) HYRCANUS II., son of Alexander, and grandson of the preceding, was a feeble prince. On the death of his father (78 B.C.) he was appointed high-priest by his mother Alexandra, who ruled Judæa herself for the next nine years. After her death (69 B.C.) his younger brother, Aristobulus, a braver and more energetic

man, seized the government, and forced Hyrcanus to withdraw into private life. He failed to win back his dominions, until Pompey began to favour his cause. After some years of tumultuous fighting, Aristobulus was poisoned by the partisans of Ptolemy (49 B.C.), and Hyrcanus for some time possessed the dignity of high-priest. Cæsar (47 B.C.), on account of the services rendered to him by Antipater of Idumæa, made the latter procurator of Judæa, and thus left in his hands all the real power. Antipater was assassinated, and Antigonus, son of Aristobulus, with the help of the Parthian king, invaded the land, captured Hyrcanus by treachery, cut off his ears, and carried him off to Seleucia on the Tigris. Some years later Herod, son of his old friend Antipater, obtained supreme power in Judæa, and invited the aged Hyrcanus home to Jerusalem. He was allowed to depart, and for some time lived in ease and comfort; but, falling under suspicion of intriguing against Herod, he was put to death, 30 B.C.

Hyslop, JAMES, poet, was born in the parish of Kirkconnel, Dumfriesshire, 23d July 1798. He was a shepherd near Airdsmoss, Ayrshire, the scene of a Covenanting skirmish and Cameron's death (1680), and the traditions of the district inspired his best-known poem, 'The Cameronian's Dream,' which appeared in the *Edinburgh Magazine* (1821). He studied privately, and through the influence of Lord Jeffrey was appointed tutor on board the *Doris*. While tutor on board the *Tweed* man-of-war he died of fever at St Jago, Cape Verde Islands, 4th November 1827. An edition of his poems was printed from his manuscript book by the Rev. P. Mearns (Glasg. 1887). Mr Hamish McCunn set his 'Cameronian's Dream' to music in 1889.

Hyssop (*Hyssopus officinalis*), a plant of the natural order Labiatae, distinguished by four straight diverging stamens, and a calyx with fifteen ribs. It was formerly used in medicine. It is a native of the south of Europe and the East. It is found on the Alps. It is a half-shrubby plant, about 1½ feet high, the upper part of the stems quadrangular, the leaves evergreen and lanceolate, the flowers in one-sided whorled racemes. The flowers are generally of a very beautiful blue. It has an agreeable aromatic odour. It has long been in cultivation for the sake of its leaves and young shoots, which are sometimes used as a seasoning, and were once used in a dried state as a stomachic and carminative. A syrup made with them was a popular remedy for colds. The virtues of hyssop depend on a volatile oil. The hyssop of the Bible has been supposed to be some species of the kindred genera *Satureia* and *Origanum* (see MARJORAM), or of *Phytolacca* (q.v.), as *P. acinosa*, a native of the Himalaya; or by others the common Caper (q.v.); but all this is pure guesswork. Rabbinical tradition points to *Thymus capitatus* as the plant intended (Exodus, xii. 22), and the Jews of Palestine so use it. — Hedge Hyssop is *Gratiola officinalis*. See GRATIOLA.

Common Hyssop
(*Hyssopus officinalis*)

it. — Hedge Hyssop is *Gratiola officinalis*. See GRATIOLA.

Hysteria is a morbid mental condition manifesting itself by symptoms which it is possible to reproduce by suggestion in certain subjects with a perfect exactitude, and which it is also possible to remove by counter-suggestion or other methods of psychotherapy. As it is universally diffused among all the races of mankind, civilised and uncivilised, it is one of the commonest neuroses. Some authorities assert that symptoms indicative of it have been observed among the higher animal species other than man. It used to be regarded as a malady almost exclusively confined to the female sex, but recent experience of war neuroses and other facts have shown this opinion to be erroneous.

Within recent years the writings of Charcot, Janet, and Freud have greatly enlarged our knowledge of the mechanism of the production of hysteria. These theories, elaborated by Freud and his disciples, may be stated briefly as follows:

The individual 'self' strives simply and unservedly to satisfy egoistic instinctive tendencies. Opposed to this selfish proclivity there is developed in every normal individual a social ideal which aims at self-control. The wish of the individual 'self' to satisfy the instinctive tendencies is not compatible with the ideal of the social 'self,' and the contest between the two gives rise to mental conflict.

The discomfort produced by this conflict is removed by the repression of the complex into the unconscious. If the social ideal is sufficiently strong, it overcomes the instinctive impulses, which with their associations form the complex, and diverts their energies into various useful channels; but if the social 'self' has not been properly developed, or if it has been weakened by illness or prolonged emotion, repression is incomplete, and the partially repressed, painful complex may remain active, and be harmful to mental health. At any time, as the result of an accident, illness, or emotional shock, this imperfectly repressed complex may assume pathological activity, and express itself indirectly and symbolically in the physical symptoms of hysteria. In this way a compromise is formed between the social ideal and the complex, and in this way also a solution of the conflict is found.

In other words, and in terms of the older theories, the symptoms of hysteria are due to a combination of predisposing and exciting causes. The most important predisposing causes are hereditary mental instability and the influence of the home environment on the child during its development. The formation of character and temperament may be impaired by association with timorous or too indulgent or cruel parents, and harmful experiences in early life may lay the foundation of the hysterical disposition. The exciting cause is usually a severe emotional shock, an accident, a fright, a reverse of fortune, or an unhappy love affair.

It is well known that in mentally unstable individuals emotional crises like fear, anxiety, or shock have a tendency to dissociate the mental organisation in such a way that normal associations become severed or loosened. Arising from this dissociation or severing of sensory, motor, or other images from the main stream of consciousness, there are apt to occur loss of sensation in various parts of the body, paralysis of a limb, functional blindness, deafness, loss of speech, and loss of memory (amnesia). In other instances, when the dissociation produced by the emotion is more general, there appear pains, headaches, prostration, rapid beating of the heart, and digestive disturbances.

Now, the foregoing are all prominent among the numerous physical symptoms of hysteria.

On the mental side the chief symptoms are moral perversion, largely due to a morbid craving for

sympathy and notoriety; uncontrolled conduct, which reveals itself in yielding to unregulated whims and impulses; and mimicry. There is hardly any nervous disease the appearance of which the patient may not simulate. The process is often so successful that, as a rule, the patient not only succeeds in deceiving himself, but also those with whom he is associated.

In addition to the innumerable physical and mental symptoms referred to above in general terms, there are occasional convulsive seizures which, in the popular mind, are chiefly associated with hysteria. In the milder forms of the fit there is no loss of consciousness, but the arms, legs, and head are tossed about, and there is great mental excitement. In severer fits, perhaps after some premonitory symptoms, such as the sense of constriction in the throat known as the *globus hystericus*, the patient falls to the ground, sometimes with a scream, the features twitching, the back arched, and the arms and legs moving convulsively. They rarely hurt themselves in falling, as often happens in the case of epileptics. The seizure may last a few seconds or several hours.

The treatment of hysteria must be directed both to the cure or alleviation of the symptoms and the removal of the condition which gives rise to them. The first object can generally be attained, the second more rarely. It must be remembered that, as in other neuroses, there is often an underlying constitutional or early acquired defect of which the symptoms are the critical phenomena, and there is always a tendency to a recurrence or periodic recrudescence of the symptoms. But even in those cases in which periodicity has become established, the tendency ceases with advancing years.

In the treatment of all hysterical cases a complete change of the environment is essential, and of itself is sometimes sufficient to remove the symptoms. The patient should be placed among strangers, and away from sympathising friends; the doctor must secure the patient's confidence; the nurse must be kind, though firm; and the patient must be encouraged to exercise self-control.

In early recent cases the symptoms may yield to general suggestion of this kind, or to more direct persuasion and suggestion applied to the existence of specific symptoms. In chronic cases, however, the more elaborate methods of psychotherapy may be necessary.

In view of what has been said as to the origin

of hysteria, it will be appreciated why the use of drugs and other forms of treatment have fallen into disuse, except in so far as they are employed as adjuvants to psychotherapy. Much benefit is, however, derived in certain cases from the judicious use of massage and special feeding in the form of what is known as the Weir-Mitchell treatment.

Hystrix. See PORCUPINE.

Hythe, a parliamentary and municipal borough and market-town of Kent, 5 miles WSW. of Folkestone, 15 miles S. of Canterbury, and 67 SE. by E. of London by rail, is one of the Cinque Ports (q.v.), although in actual locality Lympne or Lymm (the ancient *Portus Lemani* of the Romans), now some 3 miles inland, was probably the original harbour. The town, which is pleasantly situated some distance from the sea, is built on the side of a hill, from the top of which an extensive view over the Romney marsh is obtained. Its church, a cruciform building of great beauty, in part Romanesque, has been restored since 1866, and contains in a crypt underneath the chancel an extraordinary collection of human skulls and bones—many of the skulls having deep cuts in them—the age and origin of which are altogether uncertain. Near to Hythe are the headquarters of the School of Musketry and Shorncliffe camp, both established in 1854; the picturesque ruins of Saltwood Castle, with memories of Becket; and the Royal Military Canal, 23 miles in length, constructed in 1805 for the conveyance of military stores to Rye, but never of much use, and now entirely superseded by the railway. In 1881 a sea-wall and parade, extending from Hythe to Sandgate (q.v.) and Folkestone (q.v.), was opened. These and Cheriton urban district are included in the parliamentary borough of Hythe, which since 1832 has returned only one member. Pop. of that borough (1851) 13,164; (1921) 54,573, of whom 7764 were within the municipal borough, which includes West Hythe.—In 1295 the French made a descent on Hythe, but were decisively repulsed; and later on, towards the end of the reign of Richard II., the town was visited with a threefold calamity, a fire having destroyed 200 houses, a pestilence carried off numerous inhabitants, and an unusually heavy storm caused a severe loss of men and ships. Several charters are preserved at Hythe, amongst them its earliest charter of incorporation granted in 1575. See Montagu Burrows' *Cinque Ports* (1888).

I

the ninth letter of the English, Roman, and late Greek alphabet, descends from the tenth letter of the early Greek and Semitic alphabets. The difference in numerical position is due to the fact that the Romans did not adopt the ninth Greek letter, *thēta*, while the late Greeks

dropped the original sixth letter (see F). The Semitic letter represented primarily the consonant *y*, and secondarily the cognate vowel *ī* (= *i* in *machine*). Its name, in Hebrew *yōdh*, in Syriac *yūdh*, probably was in some early dialect *yōda*, which the Greeks changed into *ōda*, by assimilation to the names of the preceding letters (*h*)*ēta* and *thēta*. The name seems to be an alteration of the Semitic word for a hand (Hebrew *yōdh*, Arabic *yad*), and it is conceivable that the earliest form of the letter, , might have been developed from a

figure intended to represent a hand. From this primitive form, through successive modifications, the Hebrew *y* is derived. In early Greek inscriptions the letter appears in various zigzag and curved forms, but ultimately these gave place to the upright straight line, *l*. As the Greek language did not possess the sound of *y* (the voiced front open consonant), the letter was used only for the closely related high-front vowel, both long and short. The Romans, however, used *l* not only for the vowel, but also for the consonant or semi-vowel, the two related sounds in Latin having a tendency to interchange. Thus, while in *iam* the letter was pronounced as the consonant *y*, in the compound *etiam* it was a vowel. Although the ancient grammarians recognised that the letter had the two phonetic values, no consistent attempt was made to distinguish them in writing. It is true that the consonantal sound was sometimes indicated by prolonging the *l* above the line, or (in the middle of a word) by doubling it; but the former device was also sometimes used to denote the long vowel. The history of the letter as a consonant-symbol will be treated in the article on *J*, which is its modern representative in this function.

As a vowel-letter, *I* has retained its Roman sound (the high-front vowel) in all the languages that have inherited or adopted the Roman alphabet, with the partial exception of English and Dutch. In English until the 16th century the letter, when representing a long vowel, has still its Latin sound (= *ee* in *seen*, or *i* in *machine*); thus *time* was pronounced like the modern English *teem*. In consequence of gradual changes of pronunciation, the normal English long sound of the letter (as in its alphabetic name) is now a diphthong, resembling, but not quite identical with, the ancient Latin sound of *ai*. In a few words of foreign origin, as *machine*, the letter has its original long sound. In Dutch the original long vowel, written *ii* and afterwards *ij*, underwent nearly the same change as in English, so that the pronoun *mijn* is pronounced approximately like its English equivalent *mine*. The corresponding sound-change in German has not affected the phonetic value of the letter, because the spelling has been changed; e.g. the older *mīn* is now written *mein*.

The high-front vowel, of which *I* is the general European symbol, has two varieties, distinguished by phoneticians as 'narrow' (or 'tense') and 'wide'

(or 'slack'). In English, and in most of the Germanic dialects, the narrow sound occurs exclusively (or nearly so) as long (e.g. in *seen*, *machine*), and the wide sound exclusively as short (e.g. in *pit*); in French the vowel is always narrow. In Dutch the short *i* has acquired a lowered pronunciation, so that *winkel* sounds to an English ear like 'venkel.' In several languages the letter has exceptional values in certain positions, owing chiefly to changes in pronunciation not accompanied by changes in spelling. Thus in English words like *nation*, *vision*, the *ti*, *si* have become digraphs for the simple consonants *sh*, *zh*; the French *ai*, *ei*, *oi*, and the English *ui* in *fruit*, contain no *i* sound; and the French *i* before a vowel is often sounded *y*, as is also the English *i* in words like *onion*.

The mediæval practice of distinguishing capitals by added flourishes, and the preference for curves to straight lines natural in writing on soft materials, sufficiently account for the transformation of the Roman *l* into the modern script and black-letter capitals. The dot over the small *i*, *z*, represents a mark like an acute accent, which from the 11th century was used to distinguish the letter from one of the component strokes of *u*. In mediæval handwriting, such a word as *convivium*, with the letters joined, would have been almost illegible without this device.

Iago. See JAMES and SANTIAGO.

Iambic Verse, a term applied, in classic prosody, and sometimes in English, to verses composed of the foot or metre called *Iambus*, consisting of two syllables, of which the first is short, and the second long (—), or (in English) the first unstressed and the second stressed. Archilochus (q.v.) is the reputed inventor of iambic verse. The English language runs more easily and naturally in this metre than in any other.

Iamblichus, a Neoplatonist philosopher, a native of Chalcis, in Coele-Syria, who died about 330 A.D. He was a pupil of Porphyry, and follower of Plotinus; but in his hands the Neoplatonist philosophy degenerated into theurgy and demonology, while among his disciples his reputation spread as a conjurer and miracle-worker. His writings included a life of Pythagoras, and treatises on mathematics and philosophy; the authenticity of the treatise on Egyptian mysteries (ed. Parthey, 1857) is more than dubious. See NEOPLATONISM.

Ianthina, a genus of pelagic gasteropods, with a delicate, translucent, bluish shell. The animals

Common 'Violet Snail' (*Ianthina fragilis*):
Shell, animal, and raft.

float, 'foot' upwards, often gregariously on the surface of warmer seas, and are sometimes drifted on to British shores. The egg-capsules are attached

to the under side of a secreted buoyant raft or float, which is eventually set free. In many cases the 'Violet Snails' are found associated with Siphonophora, on which they seem to feed. They exude a violet secretion.

Ibáñez. See BLASCO IBÁÑEZ.

Ibarra, capital of Imbabura province, Ecuador, has a population of about 5000.

Iberia, the name by which Georgia (q.v.) was known to the Greeks and Romans; and also an ancient name for Spain. The question of an Iberian race is discussed at BASQUES.

Iberis. See CANDYTUFT.

Ibex, a name given to several species of the genus Capra, of which the best known is the Alpine Ibex (Ger. *Steinbock*, Fr. *Bouquetin*). The various species are described at GOAT.

Ibis, a genus of birds related to the Spoonbills, and, more remotely, to the Storks and Herons. It comprises about twenty-five species, of which the bulk belong to the Old World, though the genus is nearly cosmopolitan. The bill is long, slender, curved, thick at the base, the point rather obtuse, the upper mandible deeply grooved throughout its length. The face, and generally the greater part of the head, and sometimes even the neck, are destitute of feathers, at least in adult birds. The plumage is mainly white, with black primary feathers and plumes on the wings. The neck is long. The legs are rather long, naked above the tarsal joint, with three partially united toes in front, and one behind; the wings are moderately long; the tail is very short. The Sacred Ibis, or Egyptian Ibis (*I. aethiopica*; formerly known as *I. religiosa*), is an African bird, 2 feet 6 inches in length, although the body is little larger than that of a common fowl. The Glossy Ibis (*I.* or *Plegadis falcinellus*) is a smaller species, also African, but migrating northwards into continental Europe, and occasionally seen in Britain. It is also a North

The Sacred Ibis (*Ibis aethiopica*).

American bird—black, varied with reddish-brown, and exhibiting fine purple and green reflections. The White Ibis (*I. alba* or *Eudocimus albus*) abounds on the coasts of Florida. The Scarlet Ibis (*I. rubra* or *Eudocimus ruber*), a tropical American species, has only a few patches of glossy black. The Straw-necked Ibis (*I.* or *Carphibis spinicollis*), a large Australian bird of fine plumage, has stiff naked yellow feather-shafts on the neck and throat.

The Sacred Ibis, one of the birds worshipped by the ancient Egyptians, was supposed, from the colour of its feathers, to symbolise the light and shade of the moon, was the avatar of the god Thoth or Hermes, and was said to deliver Egypt from the winged and other serpents which came from Arabia. As it did not make its nest in Egypt, it was believed to be self-engendering. It was fabled to entertain the most invincible love of Egypt, and to die of self-starvation if transported elsewhere. To kill them was punishable with death; they were kept in temples, and at death were mummied.

Ibn. See BEN.

Ibn Batuta (properly Abu Abdullah Mohammed), born at Tangiers in 1304, spent thirty years (1325-54) of his life in travel—to Mecca, Persia, Mesopotamia, Arabia, the east coast of Africa, Asia Minor, the Caspian regions, Bokhara, Afghanistan, India, Sumatra, and China; returning home to Fez in 1349. Later he visited southern Spain, and went as far south as Timbuktu on the Niger. Settling at Fez in 1354, he wrote the history of his journeys, and died there in 1378. His narrative is extremely interesting, humour and anecdote alternating with graphic description. It was published with a French translation, in 4 vols. 1855-59; 3d ed. 1893.

Ibn Gabirol. See AVICEBRON.

Ibn Ezra. See ABEN-EZRA.

Ibrahim Pasha (1789-1848), viceroy of Egypt, born at Kavala, was an adopted son of Mehemet Ali. In 1825-27 he occupied the Morea against the Greeks. In 1832 he routed the Ottoman army at Konieh, after which the Porte ceded Syria to Mehemet Ali on condition of tribute—a session terminated through the quadruple alliance of 1840. In 1848 he succeeded Mehemet Ali (become imbecile) for a few months. See EGYPT.

Ibrail. See BRAILA.

Ibsen, HENRIK, Norwegian dramatist, was born at Skien, in southern Norway, March 20, 1828. His family, originally Danish, had been settled in Norway for about a century; and there were also Scotch and German strains in his ancestry. When the boy was eight years old, his father sank from affluence into poverty. At the age of fifteen, after a somewhat scanty education, he was apprenticed to an apothecary in the little town of Grimstad, where he remained for seven years. The political events of 1848 in France, Hungary, and Denmark elicited from him a number of poems full of revolutionary ardour; and an unsuccessful revolutionist, *Catiline*, was the hero of his first play, published, at a friend's expense, in 1850. In that year he came to Christiania, proposing to study medicine at the university; and here he made the acquaintance of his great contemporary Bjørnstjerne Bjørnson. Soon after his arrival in the capital he wrote a one-act sentimental tragedy, *The Warrior's Barrow*, which was produced with small success. His poverty was extreme; and some journalistic ventures in which he took part did little to relieve it. In November 1851 he became 'theatre poet' and 'scene instructor' in the Bergen Theatre, founded in 1850 by Ole Bull. This post he occupied for six years; and for the Bergen Theatre he wrote a romantic comedy, *St John's Night* (1853), a melodramatic tragedy, *Lady Inger of Ostrat* (1855), and two romantic plays, *The Feast at Solhoug* (1856) and *Olaf Liljekrans* (1857). He returned to Christiania in 1857, and during the next seven years led a life of bitter poverty and struggle, bravely shared by his wife, Susanna Daae Thoresen, whom he married in 1858.

To this period belong his first mature works, a legendary tragedy, *The Vikings at Helgeland* (1858); *Love's Comedy*, a social satire in rhymed verse (1862); and a superb historic drama, *The Pretenders* (1863). A small 'travelling stipend' allotted him by the government enabled him to leave Norway in 1864, and the early summer of that year found him in Rome.

In the first glow of his impressions of Italy, he planned a drama on the subject of Julian the Apostate, but soon postponed the idea in order to express his indignation at what he considered the pusillanimity and hypocrisy of the Norwegian character. *Brand* was begun as a narrative poem; but he presently abandoned that form, and produced in 1866 the great drama in verse which made him famous throughout Scandinavia. It was followed in 1867 by *Peer Gynt*, not so immediately popular, but certainly the greater work. The success of these two dramatic poems relieved him from the pressure of poverty; and his life was thereafter serene and prosperous, its only notable events being the production of play after play, and the removal of his headquarters from Rome to Dresden (1868), from Dresden to Munich (1875), from Munich back to Rome (1879), then again to Munich (1885), and finally to Christiania (1892). In 1869 he produced his first modern play in prose, that lively comedy *The League of Youth*. It met with a stormy reception on the stage, and led to an estrangement from Björnson, which was not healed until twelve years later. A long pause preceded his next production, the 'world-historic drama' in two parts, *Emperor and Galilean*. Then, again, four years passed before, in 1877, he issued *Pillars of Society*. Thenceforward, until 1896, his plays, with one exception, succeeded each other at intervals of two years. The exception was *An Enemy of the People*, inspired by his indignation over the reception of *Ghosts*, and produced in a single year. The dates are as follows: *A Doll's House* (1879), *Ghosts* (1881), *An Enemy of the People* (1882), *The Wild Duck* (1884), *Rosmersholm* (1886), *The Lady from the Sea* (1888), *Hedda Gabler* (1890), *The Master Builder* (1892), *Little Eyolf* (1894), *John Gabriel Borkman* (1896). Then ensued an interval of three years before he produced, in 1899, his last work, *When We Dead Awaken*. Early in 1901 his health broke down, and, after a sad period of decrepitude, he died on May 23, 1906.

Ibsen's career may be divided into five periods, which naturally shade off into each other, and yet are pretty clearly distinguishable. (1) The Romantic Period, extending from his first efforts to *The Pretenders*. Here he is influenced by Danish romanticism (Oehlenschläger and Hertz), by Norwegian national-romanticism, and (technically) by the French romanticism of the elder Dumas and of Scribe's quasi-historic dramas. (2) The Satiric Period, which overlaps the Romantic Period, inasmuch as *Love's Comedy* preceded *The Pretenders*. It extends from *Love's Comedy* to *The League of Youth*, and thus includes *Brand* and *Peer Gynt*. The poet is mainly concerned with castigating the pettiness, insincerity, and spirit of compromise which he finds to be characteristic of his countrymen. (3) The Philosophic Period, of which a foretaste may be found in *The Pretenders*, but which extended from 1870 to 1877, and has for its chief production (apart from some lyric poems) the double drama, *Emperor and Galilean*. During this period he went through a course of mental development, largely influenced by the Franco-German war, and arrived at full intellectual maturity. (4) The Realistic Period, which extends from *Pillars of Society* to *An Enemy of the People*. Here he is attempting to express his criticism of life in downright everyday prose, and to hold his

imagination as much as possible in check. (5) The Imaginative Period, extending from *The Wild Duck* to the end of his life, and toning off, from *The Master Builder* onwards, into what may be called the Symbolic Sub-period. More and more, during this period, his imagination gets the upper hand of his sense of literal reality, and he infuses into his pictures of life an element of poetry which gives them a strange and haunting fascination. In three plays (*The Lady from the Sea*, *The Master Builder*, and *Little Eyolf*) he even dallies with the 'occult,' though without positively committing himself to the reality of its alleged manifestations. The three main qualities in which the greatness of Ibsen resides are his superb gift of imagination and invention, his searching criticism of life from an ethico-psychological standpoint, and the novel and masterly dramatic technique which he developed in his later works. He may fairly be said to have revolutionised the methods of the modern stage.

All Ibsen's plays except *Catiline*, *The Warrior's Grave*, *St John's Night*, and *Olaf Liheltrans* are translated into English and published in a collected edition (London, Heinemann; New York, Scribner). A supplementary volume, *From Ibsen's Workshop*, contains scenarios and first drafts of his modern plays. Important Norwegian editions are those edited by Storm (1906) and by Seip (1918). The standard German edition is that edited by Brandes, Elias, and Schlenker (1903). La Chesnais's French edition promised to be the most complete and scholarly of all, but was interrupted by the war. Jaeger's Life of Ibsen (English translation, 1890) has been superseded by Gran's (1918), which is not yet translated. See also the biography by Edmund Gosse, who first introduced Ibsen to English readers, and *The Correspondence of Henrik Ibsen*, translated by Mary Morison (1905). George Brandes's *Ibsen and Björnson* (translated 1899) holds a place apart among criticisms on account of the critic's lifelong intimacy with the poet. The British Museum catalogue enumerates twenty-two English and American books relating to Ibsen, twenty-seven Norwegian and Danish, nine Swedish, forty-three German, twelve French, eight Italian, seven Dutch, two Russian, one Czech, and one Portuguese. Among the more notable commentaries may be mentioned (in English) those by Philip Wicksteed, Bernard Shaw, Ellis Roberts, James Huneker, and Archibald Henderson, and (in German) those by L. Berg, O. Brahm, A. von Hanstein, B. Litzmann, E. Reich, E. Steiger, and R. Woerner.

[It is principally due to Mr William Archer, writer of the above article, that Ibsen's plays have become so widely known in England and America. He has translated the greater number of the plays and assisted in the production of those that have been performed on the London stage. He has also edited the collected works of Ibsen in English (11 vols.), each play being furnished with a biographical introduction and critical remarks.—ED.]

Ibycus, Greek lyric poet, a native of Rhegium, in Italy, flourished about 540 B.C., and lived some time at the court of Polycrates, tyrant of Samos. According to the legend he was slain by robbers near Corinth, and dying called upon a flock of cranes that he saw flying overhead to avenge him. The cranes went and hovered over the theatre at Corinth, where the people were assembled. One of the murderers, seeing them, exclaimed involuntarily, 'Behold the avengers of Ibycus.' This led to inquiry and conviction. The story is best told in Schiller's beautiful ballad. Ibycus wrote chiefly erotic poetry. For surviving fragments, see Bergk's *Poetae Lyrici Graeci* (vol. iii.); Schneidewin's *Delectus Poesis Graecorum Elegiacae* (1839); Grenfell and Hunt, *Oxyrhynchus Papyri*, xv. (1922).

Ica, a department on the coast of Peru, with an area of 8000 sq. m. and a pop. of about 90,000. The greater part is a sandy desert, but the river-valleys are fertile, and are planted with corn, fruits, cotton, and indigo. In one of these valleys lies the capital, Ica, 46 miles SE. of Pisco, its port, with which it is connected by railway. Pop. 15,000.

Icarus. See DÆDALUS.

Ice is water in the solid form. It is specifically lighter than water which is just about to freeze, and therefore swims in it. Water, in becoming solid, expands about $\frac{1}{11}$ th in volume or bulk, and thus acquires a density equal to 0.91674 (water at 0° C. = 1.00). The formation of ice takes place generally at the surface of water. This is owing to the peculiarity that, when water has (at the ordinary atmospheric pressure) cooled down to within 3.9° C. of freezing, it ceases to contract as it did before with increase of cold, and begins to expand until it freezes (see HEAT); this causes the coldest portions of the water to be floating always on the surface. In some circumstances, not very well explained, ice forms at the bottom of rivers, and is called ground-ice or Anchor-ice (q.v.).

Water in ordinary cases freezes at the degree of temperature marked 0° on the Centigrade and Réaumur's thermometers and 32° on Fahrenheit's; but if it is kept perfectly still it may be cooled to nearly -5.5° C. below freezing (= 22° F.) and still remain liquid. The least shake, however, or throwing in of a solid body, makes a portion of it freeze instantly, and its temperature rises immediately to 0° C. Sea-water, and salt water in general, freezes at a lower temperature than pure water; in doing this part of the salt separates, and the ice, when melted, gives water that is fresher than that on which the ice was formed. The colour of pure ice is deep blue, which is only discernible, however, when it is in large masses; it is best seen in the clefts of a glacier or of an iceberg. In order to melt a pound of ice it is necessary to communicate to it as much heat as will raise 80.025 lb. of water 1° C. This measures the 'latent heat' of ice; the temperature does not rise until the ice has been melted.

In the neighbourhood of the poles, and on mountains of a certain height in all latitudes, there exist immense masses of permanent ice; and even in some districts of Siberia, where a kind of culture is practicable in summer, there are found, at a certain depth below the surface of the earth, strata of ice mingled with sand. In sinking a well at Yakutsk, the soil was found permanently frozen

An Iceberg,
showing the proportion under water.

hard to the depth of 382 feet, and consisting in some parts entirely of ice. In the lower regions of the torrid zone there is no ice, and in the temperate zones it is a passing phenomenon. From the polar icefields and glaciers which are always protruding themselves into the sea, great floating masses become detached and form *icebergs*, flocs, and drift-ice (see GLACIER). These bergs or mountains

of ice rise sometimes more than 250 feet above the sea-level. They present the appearance of dazzling white chalk-cliffs of the most fantastic shapes. Fresh fractures have a green or blue colour. From the specific gravity, it is calculated that the volume of an iceberg below the water is about nine times that of the protruding part. Icebergs, and flocs or icefields, are often laden with pieces of rock and masses of stones and detritus, which they have brought with them from the coasts where they were formed, and which they often transport to a great distance towards the equator. These floating masses of ice are dangerous to navigation. The *ice-foot* is the belt or fringe of ice along the shores in polar regions.

The hardness and strength of ice increases with the degree of cold. In the severe winter of 1740 a house was built of the ice of the Neva at St Petersburg, 50 feet long, 16 wide, and 20 high, and the walls supported the roof, which was also of ice, without the least injury. Before it stood two ice-mortars and six ice-cannon, made on the turning-lathe, with carriages and wheels also of ice. The cannon were of the calibre of 6-pounders; the thickness of the ice was only four inches, and yet it resisted the explosion.

Faraday first called attention to a remarkable property of ice, since called Regelation. Two slabs of ice, with flat surfaces, placed in contact, unite into one mass even though the temperature of the surrounding air be considerably *above* the freezing-point. Faraday endeavoured to account for this by assuming that a small quantity of water, surrounded on every side by ice, has a natural tendency to become ice; and the fact that two blocks of ice placed in contact do not unite unless they are *moist* seemed to bear out this idea. But J. Thomson gave a totally different explanation of this phenomenon. He showed that the capillary force in the film of water between the plates is sufficient to account for a very considerable pressure between them; so that from his point of view the phenomenon would be identical with the making of snowballs by pressure, or with the formation, by a hydraulic press, of clear blocks from a mass of pounded ice, an observed fact, the explanation of which is to be found in the property of ice mentioned below. Faraday, taking up the question again, showed that the (so-called) regelation takes place in *water* as readily as in air, a fact quite inconsistent with the action of capillary forces. To this J. Thomson replied, showing, very ingeniously, that the capillary forces he at first assumed are not necessary to a complete explanation of the observed phenomena. See *Proc. Roy. Soc.*, 1860-61.

Other views of the question are numerous: for instance, that of Persoz, adopted by Forbes, in which ice was considered as essentially colder than water, and as passing through a sort of viscous state before liquefying, as metals do during the process of melting. This idea, however, has not found much, if any, support; and it is possible that the true solution of the question is, as J. Thomson pointed out, to be found in the analogy of the crystallisation of salts from their aqueous solutions.

However that may be, there is no doubt about the following property of ice, theoretically predicted by J. Thomson from the experimental fact of its expanding in the act of freezing, and demonstrated by means of the Piezometer by his brother Lord Kelvin—viz. that the freezing-point of water, or the melting-point of ice, is *lowered by pressure* to the extent of 0.0074° C. for every atmosphere of pressure; and the brothers, with singular ingenuity, applied this to the explanation of the motion of glaciers. That a mass of glacier-ice moves in its channel like a viscous fluid was first completely established by Forbes. The explanation given of

this motion is of the following nature: In the immense mass of the glacier (even if it were homogeneous, much more so when full of cracks and fissures, as it always is) there are portions subjected to a much greater stress than others. The pressure to which they are subjected is such as corresponds to a melting-point considerably *below* the temperature of the mass—and therefore, at such points, if the ice be not altogether too cold it melts, the stress is relieved, and the whole mass is free for an instant to move nearly as a fluid would move in its place. But, the stresses being thus for an instant removed, the temperature and pressure of the water are again consistent with freezing—the thin layer of water quickly solidifies, and then matters proceed as before. Thus, at every instant, the stresses at different parts of the mass melt it at those places where they are greatest, and so produce the extraordinary phenomenon of a mass which might in common language be termed *solid*, and even *rigid*, slowly creeping down its rocky bed like a stream of tar or treacle. This explanation would not meet the case of extremely cold ice; and it appears that even extremely cold ice can be made to flow slowly; whence ice must have some true viscosity. Recently microthermometers are used for judging the approach of icebergs by the *rise* of the temperature a few fathoms below the surface.

Ice has always been esteemed as a luxury in warm weather; and this early led to the storing of it in winter and preserving it for summer use. Greeks and Romans at first preserved snow, closely packed in deep underground cellars. Nero established actual ice-houses in Rome, but snow was also brought to Rome from the summits of distant mountains. The trade in ice in Great Britain was till of late chiefly confined to the supply required by first-class fishmongers and confectioners—the private residences of the more opulent families being furnished with ice-houses (generally solid-built cellars, wholly or partially underground). But ice has come to be more and more largely used in preserving provisions, both in refrigerating-chambers and otherwise. It is also used by brewers. In surgical operations ice is used to produce partial anaesthesia; it serves in fevers to cool the mouth and reduce the internal temperature, while ice in bags, applied to the spine, is found helpful in many cases of sea-sickness, and in other applications. In America, in hot weather, ice is employed for preserving dead bodies between death and burial. Ice was imported into England from Norway in 1823; in 1805 it was exported from Boston to the West Indies, and later to India, China, and Batavia. About 1840 the Wenhams Lake Ice Company commenced sending ice from Boston to Britain, which now gets it mainly from Norway. In severe winters the Norfolk Broads supply a quantity.

The building of ice-edifices is a Russian winter amusement. Montreal set the example of an annual ice-carnival. The Canadian ice-boat or ice-yacht is not so much a boat as a triangular framework of wood, running by means of a sail—with the broad end foremost—on three skates or runners, 3 feet long by 8 inches deep. There is but one large sail, usually triangular, fastened to a boom and yard, which may be over 30 feet in length. Such an ice-boat may be steered by the rudder-skate in almost any direction not in the teeth of the wind, and may attain an average speed of thirty or forty miles an hour, and sometimes as much as sixty-five miles. Snow seriously reduces the speed. Ice-breakers are ships with sliding bows which override and crush down the ice by their weight. For means devised for artificial freezing, see FREEZING MIXTURES, and REFRIGERATION.

Ice Age. See GLACIAL PERIOD.

Iceberg. See ICE.

Iceland is an island in the north Atlantic immediately south of the Polar Circle, and lies between 63° 23' and 66° 33' N. lat., 13° 22' and 24° 15' W. long. The meridian of Ferro crosses the middle of the island. The distance to Greenland is about 250 miles, to Norway 600, to Scotland 500. The length E. to W. is 300 miles, the breadth N. to S. 200; the area 40,000 sq. m. The S. coast has no inlets; the others, especially the NW. and E. coasts, are very much indented by firths and bays. As a whole, Iceland may be said to be a tableland about 2000 feet high. In some parts it slopes pretty evenly down to the coast, as is the case on the south side between Eyafjallajökull and Reykjanes. Here is the largest extent of lowland, about 1400 sq. m. The next largest piece of lowland is the Borgarfjord, which extends to the Snaefellsjökull range of hills, and is about 400 sq. m. The firths in the north-west, in the north, and in the east may be looked upon as so many cuttings in the tableland effected by volcanic and glacial action during former geological periods of the island. In most cases these cuttings are comparatively narrow, and hills rise to about 2000 feet abruptly from the water, ending in steep precipices, which afford breeding-places to an immense number of sea-fowl. This is especially the case in the north-west and the east. In the north, and in some parts of the east, there are several broad valleys running from the firths into the interior. Iceland is throughout volcanic, and, according to geologists, it owes its existence entirely to volcanic action. The interior and highest part of the island consists of volcanic tufa; the hills of the east and west consist for the most part of basalt. The whole of the interior is occupied by barren sands, lava tracts, and icefields. The largest of these lava tracts is Odáthahraun, about 1200 sq. m. The largest icefield is that of Vatnajökull, about 3000 sq. m., and all the icefields together cover 5360 sq. m. The highest mountain is Hvannadalshnukur, 7066 feet above the sea, practically part of Óraefajökull, on the south edge of Vatnajökull. The upper parts of all mountains above 4000 feet are covered with everlasting snow or ice, as the snow-line is usually at from 3000 to 4000 feet. There are twenty volcanoes which have been active at one time or another since the island became inhabited. The most famous of these is Hekla (q.v.) or Hecla, because its eruptions have been most frequent. There are, however, other volcanoes, such as Laki, near Skaptá, which have been the seats of more gigantic eruptions. This volcano threw out in 1783 a lava-stream about 45 miles in length and nearly 15 miles in breadth. Such an outpour from one volcano at one time is unexampled anywhere else. The south-west peninsula, Reykjanes, has frequently been disturbed by volcanic outbursts, which have not been confined to the land, but islands in the sea round it have been thrown up or submerged alternately by submarine volcanic action. As a result of this volcanic activity, 2400 sq. m. of Iceland are covered with lava. Many of the ice-hills have been active volcanoes during the last 600 years, such as Óraefajökull and Eyafjallajökull. These ice-volcanoes never throw out any lava, but mud and ashes. The numerous hot springs scattered about the island are also connected with the volcanic fires; these are in many parts made use of by the inhabitants for cooking and washing purposes. There is great difference in the heat of these springs; some are just warm enough for bathing; others convert their water into steam at a degree far above the boiling-point. The most famous of these hot springs is Geyser. Earthquakes sometimes do a great deal of damage in

various parts of the island, as in 1896. See GEYSER.

Many considerable rivers run from the interior either north or south, but none of them are navigable, because of their rapidity. The longest are Þjórsá (Bull River) in the south, Jökulsá á Fjöllum and Skjálfandafjót in the north, each being above 100 miles in length. Of the numerous lakes, Thingvallavatn and Thorisvatn in the south and Mývatn in the north are the largest. Of the many pretty waterfalls may be mentioned Gullfoss in Hvítá, Gothafoss in Skjálfandafjót, and Dettifoss in Jökulsá.

Iceland is not rich in economic minerals, at least in paying quantities. There are many sulphur-mines, and some of them have been worked till lately with English capital, but not with profit. Surtarbrandur (lignite) and brown coal are found in many places, as well as iron and lime. Coal is worked.

The climate of the south of Iceland is somewhat like that of the north of Scotland—i.e. rather wet and changeable, but colder. In the north of the island the climate is drier and colder still. Thunderstorms are rather rare, and usually occur in winter. The winter is mild considering the latitude, but spring and summer are frequently cold. The mean temperature of Grimsey off the north coast is about 35° F.; that of the coldest mountain districts about 31° F. The greatest peculiarity of the Iceland climate is the varying mean temperature of the same month, the difference sometimes being 27°. This is owing to the arrival or non-arrival of the Greenland ice, which not infrequently blocks up the north and east coasts from April to September.

Turnips, carrots, cabbages, and potatoes thrive very well, and are now cultivated to some extent. The grasses, both wild and cultivated, however, are the principal product of the island. The melur (*Elymus arenarius*) or lyme-grass, closely related to barley, is used as a sand-binder. Birch copse, seldom exceeding 12 feet in height, is disappearing. There are some willows, rowans, and juniper-bushes. Amongst the heather are found crowberries and whortleberries.

The only wild mammals are the fox and the reindeer; there are both white and blue foxes. Reindeer were introduced in 1770, and there are still a few herds of them running wild on the hills in the interior; they are of very little use to the inhabitants. Of domestic animals the sheep is the most important; it is usually horned, sometimes even with three and four horns, and has some general resemblance to the blackfaced sheep of Scotland. The lambs are weaned about the end of June, and the ewes are milked. Large numbers of them are now exported alive to Scotland and England. The cows are of a small breed, but yield a larger quantity of milk in proportion to their size than most other cows. The ponies are generally about 12 hands, but very strong and sure-footed. Thousands are brought to Scotland every year. The genuine Iceland dog has some resemblance to the Eskimo dog and the Scotch collie. Of birds there are immense numbers, especially of water-fowl, the most important of which is the Eider-duck (q.v.); it yields large quantities of eider-down, and is almost a domesticated bird in many parts of the island. The ptarmigan is the only game-bird. The most remarkable bird of prey is the Icelandic falcon, formerly so much esteemed for falconry. Of other birds, the whooper or wild swan may be mentioned; it breeds largely in Iceland. The sea around the coasts is very rich in fish, especially cod and herring; the cod-fisheries have been carried on a long time by the islanders, and now also by the French and others. Little attention was paid to the her-

ring-fishing till about 1880, when it was largely developed by the Norwegians, as it is now also by the Icelanders themselves. Fin-backed whales, of late successfully fished by the Norwegians, and seals are also numerous. Many of the salmon and trout rivers are now rented by Englishmen. 'There are no snakes to be met with throughout the whole island'—to cite the whole of the memorable seventy-second chapter repeated by Dr Johnson from Horrebrow's *Natural History of Iceland* (Copenhagen, 1750; Eng. trans. 1758).

Iceland was discovered about the beginning of the 9th century by Irishmen or Scots, but they did not make any permanent settlement. About seventy years later it was rediscovered and colonised by Norwegians, who preferred to leave their native land rather than submit to the rule of Harold Haarfager. Many of them had previously settled in the Orkneys, Hebrides, and Ireland; and when they were not safe there from the attacks of Harold, they went to Iceland, and a considerable number of Irishmen and Scotsmen went with them. Ingolf was the first settler. In about sixty years the whole island was inhabited, and an aristocratic republic was formed, the central point of which was the Althing which met every year at Thingvellir. In 1262-64 the Icelanders acknowledged the sovereignty of the king of Norway; and in 1388, when Norway was united with Denmark, Iceland shared the same fate. When, however, Denmark had to give up Norway in 1814, Iceland remained with Denmark, because, it is said, the negotiators of the peace of Vienna in 1814 did not know that there was such an island as Iceland in existence. The Althing continued under the Norwegian and Danish rule with very limited powers till 1800, when it was abolished. In 1874 the king of Denmark gave the island a new constitution (modified in 1903 and 1915), according to which the Althing, which had been reorganised in 1843, obtained legislative powers in all matters concerning Iceland. The dissatisfaction of the Icelanders was not removed by concessions, and the movement for separation grew until, in 1918, Denmark fully recognised Iceland as a sovereign state, united only by the personal bond of a common king. For the present foreign affairs are left to the Danish foreign office (with Icelandic advice), though no treaty is binding on Iceland without its own sanction, and Danes in Iceland and Icelanders in Denmark have equal privileges with natives. A joint committee advises on co-operation in legislation. Iceland has no army or navy, and is permanently neutralised. The Althing consists of 42 members, elected by universal suffrage, 36 by constituencies, 6 by proportional representation by the whole country. Women have had votes since 1915, and are eligible for all offices. The 36 members elect 8 of their own number to sit with the 6 as an upper house. The remaining 28 form a lower house. There is a Supreme Court (1920) at Reykjavik. In the year 1000 Christianity was introduced in Iceland, and a century later two bishops' sees, one at Skálholt, the other at Hólar, were established. About the middle of the 16th century the Reformation was introduced, and since then the Icelanders have remained Lutherans. Church matters are now superintended by one bishop at Reykjavik.

The most notable events in the history of Iceland from its union with Norway are a long series of afflictions and calamities, caused by volcanic outbursts, severe seasons, epidemics (such as the black death in 1402, the great plague in 1494, the ravages of smallpox), and in some cases by misgovernment. The population of Iceland in 1801 was 46,240; in 1880, 72,422; in 1890, 70,927; in 1920, 94,690, though many thousands have emigrated to America. In the 12th and 13th

centuries Iceland produced more vernacular literature than any other nation in Europe, and from that time love of information has been a distinguishing feature of the Icelanders. At the present day elementary education is so general that a child of ten unable to read is quite an exception, and most of them can write also. There are several schools for children, but for the most part education is imparted at home. There are several higher schools and colleges; and Reykjavík has a university. Many farmers are acquainted with two foreign languages. Reykjavík, on the south-west coast, is the capital of Iceland, with about 20,000 inhabitants. Isafjörður in the north-west and Akureyri in the north, Hafnarfjörður and Vestmannaeyjar in the south, have each some 2000 inhabitants. For the rest the population is mostly scattered all round the island on isolated farms. The principal means of support of the Icelanders are the rearing of live-stock and fishing. The chief exports are: live sheep, salt mutton, wool, sheep-skins, tallow, horses, salted cod, haddock, ling, salted salmon, cod-liver oil, shark-liver oil, eider down and feathers. The imports are: corn and breadstuffs, coffee, chicory, sugar, salt, tobacco, petroleum, coal, fishing lines and ropes. Besides these, timber, iron, cotton goods, and other clothing stuffs are imported. Trade with Iceland was confined for several centuries to Copenhagen, which has the largest part of it still. Since the year 1854 trade has been free to all nations, and now it is going more and more to Leith and Newcastle. The only native industry consists in working the wool of the sheep into various articles of clothing; this is chiefly done by the women in winter. The Icelanders make a sort of tweed which they call *vathmál*, and this is the principal clothing material of the inhabitants. On most farms there is an old-fashioned loom in which the *vathmál* is woven; but there are some factories. There are no railways, but over 320 miles of carriage roads outside the towns.

ICELANDIC LANGUAGE AND LITERATURE.—The language which is now called *Icelandic* was down to the 13th century spoken all over Scandinavia—i.e. in Norway, Sweden, and Denmark, as well as in the Faeroe Islands, Shetland, Orkney, the Hebrides, and on the coasts of England, Scotland, and Ireland. Formerly its name was *Dönsk tunga* (the Danish tongue) or *Norraena* (the Northern tongue). Its similarity to Old English was so close that the ancient Icelandic authors asserted that the same language was spoken in England till the arrival of William the Conqueror as in Scandinavia. This is the language which the Norwegians brought over to Iceland in the 9th century, and because it is now nowhere spoken but in Iceland it is called *Icelandic*. The present Danish and Swedish stand in the same relation to it as Italian and Spanish stand to Latin. In Iceland it has undergone so little change that any Icelandic child who has learned to read can read the sagas and songs of the 12th and 13th centuries as easily as an English child can read Shakespeare. There is, however, reason to believe that the pronunciation has been somewhat altered, especially that of the vowels and two of the consonants: the *k* and the *t* have in some words been

softened into *g* and *ð* (th) respectively. The vocabulary, the inflexions, and the grammatical construction have been preserved almost unaltered. The relationship to Old or Modern English may be seen at a glance, so many words in both languages being the same. We will take as instances several names of parts of the body, as Icelandic *hönd*, 'hand'; *finger*, 'finger'; *fótr*, 'foot'; *bak*, 'back.' And if this is the case with English, it is still more so with Scots, for generally, where Scots differs from ordinary English in pronunciation of a word, it is identical with that of Icelandic. In some cases the consonant has been softened in English where it has remained hard in Icelandic; thus the letters *sh* represent a softened form of *sk*—e.g. 'shall' is in Icelandic *skal*, 'shell' is *skel*, 'ship' is *skip*, and instances of this kind might be multiplied infinitely. Icelandic is an inflectional language, having four cases not only for the nouns but also for each gender of the adjectives, some of the numerals, and the pronouns. With regard to the phonetics of the language, it may be remarked that vowel change (*umlaut*) has been carried further than in any other of the Teutonic tongues. The chief characteristics which distinguish Icelandic from German and English are the ending of the infinitive in a vowel, usually *a*, the suffixing of the definite article, and the passive or middle voice of the verb. To every student of Northern history the question must occur, why this ancient tongue has been preserved in Iceland, and not as well in some other parts of the north which have been quite as isolated as Iceland. We have no hesitation in giving as reason the fact that the Icelanders were the only people who had any literature in it, and always took great interest in that literature. This literature has not merely a philological interest, but even more historical interest, as it contains a full account of the men who left their mark in every corner of Europe, who were, in fact, masters of Europe during the 9th and 10th centuries, and whose language and laws are at this moment important elements of the language and institutions of the English-speaking race. It also throws no obscure light on the beliefs and modes of life of our common ancestors.

The earliest monuments of this tongue are found in the Runic inscriptions of Scandinavia (see **RUNES**). The remains thus found are indeed very different from the language as it appears in Icelandic literature; there is, however, sufficient similarity to show that the language there employed is really the same. The Runic monuments range from the 8th to the 12th century. The earliest literary productions in the Icelandic tongue are the mythical songs contained in the so-called poetical Edda (q.v.), the collection of which has, we believe erroneously, been attributed to Sæmund the Learned, who died in 1133. It is impossible to ascertain how far these songs were brought to Iceland by the Norwegians, though some of them seem to point to a time anterior to the settlement of the island. The only thing we know for certain is, that they existed in Iceland in the later part of the 12th century. The identification of some or all of them with either Norway or the Western Islands is founded on no firmer basis than mere conjecture. These songs may be divided into mythical and heroic songs. The mythical songs contain an account of the gods and giants, the creation of the world and of man, the world-long struggle of the gods with the giants or Titans of the Northern mythology, the day of judgment, or the destruction of the gods, the giants, and the world, out of the ruins of which a new heaven and a new earth are to arise. One of the songs of this collection is the *Hávamál* (the Song of the High One—viz. Odin); it is a didactic

various parts of the island, as in 1896. See GEYSER.

Many considerable rivers run from the interior either north or south, but none of them are navigable, because of their rapidity. The longest are Thjórsá (Bull River) in the south, Jökulsá á Fjöllum and Skjálfandafjót in the north, each being above 100 miles in length. Of the numerous lakes, Thingvallavatn and Thorisvatn in the south and Mývatn in the north are the largest. Of the many pretty waterfalls may be mentioned Gullfoss in Hvítá, Gothafoss in Skjálfandafjót, and Dettifoss in Jökulsá.

Iceland is not rich in economic minerals, at least in paying quantities. There are many sulphur-mines, and some of them have been worked till lately with English capital, but not with profit. Surtarbrandur (lignite) and brown coal are found in many places, as well as iron and lime. Coal is worked.

The climate of the south of Iceland is somewhat like that of the north of Scotland—i.e. rather wet and changeable, but colder. In the north of the island the climate is drier and colder still. Thunderstorms are rather rare, and usually occur in winter. The winter is mild considering the latitude, but spring and summer are frequently cold. The mean temperature of Grimsey off the north coast is about 35° F.; that of the coldest mountain districts about 31° F. The greatest peculiarity of the Iceland climate is the varying mean temperature of the same month, the difference sometimes being 27°. This is owing to the arrival or non-arrival of the Greenland ice, which not infrequently blocks up the north and east coasts from April to September.

Turnips, carrots, cabbages, and potatoes thrive very well, and are now cultivated to some extent. The grasses, both wild and cultivated, however, are the principal product of the island. The melur (*Elymus arenarius*) or lyme-grass, closely related to barley, is used as a sand-binder. Birch copse, seldom exceeding 12 feet in height, is disappearing. There are some willows, rowans, and juniper-bushes. Amongst the heather are found crowberries and whortleberries.

The only wild mammals are the fox and the reindeer; there are both white and blue foxes. Reindeer were introduced in 1770, and there are still a few herds of them running wild on the hills in the interior; they are of very little use to the inhabitants. Of domestic animals the sheep is the most important; it is usually horned, sometimes even with three and four horns, and has some general resemblance to the blackfaced sheep of Scotland. ICELANDIC LANGUAGE AND LITERATURE.—The language which is now called *Icelandic* was down to the 13th century spoken all over Scandinavia—i.e. in Norway, Sweden, and Denmark, as well as in the Faeroe Islands, Shetland, Orkney, the Hebrides, and on the coasts of England, Scotland, and Ireland. Formerly its name was *Dönsk tunga* (the Danish tongue) or *Norraena* (the Northern tongue). Its similarity to Old English was so close that the ancient Icelandic authors asserted that the same language was spoken in England till the arrival of William the Conqueror as in Scandinavia. This is the language which the Norwegians brought over to Iceland in the 9th century, and because it is now nowhere spoken but in Iceland it is called *Icelandic*. The present Danish and Swedish stand in the same relation to it as Italian and Spanish stand to Latin. In Iceland it has undergone so little change that any Icelandic child who has learned to read can read the sagas and songs of the 12th and 13th centuries as easily as an English child can read Shakespeare. There is, however, reason to believe that the pronunciation has been somewhat altered, especially that of the vowels and two of the consonants: the *k* and the *t* have in some words been

softened into *g* and *ð* (th) respectively. The vocabulary, the inflexions, and the grammatical construction have been preserved almost unaltered. The relationship to Old or Modern English may be seen at a glance, so many words in both languages being the same. We will take as instances several names of parts of the body, as Icelandic *hond*, 'hand'; *finger*, 'finger'; *fótr*, 'foot'; *bak*, 'back.' And if this is the case with English, it is still more so with Scots, for generally, where Scots differs from ordinary English in pronunciation of a word, it is identical with that of Icelandic. In some cases the consonant has been softened in English where it has remained hard in Icelandic; thus the letters *sh* represent a softened form of *sk*—e.g. 'shall' is in Icelandic *skal*, 'shell' is *skel*, 'ship' is *skip*, and instances of this kind might be multiplied infinitely. Icelandic is an inflectional language, having four cases not only for the nouns but also for each gender of the adjectives, some of the numerals, and the pronouns. With regard to the phonetics of the language, it may be remarked that vowel change (*umlaut*) has been carried further than in any other of the Teutonic tongues. The chief characteristics which distinguish Icelandic from German and English are the ending of the infinitive in a vowel, usually *a*, the suffixing of the definite article, and the passive or middle voice of the verb. To every student of Northern history the question must occur, why this ancient tongue has been preserved in Iceland, and not as well in some other parts of the north which have been quite as isolated as Iceland. We have no hesitation in giving as reason the fact that the Icelanders were the only people who had any literature in it, and always took great interest in that literature. This literature has not merely a philological interest, but even more historical interest, as it contains a full account of the men who left their mark in every corner of Europe, who were, in fact, masters of Europe during the 9th and 10th centuries, and whose language and laws are at this moment important elements of the language and institutions of the English-speaking race. It also throws no obscure light on the beliefs and modes of life of our common ancestors.

The earliest monuments of this tongue are found in the Runic inscriptions of Scandinavia (see RUNES). The remains thus found are indeed very different from the language as it appears in Icelandic literature; there is, however, sufficient similarity to show that the language there employed is really the same. The Runic monuments range from the 8th to the 12th century. The earliest literary productions in the Icelandic tongue are the mythical songs contained in the so-called poetical Edda (q.v.), the collection of which has, we believe erroneously, been attributed to Sæmund the Learned, who died in 1133. It is impossible to ascertain how far these songs were brought to Iceland by the Norwegians, though some of them seem to point to a time anterior to the settlement of the island. The only thing we know for certain is, that they existed in Iceland in the later part of the 12th century. The identification of some or all of them with either Norway or the Western Islands is founded on no firmer basis than mere conjecture. These songs may be divided into mythical and heroic songs. The mythical songs contain an account of the gods and giants, the creation of the world and of man, the world-long struggle of the gods with the giants or Titans of the Northern mythology, the day of judgment, or the destruction of the gods, the giants, and the world, out of the ruins of which a new heaven and a new earth are to arise. One of the songs of this collection is the *Hávamál* (the Song of the High One—viz. Odin); it is a didactic

poem containing rules of conduct in various situations and views of life. The heroic songs mostly treat of the same subject as the German *Nibelungenlied*. Some of these songs contain the most exquisite expressions of Icelandic poetry. There are several other songs of the same type as the Edda. All these songs are alliterative; their characteristics are simplicity of diction and natural expression. By the side of these popular songs a more artificial poetry was developed by the Skalds (q.v.); here rhyme was added to alliteration, and the expression was so artificial that they could be understood by the initiated only. As the theme of their poems was usually a king or chief, whose heroic deeds they celebrated in their songs, this kind of poetry has been called court-poetry. Many of these songs formed the nucleus of the later saga. Either the Skald himself, or another person who had learned his poem, would recite it, give explanations of it, and add further particulars to the life of him whom the poet celebrated, and thus the saga took shape shortly after the celebration of the events in the song. Thus a literature arose without the use of letters.

The runes were used only for inscriptions, not for literary purposes. Some authorities, however, are of opinion that the earliest Icelandic writings were in runes, but, as there is not a single tittle of such writing left as evidence, the conjecture seems very hazardous. The first Icelandic bishop, Isleif, who died in 1080, introduced the Latin alphabet, and taught young men in preparation for the priestly office. In the beginning of the 12th century another bishop had a school where Latin was taught. Shortly afterwards began that literary activity which made the Icelanders famous. The old prose literature of Iceland consists for the most part of sagas—i.e. tales, both historical and fabulous. They are all more or less in the form of biographies; their authors are for the most part unknown. With regard to the scenes of the sagas, they may be divided into Icelandic sagas, or biographies of Icelanders in Iceland, the sagas of the kings of Norway, and sagas concerning other countries. These sagas give a faithful picture of the life and manners of those times, but chronology is usually their weakest point. The father of Icelandic literature was Ari the Learned (1067–1148). He was the first who began to write down the sagas, most of which had already been formed in the mouth of the saga-teller. The principal works of Ari are the *Landnámabók*, or account of the settlement of Iceland, containing the names, genealogy, and brief accounts of every settler. It is an evidence of very careful research and wonderful memory of the author. No other country in the world has such an account of its earliest history. He also wrote a small book called *Libellus Islandorum*, on the history of Iceland down to 1135, and an account of the introduction of Christianity called *Kristni Saga*. All these have come down to us; but he also wrote a larger book on Iceland which is lost, and the lives of the earliest kings of Norway, which are also lost except so far as they may be embodied by Snorri Sturluson (1178–1241), the historian and poet. His best-known works are the prose Edda, or manual of Scandinavian mythology and Icelandic poetry, and the *Lives of the Kings of Norway*, or *Heimskringla*, down to the death of Sigurd the Crusader (1130). The third name is that of Sturluson's nephew, Sturla Thordarson (1214–84), also a poet and historian. He wrote the *Íslendinga Saga*, also called *Sturlunga*, a graphic account of the feuds between the chiefs of Iceland in the 13th century, which resulted in the subjection of the island to the king of Norway. He also wrote the life of Hákon the Old, who died at Kirkwall in 1263, and that of his son Magnus.

Besides the sagas and poetry there are also found grammatical essays from the 12th and 13th centuries, astronomical treatises, a guide for travellers to Rome and Jerusalem. A remarkable work appeared in the 13th century called *Konungs Skuggsjá* ('king's mirror'), which contains a philosophical contemplation of life, with rules for conduct under various circumstances and in the company of all sorts of people. The old Icelanders were no less industrious translators than original writers, for they seem to have translated any foreign book that came into their hands. Thus they translated many medieval romances, such as the legends of King Arthur, and these translations are now of great value for the textual criticism of the originals. Among the most remarkable translations of those times is a version of the Old Testament, intermingled with various observations on natural history, compiled from medieval sources. This is perhaps the oldest translation of the Bible in any living language. There are also translations of a great number of homilies, of lives of saints, and legends of the church. The code of laws of the Icelandic republic, called *Grágás* (gray goose), first written down in 1118, affords ample evidence of great skill in legislative enactments, and is well worth studying in connection with the legal history of other Teutonic nations.

Shortly after 1800 the literary productiveness of the Icelanders ceased, except for the writing of annals, which had begun in the preceding century. The principal literary activity of the 14th century consisted in copying and making collections of the labours of former centuries. Many of the sagas have been preserved in these copies only, the originals being lost. The 15th century is almost a blank as far as literary activity is concerned, if we except a few song-writers; yet even then there were some students of the old sagas. About the middle of the 16th century a new turn was given to the literary pursuits of the Icelanders by the introduction of the Reformation. The whole Bible was translated and published in 1584, and many other theological works from Danish and German. In the 17th century the interest in the old literature was reawakened, and many parchments were transcribed. At this time also the collecting of manuscripts began, and they were carried partly to Sweden and partly to Denmark. To the latter country they were taken by the indefatigable collector Arni Magnússon, who died in 1730, after having bequeathed his collections to the university of Copenhagen. There is no doubt that this exportation of the manuscripts was very fortunate for their preservation. From this time the literary treasures of Iceland began to be known abroad; the first to make known the historical value of the sagas was the Icelanders Torfæus, who died in 1719. Since then there has been no want of diligent and careful students of Icelandic literature both among Icelanders, Scandinavians, Germans, and lately also among the English.

The literary activity of the modern Icelanders is not confined to the study of the old literature alone; there is also a considerable modern literature, though it is comparatively less interesting. Iceland has always been and still is rich in song-writers, especially of a lyrical and religious tendency. To the natural history and the history of the island itself there have been valuable contributions. Considering the population and other circumstances of the island, it cannot be denied that the Icelanders at the present day compare favourably in respect to literary activity with any other people in similar circumstances.

The best guide to the old literature of Iceland is to be found in the *Prolegomena* to the *Sturlunga Saga*, edited by Dr G. Vigfússon (Oxford, 1878). See also the *Corpus*

Poeticum Boreale: the poetry of the Old Northern tongue to the 13th century (2 vols. 1883), edited, translated, and illustrated by Vigfússon and Powell, and their *Origines Islandicæ* (1905); also the *Saga Library*, edited by Morris and Magnusson (6 vols. 1891-1906), and W. A. Craigie, *The Icelandic Sagas* (1913).

Iceland Moss (*Cetraria islandica*), a lichen found in all the northern parts of the world, and valuable on account of its nutritious and medicinal properties. It is collected as an article of commerce in Norway and Iceland. In very northern regions it grows even near the level of the sea; in more southern countries it is found on mountains. It is not uncommon in the mountainous parts of Britain, although not turned to any economic account. In Carniola it is used for fattening cattle and pigs. It grows in extreme abundance in Iceland on tracts otherwise desert; and numerous parties migrate from great distances with horses, tents, and provisions, in the summer months, for the sole purpose of gathering it as an article of commerce and for food. In many places this lichen thickly covers the whole surface of the ground, growing about 1½-4 inches high, and consists of an almost erect Thallus (q.v.). It is of a leathery and somewhat cartilaginous substance. When Iceland moss is used as an article of food its bitterness is first partially removed by steeping in water, after which, in Iceland and other northern countries, it is sometimes pounded and made into bread; or it is prepared by boiling, the first water being rejected. It is often boiled with milk, making a kind of jelly, either with milk or water. It is an agreeable article of food, and

Iceland Moss (*Cetraria islandica*).

very suitable for invalids. It contains about 80 per cent. of a kind of starch called *Lichen Starch*, or *Lichenin*, and owes its bitterness to an acid principle, *Cetraria Acid*.—An allied species, *Cetraria nivalis*, growing in northern countries, possesses similar properties.

Iceland Spar, transparent calc-spar, or calcite, CaCO_3 ; it may be split along its cleavage-planes into an obtuse rhombohedron, and is doubly refracting. See CALCITE.

Iceni. See BOADICEA.

Ice Plant (*Mesembrianthemum crystallinum*), an annual herbaceous plant, a native of Africa and of the south of Europe, remarkable for the watery vesicles (*papulae*) with which its whole surface is covered, and which have the appearance of granules of ice, and sparkle in the same manner in the sun. It is common as a tender annual in our greenhouses, and grows in the open garden during summer; the leaves are used for garnishing dishes. The expressed juice of the plant has been greatly extolled as a remedy for diseases of the mucous membrane of the lungs and urinary passages, and also for dropsy. The seeds are used for food in the Madeira Islands. The ashes supply barilla, and the plant is burned on this account in countries where it abounds. The plant is valuable for extracting soda, potash, and other alkaline salts from unproductive soils, rendering them fit for culture. It is also used in the south of France. See MIMICRY.

Ice-sheet. See GLACIAL PERIOD, GLACIERS.

Ice-stone. See CRYOLITE.

Ice-yachting. See ICE.

Ichang, a walled town in the Chinese province of Hu-peï, stands on the Yang-tze-kiang, where it escapes from the limestone gorges and ravines of its middle course, and 1000 miles from Shanghai at its mouth. In 1877 it was declared open to foreign trade, but in consequence of the difficulties connected with the navigation of the river, the competition of the Chinese, and the jealousy of the Chinese officials it advanced but slowly. Nevertheless trade increased greatly, and is still considerable. The imports are cottons and kerosene, and the exports hides, oil, varnish, and tallow. Ichang is connected with Hankow by telegraph, and so with the outer world. Pop. 70,000.

Ich Dien ('I serve'), the motto of Edward the Black Prince, whose badge was a single ostrich feather, afterwards three ostrich feathers. The story that he adopted both motto and badge from John, the blind king of Bohemia, after the battle of Crécy, is not borne out by historical investigation. Since Edward's time the motto 'Ich Dien' and the badge of three ostrich feathers have been employed as the cognisance of the Princes of Wales. The motto may refer to *Galatians* iv. i. Its dialect seems to have been originally Low Franconian ('Ich dene'). See *Dict. Nat. Biog.*, vol. xvii. p. 92; *Times*, Lit. Supp., 1st August 1918.

Ichneumon (*Herpestes*), a genus of digitigrade carnivorous quadrupeds of the family Viverridae, having a much elongated body, small head, sharp muzzle, rounded ears, and short legs. The species, which are pretty numerous, are natives of Africa and the warmer parts of Asia. One, the Andalusian Ichneumon (*H. ichneumon*, var. *Wid-dringtonii*), occurs in the south of Spain. They feed on small quadrupeds, reptiles, eggs, and insects.

Egyptian Ichneumon (*Herpestes ichneumon*).

Some of them, particularly the Egyptian Ichneumon (*H. ichneumon*) and the Mangouste, Mongoose, or Mongoose (*H. griseus*) of India, have been greatly celebrated as destroyers of serpents and other noxious reptiles, many wonderful fables being super-added to the truth on this subject. The Egyptian Ichneumon, the ichneumon of the ancients, is larger than a cat, gray, with black paws and muzzle. It was a sacred animal among the ancient Egyptians. The ichneumon is easily domesticated, and is useful in keeping houses free of rats and other vermin. It is therefore not unfrequently domesticated in Egypt, as the mongoose also is in India. This species is rather smaller, of a lighter colour, and has a pointed tail. Introduced into Jamaica, the mongoose did admirable service in clearing the sugar-cane fields of rats; but became a plague by destroying poultry and harmless animals.

Ichneumon, a name applied to the members of a very large family of insects (Ichneumonidae), included in the order Hymenoptera, and notable because the larvæ are parasitic in, or sometimes on,

other insects. There are several thousand species, represented in all parts of the world, including many minute forms and also some of the largest insects. The long antennæ have many joints; the abdomen is usually joined to the thorax by a narrow waist; the females are provided with ovipositors, which are in some cases very prominent. With these they lay their eggs in the ova, larvæ, or adults of other insects, and sometimes also of spiders. The ichneumon embryos develop in the safe and comfortable hiding-place thus afforded, and utilise their hosts as food for a while, but sooner or later, before or oftener after pupation, leave them dead or dying. Sometimes, curiously enough, the ichneumons themselves fall victims to a similar trick played upon them by members of the same or nearly related families. As adults, these insects feed on the juices of flowers. The parasitic habit of the larvæ is sometimes of economic importance, since they thus destroy injurious insects. Thus, *Microgaster glomeratus* and *Pimpla instigator* are parasitic on the caterpillars of the cabbage butterfly, and *Aphidius* upon aphides.

Ichology (Gr., 'science of footprints'). See FOSSILS.

Ichor, the ethereal fluid that supplied the place of blood in the veins of the gods of Greek mythology. The name is applied in medicine to the thin watery discharge from a wound.

Ichthyodorulite (Gr., 'fish-spear-stone'), the name given to fossil fish spines, not uncommon in the stratified rocks.

Ichthyology (Gr. *ichthys*, 'a fish,' *logos*, 'a discourse'), that branch of natural history which treats of Fishes (q.v.).

Ichthyornis. See ODONTORNITHES.

Ichthyosaurus (Gr., 'fish-reptile'), a remarkable genus of reptiles which inhabited the sea during the deposition of the Mesozoic strata. Like the modern Cetacea, their structure was modified to suit their aquatic life. The body was shaped like that of a fish, the limbs were developed into paddles, and the tail, long and lizard-like, was furnished, it is believed, with a fleshy fin, as in the dolphin, except that its position was vertical. The head was large, and produced into a long and pointed snout, resembling that of the crocodile, except that the orbit was much larger, and had the nostril placed close to it, as in the whale, and not near the end of the snout. The jaws were furnished with a large series of powerful conical teeth, lodged close together in a continuous groove, in which the divisions for sockets, which exist in the crocodile, were indicated by the vertical ridges on the maxillary bone. The teeth were hollow at the root, sheathing the young teeth, which gradually absorbed the base of the older ones, and, as they grew, pressed them forward, until they finally displaced them. The long and slender jaws were strengthened to resist any sudden shock by being formed of many thin bony plates, which produced light and elastic as well as strong jaws. The most remarkable feature in the head was the eye, which was not only very large—in some specimens measuring 13 inches in

diameter—but was specially fitted to accommodate itself for vision in air or water, as well as for speedily altering the focal distance while pursuing its prey. The structure, which thus fitted the eye so remarkably to the wants of the animal, consists of a circle of thirteen or more overlapping sclerotic bony plates surrounding the pupil, as in birds. This circle acted as a sort of self-adjusting telescope, and, assisted by the extraordinary amount of light admitted by the large pupil, enabled the ichthyosaurus to discover its prey at great or little distances in the obscurity of the night, and in the depths of the sea. The neck was so short that the body was probably not in the least constricted behind the head. The backbone was fish-like; each joint had both its surfaces hollow, making the whole column very flexible. The small size of the paddles compared with the body, and the stiffness of the short neck, seem to suggest that the tail must have been an important organ of motion. Professor Owen was satisfied that it was furnished with a vertical tail, because the vertebrae are compressed vertically, and also because the tail is frequently found disarticulated a short distance from its extremity, as if the weight of the upright tail had caused it to fall when the animal had begun to decompose. The hindmost caudal vertebrae extend into the lower lobe of the tail. The anatomy of the ichthyosauri suggests that they must have been active in their movements, and consequently, with their predaceous habits, dangerous enemies to the smaller animals of the

Mesozoic seas. That their principal food consisted of fishes is evident from the masses of broken bones and scales of contemporary fishes that have been found under their ribs in the place where the stomach of the animal was situated. Not infrequently entire skeletons of small individuals have been found within the thoracic and abdominal cavity of larger ones. As these small skeletons are complete and uninjured and of the same species as that in which they occur, Professor Seeley thought that some of the ichthyosauri were viviparous.

The remains of ichthyosauri are peculiar to the Mesozoic strata, occurring in the various members of the series from the Lower Lias to the Chalk, but having their greatest development in the Lias and Oolite. More than thirty species have been discovered; they differ from each other chiefly in the form of the head, some having a long and slender snout, like the gaviol of the Ganges, while others had short and broad heads, more like the common crocodile. The great repository for ichthyosaurian remains hitherto has been the Lias at Lyme Regis.

Ichthyosis, or FISH-SKIN DISEASE, is characterised by a hardened, thickened, rough, and almost horny state of the cuticle in severe cases. Instead of exfoliating in fine, almost invisible flakes, it accumulates in irregular scale-like pieces, which may be removed, but are speedily reproduced. Perspiration is always absent or very deficient in the affected areas. The disease may affect almost the whole surface, or may be confined to a single part; and is most frequently, but not

always, congenital. It is attended by no constitutional disturbance, and the general health is often very good. The disease is, however, extremely obstinate, and when congenital may be considered as incurable. Treatment consists in the frequent use of warm or vapour or alkaline baths, so as to soften the thickened epidermis and to facilitate its removal, and friction by means of a piece of flannel or pumice-stone may be conjoined with the bath. The application of sulphur or resorcin to the skin has also the effect of promoting desquamation, and it is very important that after the bath some oil or fat should be rubbed into the skin. The internal administration of thyroid extract, cod-liver oil, &c., sometimes gives relief.

Icknield Street, a pre-Roman road of Britain, which ran along the crest of the Berkshire Downs and of the Chilterns. The name has been applied to other ancient roads. See a monograph by E. Thomas (1913).

Icolmkill. See IONA.

Iconium, an ancient town of Phrygia, on the western edge of the plateau that skirts the northern slopes of the Taurus Mountains, 310 miles E. of Smyrna. It was three times visited by St Paul, who founded there a Christian church. In 708 it fell into the hands of the Arab conquerors. Its prosperity culminated in the end of the 11th century, when it was made the capital of the Seljuk empire. In 1190 Frederick Barbarossa defeated the Turks in the neighbourhood, and captured Iconium. Some fifty years later its sultans were made the political playthings of the Mongols; and in 1392 they submitted to the suzerainty of the Ottoman Turks, though the state was not incorporated in the Ottoman empire until 1486. Being the meeting-point of some of the principal highways of Asia Minor, and a place of considerable trade, it failed not to figure prominently in the wars of the Turks. In 1832 Ibrahim Pasha defeated the Turks there.—The modern town, called KÖNIEH or KÖNİYA, the capital of the Turkish vilayet of Konieh, is a place of 70,000 inhabitants, who live by commerce, by making stockings and gloves, and on the contributions of the numerous pilgrims who visit the sacred tombs and other holy places of the town. Here is the principal monastery of the Mevlevi or 'dancing' dervishes in Turkey. Numerous ruins of mosques, madrasas (colleges), &c., attest the decayed splendour of the place.

Iconoclasts (Gr. *eikōn*, 'an image,' and *klaō*, 'I break'), the name used to designate those in the church, from the 8th century downwards, who have been opposed to the use of sacred images (i.e. of mosaics, pictures, and other sensible representations of sacred objects), or at least to the paying of religious honour or reverence to such representations. The iconoclast movement had its commencement in the Eastern Church. Opinion is divided as to the origin and antiquity of the practice of Image-worship (q.v.) in the church; but it is certain that in the 6th or 7th century it prevailed extensively, especially in the Eastern Empire, and that practices existed in some churches which were a source of much suspicion, and even of positive offence. Many bishops interposed to correct these abuses; but the iconoclast movement, strictly so called, began with the imperial edict issued in 726 by the Emperor Leo III., surnamed the Isaurian, forbidding the honours paid to sacred images, and even commanding the removal from the churches of all images, that of Christ alone excepted. This was followed by another decree in 730, which prohibited, under pain of death, as sinful and idolatrous, all acts of reverence, public or private, to images, and directed that wherever such images

should be found they should forthwith be removed or destroyed. The attempt to enforce this decree aroused great opposition, especially in the Greek islands and in Italy. The popes Gregory II. and Gregory III. protested vehemently against it, repudiated the imputation of idolatry, and explained the nature of the honours to images for which they contended. Leo persevered, nevertheless, in his opposition, which was continued by his successor, Constantine, surnamed Copronymus. Under this emperor a council was held in Constantinople in 754, in which the iconoclast decrees were affirmed in their fullest extent; and Constantine's son, Leo IV., renewed, on his accession in 775, the enactments of his predecessors. Under the widow of Leo, the Empress Irene, a council was held at Nicæa (787), in which these proceedings were condemned and revoked; but other succeeding emperors, Nicephorus (802-811), Leo V., the Armenian (813-820), Michael II., the Stammerer (820-829), and Theophilus (829-842), returned, with greater or less severity, to the policy of the iconoclast emperors. As regards the Greek Church the controversy may be said to have been finally settled under the Empress Theodora in a council held at Constantinople in 840, or at least by a subsequent one of 870. The modern usage of the Greek Church permits pictures, but rejects graven or sculptured representations of sacred objects. Except in Italy, the iconoclast controversy created but little sensation in the Western Church until the movement in the time of Charlemagne and his successors, noticed under the head IMAGE-WORSHIP.

Ictinus. Of Ictinus, who shares with Callicrates the glory of having designed the one perfect building which the world has ever seen, very little can be stated with certainty. In addition to his masterpiece, the Parthenon, the temple of Apollo Epicurus at Bassæ, near Phigalia, the sculptured reliefs from which are now in the British Museum, may be ascribed to him. He is also known to have been the architect of a temple at Eleusis, and to have written an exhaustive treatise upon the Parthenon, with which his name is indissolubly connected. See ATHENS.

Ida, a mountain-range in Asia Minor, extending from Phrygia through Mysia into the Troad. The city of Troy was situated at its base. It is the scene of many ancient Greek legends. The southern part of the range was called Gargarus, the highest peak of which is 5749 feet above the sea. Here there was a temple of Cybele, who therefore was called the *Idæan Mother*. From Ida flow several famous streams, as the Granicus, Simois, and Scamander.—There is another Ida (8055 feet) in Crete, extending from west to east, now called Psiloriti. Here Zeus was said to have been educated.

Idaho (*ī-da-ho*; Indian, 'gem of the mountains'), since 1890 one of the United States of America (till then a territory), is situated between 42° and 49° N. lat., and between 111° and 117° 6' W. long. In shape it is an irregular trapezoid. Its maximum length is about 480 statute miles; its breadth varies from about 44 miles at the 'pan-handle' which forms the northern part, to over 300 miles along the southern boundary. Its area is about 84,900 sq. m.

One of the main ranges of the Rocky Mountains, in various parts called the Cabinet, Cœur d'Alene, and Bitter Root mountains, forms the north-eastern boundary, separating Idaho from Montana. In the southern part this range is a portion of the continental divide between the Atlantic and Pacific oceans. About 70,000 sq. m. of the state is situated in the drainage basin of the Columbia River;

the remaining part lies in the Great Basin, its surface waters flowing into Great Salt Lake.

A comparatively small area in the south excepted, the entire surface is rugged and mountainous. In addition to the high range on the north-eastern border spurs of this range traverse the state in a direction generally east and west. Of these the Salmon River Mountains are perhaps the most noteworthy, as they separate what is popularly known as Northern Idaho from the plateau-region in the central and southern part. All these ranges are high, their summits reaching elevations of 10,000 feet and upwards. The average altitude of the state is about 5000 feet. The lowest level is the valley of Snake River, which at Boise is 2000 feet above sea-level. In the south are a number of irregular ridges largely shaped by erosion, locally known as the Bear River Mountains, Goose Creek Mountains, South Mountains, Blackfoot Range, &c. A part of the plateau-region is included in the great lava flood which occurred in comparatively recent geological times, and which is still noticeable in the cliffs and mesas that diversify the surface.

SNAKE RIVER—also known as Shoshone, and as Lewis River—drains by far the largest part of the state. Its course (about 850 miles in length) lies in a valley remarkable for scenic beauty. In various places the valley widens out into broad savannahs susceptible of a high degree of cultivation. The open valleys alternate with narrow cañons through which the river flows in dalles and cataracts. This river is navigable some way up from Lewiston (which is accessible to sea-going ships), and from the mouth of Powder River to Salmon Falls, a distance of 200 miles. Salmon River, one of the largest tributaries of Snake River, drains the central part. The character of its valley is much like that of the latter. Clearwater, Payette, Boise, Weiser, Bruneau, Malade, and Goose rivers are tributaries, important mainly for the fertile lands which flank their courses. Pend d'Oreille, or Clarke's Fork, drains Northern Idaho. Its main tributaries are Cœur d'Alene and St Joseph rivers. Dalles, cascades, and cataracts characterise all the rivers of the state. Shoshone Falls almost rival those of Niagara in grandeur.

There are two lake-regions: one in the panhandle, the other in the south-east. The former includes Pend d'Oreille, Cœur d'Alene, and Priest (or Kaniksu) lakes; the latter, John Gray's and Bear lakes. The surplus waters of Bear Lake flow through Bear River into Great Salt Lake. These lake-regions abound in game, and are perhaps the finest hunting-grounds in the United States.

Among the wild animals are the grizzly bear, two species of brown bear, the black bear, raccoon, panther, badger, wolf, fox, and coyote. Fur-bearing animals are represented by the lynx, mink, and beaver. The bison, once common, is no longer seen. The moose and elk are occasionally met with. Deer of two species and antelope are numerous. The Rocky Mountain sheep is found in the Cœur d'Alene Mountains.

Vegetation is abundant in the northern and central parts, but somewhat deficient in the arid lands of the south. Forests of conifers, chiefly lodge-pole pine of small diameter but thick in growth, with several species of cedar and spruce, cover the western slopes of the Bitter Root and Cœur d'Alene mountains. These forests embrace a wealth of timber not surpassed by any other equal area on the continent. Fir, tamarack, and larch are also abundant. In the central and southern part the forests give place to extensive mesas overgrown with sage brush, and rolling lands covered with bunch grass. The river-valleys are dotted with occasional groves of cottonwood and

thickets of wild fruits, such as the blackberry, wild currant, salal, and fox-grape.

The mineral wealth of the state consists chiefly in its mines of silver, lead, gold, zinc, copper, and other metals. Coal (lignite) is found in various parts of the state. In the basin-area of the south-east soda, gypsum, sulphur, and minerals common to lacustrine deposits abound. Mineral springs are numerous.

The climate is exceedingly healthy. The extremes of temperature rarely range beyond 0° and 90° F., except in regions of great altitude. The rainfall, abundant in the north, is deficient in the south, so that irrigation is necessary to ensure full crops. It is estimated that 10,000,000 acres are susceptible of irrigation. Grain-farming and an active fruit-culture are confined to the narrow river-valleys, and the state is much better adapted to stock-raising than to cultivation. The crops (wheat, potatoes, hay, &c.) are largely moved by wagon-trains and river-boats, but there are about 3000 miles of railway. The chief manufactures are those connected with lumber and grain.

Idaho, constituted a territory in 1863, received its present limits in 1888, and in 1890 was raised to the rank of state. Gold was first found in 1852, and raised in paying quantities in 1860. The population, distributed mainly along the river-valleys of the southern and western parts, was 14,999 in 1870, 32,610 in 1880, 88,548 in 1890, 161,772 in 1900, 325,594 in 1910, and 431,866 in 1920. There are some 3000 Indians. Women were admitted to full suffrage in 1896. Education flourishes. There is a state university at Moscow, besides several other colleges. Boise (21,400) is the capital and chief city; Pocatello has 15,000 inhabitants.

Idar. See EDAR.

Iddesleigh, EARL OF, Conservative statesman, better known as Sir Stafford Northcote, was born of a very old Devonshire family on 27th October 1818, and was educated at Eton and Balliol College, Oxford, gaining a first-class in classics. He began public life in 1842 as private secretary to Mr Gladstone, who was then President of the Board of Trade. In 1847 he was called to the bar, and four years later succeeded his grandfather as eighth baronet. He was secretary to the commissioners of the Great Exhibition. In 1855 he entered parliament as Conservative member for Dudley, and in 1858 was elected for Stamford, in 1866 for North Devon, for which he sat until 1885. He was Financial Secretary to the Treasury in Lord Derby's ministry of 1859, and in 1866 became President of the Board of Trade. He had already demonstrated his knowledge of finance by his treatise entitled *Twenty Years of Financial Policy*, published in 1862. While at the India Office in 1868 Sir Stafford Northcote was charged with the responsibility of the Abyssinian Expedition, which under his auspices was carried to a successful issue. In 1871 his old ally Mr Gladstone appointed him British Commissioner to the United States for the adjustment of the *Alabama* difficulty. Sir Stafford Northcote was Chancellor of the Exchequer in Mr Disraeli's ministry of 1874, and among other useful measures which he introduced, in addition to his budgets, was the Friendly Societies Bill of 1875. In the debates on Eastern affairs and the Suez Canal he rendered signal service to the government. When Mr Disraeli went to the Upper House Sir Stafford succeeded to the leadership in the Commons, and his task was very arduous in connection with the Irish debates. Upon the death of Lord Beaconsfield he became joint leader of the Conservative party with the Marquis of Salisbury. His management of the Tories in the Lower House during

several years of opposition elicited warm eulogiums. When Lord Salisbury came into power in 1885 Sir Stafford Northcote was raised to the peerage and was appointed First Lord of the Treasury. In Lord Salisbury's second ministry Lord Iddesleigh was Foreign Secretary; but he resigned this post early in January 1887. On the 12th of the same month he died very suddenly. See his collected *Lectures and Essays* (1887), and the *Life* by Andrew Lang (1890).

Idea. This word has borne very distinct meanings in the history of philosophy. Down to the 17th century it had the signification given to it by Plato, and referred to the Platonic doctrine of eternal forms existing in the Divine mind, according to which the world and all sensible things were framed. The word was used in this sense in literature as well as in philosophy down to the 17th century, as in Spenser, Shakespeare, Hooker, and Milton.

In speaking of the mental representation of external things, Descartes, instead of employing the various terms *image*, *species*, *phantasm*, &c., which had been the words formerly in use for that particular signification, used the word *idea*. In this he was followed by other philosophers, as, for example, Locke, who states that he has adopted the word to stand for 'whatever is the object of the understanding, when a man thinks.' Thus, the mental impression that we are supposed to have when thinking of the sun without seeing the actual object is called our *idea* of the sun. The *idea* is thus in contrast with the sensation, or the feeling that we have when the senses are engaged directly or immediately upon the thing itself. But the word has been very variously used, as by Berkeley, Hume, Kant, Hegel (see these articles). For innate ideas, see COMMON SENSE, LOCKE.—*Idealism* is a term used almost as variously as *Idea*. Idealism may be a theory concerning our knowledge of external existence, restricting mind directly to knowledge of its own state, whereas the opposed *realism* implies a direct knowledge of the external. Idealism may be also a theory as to the nature of the universe, and be spoken of (rightly or wrongly) as *subjective idealism*, as in Fichte (q.v.), *critical* as in Kant (q.v.), or *absolute* as in Hegel (q.v.). See also BERKELEY. In the medieval controversies between nominalism and realism, realism was a kind of idealism (see NOMINALISM). Idealism is also used for ethical and æsthetic systems which adopt an ideal standard of estimating character, human possibilities, or subjects in art (see REALISM). The word realism has a further peculiar sense in Herbart (q.v.).

Ideler, CHRISTIAN LUDWIG, astronomer and chronologist, was born 21st September 1766, near Perleberg, in Prussia, and, after holding various offices, received a professorship at the university of Berlin in 1821. He wrote several valuable works on chronology, and died August 10, 1846.

Idea. See CALENDARS.

Idiocy (or *Amentia*).—For general purposes the definitions of the classes of mental defectives in the Mental Deficiency Acts of 1913 are sufficiently descriptive. They are as follows:

(a) Idiots: persons so deeply defective in mind from birth or from an early age as to be unable to guard themselves against common physical dangers.

(b) Imbeciles: persons in whom the early or congenital mental defect, though not amounting to idiocy, is yet so pronounced that they are incapable of managing themselves or their affairs, or, in the case of children, of being taught to do so.

(c) Feeble-minded persons, in whose case there exists from birth or an early age mental deficiency

not amounting to imbecility yet so pronounced that they require care, supervision, and control for their own protection or for the protection of others; or, in case of children, those who by reason of mental defect appear to be permanently incapable of receiving proper benefit from the instruction in ordinary schools.

(d) Moral imbeciles: persons who from an early age display some permanent mental defect, coupled with strong vicious or criminal propensities on which punishment has had little or no deterrent effect.

There are two kinds of mental deficiency—primary and secondary. The primary class, which forms from 80 to 90 per cent. of the whole, are the products of faulty development inherent in the germ plasma. The secondary class are the result of some injury to the brain occurring at birth or in infancy. These injuries may be mechanical, the result of hæmorrhage or following such diseases as scarlet-fever, measles, and meningitis. It may also be caused by defective secretion of the pituitary or thyroid glands (cretinism) and by deprivation of the special senses, as in early-occurring blindness, deafness, &c. Epilepsy is a frequent concomitant of mental defect, but it is then to be regarded as a complication rather than as a variety in itself.

There are great varieties of idiocy and imbecility. Some of the lowest have no speech, no power of distinguishing between one person and another, no affection or hatred, no feelings of pleasure or pain, no power to take care of themselves, and can never be taught any of these things. In body such idiots are dwarfish, misshapen, and ugly. This being the condition of the lowest varieties, they rise gradually in the scale till many imbeciles are beautiful in features, and reach normal bodily development, but are slightly wanting in some essential mental faculty, in intelligence, or in affection or control, or self-guidance. The mental deficiency is in by far the majority of idiots and imbeciles accompanied by corresponding bodily weaknesses of some sort.

Idiots and imbeciles differ much in their capacity for further development under even favourable circumstances. Some can be greatly elevated towards the standard of average humanity, and can even be rendered fit to earn their own livelihood in simple trades or manual labour, while others cannot be in any way improved. They are especially subject to certain bodily diseases of degeneration, such as scrofula, consumption, rickets, and diseases of deficient nutrition generally. Two-thirds of idiots die of consumption. The great aims in treatment are to improve the bodily nutrition, the nervous and muscular action, and the habits; to teach co-ordinated movements and simple employments, such as gardening, mat-making, carpentering, &c., and to evolve the possible intelligence by an education through the senses. Some of them have one faculty or capacity fairly or even extraordinarily developed, while the general mental power is weak. Some are good musicians. Some can calculate well, while others are ingenious in constructiveness.

The two chief kinds of primary mental defectives are Microcephalics and Mongolians. A microcephalic idiot is a person whose skull is less than 17 inches in its greatest circumference. The brain is of course correspondingly small. As a rule microcephalics possess all their senses—i.e. sight, hearing, &c.—and exhibit a general vivacity and restlessness of conduct with a tendency to mischief. Most of them are incapable of acquiring education. Mongolians are so called because of the striking similarity of their features to the Mongol type. The head is rounded, the hair fair to brown, the eye-

lids narrow, oblique, and sloping downwards and inwards; the tongue is red and furrowed, and the hands and feet are broad, flabby, and clumsy.

The varieties of secondary defectives are very numerous, and include cretins, epileptics, and those afflicted with the various forms of paralysis.

Feeble-mindedness, when not accidental, is always hereditary. It is a well-established fact that if both parents are healthy and free from neuropathic taint their offspring is healthy, and that when both parents are mentally defective the offspring is also defective.

The Mental Deficiency Acts passed for the purpose of making better provision for the care and education of defectives came into force a few months prior to the outbreak of the European War in 1914. Consequently their provisions have not come into full effect, with the result that up to the present time only about 14,000 defectives are under care in the United Kingdom. That figure does not include the large number of defective children, chiefly in urban centres, who are educated at the expense of educational authorities in special schools or classes. The number at present under care is a mere fraction of those who will ultimately come under the operations of the acts when the financial resources of the country permit greater freedom of expenditure.

Idiosyncrasy. See ANTIPATHY.

Ido, a simplification of Esperanto, proposed in 1907. See a book by the Marquis de Beaufront (1919).

Idocrase. See VESUVIAN.

Idolatry. See IMAGES.

Idria, a mining town in Italian Carniola, celebrated for its quicksilver mines (discovered in 1497), is situated 1093 feet above sea-level in a deep, cauldron-shaped valley, on a river of the same name, 23 miles W. by S. of Laibach. Many of the women are employed in lace-making. Pop. 6000.

Idris, a mythical figure in Welsh tradition, supposed to have been at once a giant, a prince, and an astronomer. On the summit of Cader Idris (q.v.) in Merionethshire may be seen his rock-hewn chair, and an ancient tradition told that any Welsh bard who should pass the night upon it would be found next morning either dead, mad, or endowed with supernatural poetic inspiration. This tradition forms the subject of a fine poem by Mrs Hemans; the gigantic size of the chair is alluded to in Tennyson's *Geraint and Enid*.

Idrisi. See EDRISI.

Idumæa. See EDOM.

Idun, or IDUNA, the name of a goddess of the northern mythology. She was the daughter of the dwarf Svold; but being received among the Æsir, she became the wife of Bragi. See SCANDINAVIAN MYTHOLOGY.

Idyll (Gr. *eidullion*, Lat. *idyllium*, 'a little image'), a term generally used to designate a species of poem representing the simple scenes of pastoral life. It is, however, an error to suppose that the idyll is exclusively pastoral; certainly there is no warrant for such a notion in the usage either of the ancients or the moderns. Of the thirty *Idyllia* of Theocritus not more than one-half are pastoral in their character. After the use made of the word by Tennyson in his *Idylls of the King*, which are epic in their style and treatment, and romantic and tragic in their incidents, it becomes very difficult to say what may not be called an idyll.

If, a rocky island in the Gulf of Marseilles, crowned by a castle, the Château d'If, which was built by Francis I. of France, and subsequently used as a state-prison. Here were confined,

amongst others, Mirabeau and the Duke of Orleans (Philip Egalité), not to mention 'Monte Cristo.'

Ifni, a coast region south-west of Morocco, ceded to Spain in 1883, and re-occupied by Spain in 1911. Area, 1000 sq. m.; pop. 20,000, fishers and date-growers.

Iggdrasil. See YGGDRASIL.

Iglau (Czech *Jihlava*), a town of Moravia, is situated 1703 feet above sea-level, on the river Iglawa. It has some old churches (one founded in 799). Its staple industries have always been the manufacture of cloth and woollen goods; glass and tobacco are also manufactured. It has a large trade in corn, flax, wool, cloth, and timber. Pop. 28,000. Here in 1436 the Emperor Sigismund signed the Prague Compactata, after which he was accepted as king by the Bohemians. In the Thirty Years' War it was taken by the Swedes and recaptured by the Imperialists.

Igloolik, an island near the east end of the Fury and Hecla Strait in the Arctic Ocean, is the place where Parry passed the winter of 1822-23.

Ignatieff, NICOLAUS PAULOVITCH, Russian diplomatist, was the son of General Paul Ignatieff, a favourite officer of Alexander II. He was born at St Petersburg on 29th January 1832, and educated in the corps of pages. In 1850 he exchanged from the military to the diplomatic service. In 1858 he induced China to give up to Russia the Amur province; and in 1860, having been appointed ambassador at Peking, he secured for his country from China the southern portion of the Maritime Province lying east of the Amur. Between the two treaties by which Russia thus gained footing on the Pacific, Ignatieff concluded with Khiva and Bokhara commercial treaties advantageous to his own country. In 1867 he was made ambassador at Constantinople, at which court he had represented Russia since 1864. He there acquired considerable influence. The treaty of San Stefano was principally his work; and he was greatly incensed at its revision. As minister of the interior he sought in vain to stamp out Nihilism by force. He was dismissed next year, apparently because of his administrative inefficiency and Pan-Slavist intrigues, and for having shut his eyes to the persecutions of the Jews. He died 3d July 1908.

Ignatius, one of the Apostolic Fathers, about whom information is but scanty down to the time of Eusebius, apart from what may be gained from the much disputed epistles associated with his name. From these it may be inferred that he was converted to Christianity in mature life, and that his earlier life had been such as to fill his later years with remorse and give an unusual intensity to his religious convictions. The name is Roman; the second name, Theophoros, is merely a second name and not a title of honour ascribed to the saint. Origen makes him the second of the Antiochene bishops, and in Jerome's revision of the *Chronicon* of Eusebius he is stated to have been, with Papias and Polycarp, a disciple of St John. The usual date for his accession is 69 A.D., and of his martyrdom 107, but all that can be said with certainty is that his martyrdom fell about 110. The letters show that he was condemned to the wild beasts at Antioch, and that he was carried to Rome by a maniple of soldiers merely for the execution of his sentence. On the journey he was joined at Smyrna by representatives from the churches of Tralles, Magnesia, and Ephesus. Here he wrote four letters which are extant; three to the churches whose delegates had met him—the Ephesians, the Magnesians, and the Trallians; the fourth, to the church of the Romans, whither he was journeying. The first three are mainly con-

cerned in enforcing lessons of doctrinal truth and ecclesiastical order; the fourth is occupied almost entirely with the thought of his approaching martyrdom. Next from Troas he wrote three letters: the first and second to the churches of Philadelphia and Smyrna, which he had just visited; the third to Polycarp, bishop of the latter. The general topics treated are the same as in the first three, but special charges are laid upon Polycarp to exhort the brethren at Antioch. We next hear of him at Philippi, as we learn from Polycarp's extant reply to the Philippian, who had evidently asked Polycarp for copies of the letters of Ignatius—not improbably the very cause of their preservation. Beyond this point we know nothing more of Ignatius save that at Rome he earned his martyr's crown.

About the close of the 4th century we meet the persistent statement that the relics of Ignatius had been carried from Rome to Antioch, and we find October 17 fixed as the day of his martyrdom. The bones were finally deposited in the Tychæum or Temple of Fortune, which henceforward became known as the Church of Ignatius. His reputation was great, as is evinced by the epistles forged or interpolated in his name; the legendary acts of martyrdom, which give the unhistorical but well-known interview with Trajan; the translation of his letters into Syriac, Coptic, and Armenian—honoured especially by the Monophysites, who fancied they found support in them for their distinctive tenets. And from the close of the 16th century the Jacobite patriarchs of Antioch have regularly assumed the name of Ignatius on their accession to the see.

The Ignatian epistles exist in three different forms or recensions. The *first* of these contains three epistles alone: to Polycarp, to the Ephesians, and to the Romans. It is extant only in a Syriac version. The *second* presents these three epistles in a fuller form, and adds to them four others: to the Smyrneans, Magnesians, Philadelphians, and Trallians. Besides the original Greek this form is found in Latin, Armenian, Syriac, and Coptic translations, although only fragmentarily in the last two. The *third* contains the seven epistles already mentioned in a still longer form, together with six others—a letter from Mary of Cassobola to Ignatius, and letters from Ignatius to Mary of Cassobola, to the Tarsians, the Antiochenes, to Hero, and to the Philippian. This recension is extant both in Greek and in a Latin translation. These three it is now usual to call the *Short*, *Middle*, and *Long* recensions. As will be seen, of the twelve Ignatian epistles (excluding that of Mary to Ignatius) three occur in three different forms, four in two and five in one. The long recension is now universally condemned as spurious. More serious is the dispute between the remaining two, which are often spoken of, from their editors, as the Curetonian (*Short*) and the Vossian (*Middle*) versions. The Curetonian long held the field, but the genuineness of the Vossian letters is now the prevailing belief.

The *Short Form*, represented only by a Syriac version, was first published by the Rev. W. Cureton in 1845, from MSS. recently brought to the British Museum from the Nitrian desert. Not only are the epistles fewer in number, but shorter and more abrupt. Their upholders believe the Greek form an expansion and corruption of the lost Greek originals of these Syriac letters; while their opponents think the Syriac an abridgment of the Greek.

The *Middle Form* was first published in the Latin version (made perhaps by Robert Grosseteste), by Ussher (Oxford, 1644), from two MSS. discovered in England; the original Greek, by Isaac Voss (Amsterdam, 1646), from a Medicean MS., the epistle to the Romans alone excepted, which was first published by Ruinart (Paris,

1639). The Armenian version appeared at Constantinople in 1783. These may now be accepted with some confidence as the seven epistles of Ignatius mentioned by Eusebius, which were translated into Syriac soon after his time, and of which the Curetonian epistles are merely an extract.

The Long form in its Latin version was printed by J. Faber Stapulensis (Paris, 1498); in the Greek version by Valentinus Paccus (Dillingen, 1557). These epistles are supposed to have been interpolated and extended by the pseudo-Ignatius in the later half of the 4th century.

The chief differences in substance of these three forms of the Ignatian epistles are these: the Curetonian text contains no quotation from the Old Testament, and very few from the New, while the Vossian contains a considerable number of quotations, and the Long a large number. Again, the last also contains many allusions to religious institutions not in existence in a mature state before the 4th century, as well as plagiarisms from preceding writers and perceptible differences in doctrinal teaching. There is a tendency to maintain the supremacy of the Father and to make the Son's agency dependent. Indeed, many passages savour distinctly of Apollinarianism, yet the general bearing of the language leans faintly to the Arian side. The whole might well be an eirenicon palmed off by a pious fraud upon the name of a venerated primitive father of the church. The style and expression throughout drive us to the conviction that the six additional letters come from the same hand which interpolated the seven.

Again, the Vossian letters are found to be distinctly antagonistic to Docetism. Indeed, a characteristic note of Ignatian theology throughout is the accentuation of the twofold nature of Christ—his deity and his humanity. The advocacy of the episcopal office appears definitely in the *Short* no less than the *Middle* form; and the abridgment must have been made rather for purposes of edification or practical convenience rather than for Monophysite reasons, as C. Wordsworth maintained, or for any other doctrinal purpose. In short the abridgment theory is much more rational and easy than the expansion theory, and if we are to accept the latter we must maintain, says Lightfoot, that the pseudo-Ignatius was a prodigy of minute observation, of subtle insight, of imitative skill, of laborious care, which is probably without a parallel in the history of literary forgeries, and which assuredly was an utter impossibility among the Christians of the 2d and 3d centuries.

The prominence and authority of the episcopal office in the Ignatian epistles has proved a grave stumbling-block to many scholars. It is certainly sufficiently clear throughout, yet it is merely as the embodiment of the idea of order and the guarantee of unity within the church. It is not upheld exclusively as against other forms, while all tinge of sacerdotalism is absent, as well as such an argument as that in Irenæus, who lays stress on the apostolic succession as a security for its faithful transmission. Nor is it autocratic by any means, while its spread is not yet uniform throughout Christendom, as at Philippi, for example. Evidence of a localised episcopate within the Gentile churches is absent, and nowhere is there any trace of the notion of a distinct diocese, while there is no reference to any developed ritual of public service. Six of the epistles are full of the necessity of obedience to bishops, which is alone wanting in the seventh, that addressed to the Romans, who it may legitimately be inferred had not yet adopted the form of government which Ignatius elsewhere commended with such warmth.

See Cureton, *Antient Syriac Version of the Epistles of S. Ignatius*, &c. (1845), and his *Corpus Ignatianum*

(1849); the works in his support by Bunsen, A. Ritschl, R. A. Lipsius, and those against his theory by Baur and Hilgenfeld, who denied the authenticity of any recension. A fatal blow to Cureton's theory was dealt by Zahn, *Ignatius von Antiochien* (1873), which won over Lipsius and Lightfoot. See also Lightfoot's *Apostolic Fathers*; Harnack's *Chronologie der altchristlichen Literatur* (1897); Von der Goltz's *Ignatius von Antiochien* (1894); Srawley's English translation (1919).

Ignatius, FATHER, was the name 'in religion' of Joseph Leycester Lyne (1837-1908), born in London, who received deacon's orders in 1860, and from 1862 laboured to revive the Benedictine order within the communion of the Church of England. An eloquent preacher, he received priest's orders in 1898 from an oriental bishop, and ultimately settled near Llanthony Abbey in Monmouthshire. See his *Life* by the Baroness de Bertouch (1904).

Ignatius' Beans, SAINT, the seeds of the *Strychnos Ignatii* (otherwise *Ignatia amara*), a tree of the natural order Loganiaceae, nearly allied to that which produces *Nux vomica* (q.v.), a native of Cochin-China and of the Philippine Islands. The seeds contain *strychnia*, and their medicinal uses are similar to those of *nux vomica*.

Ignatius Loyola. See LOYOLA.

Igneous Rocks are those which have been erupted from the heated interior of the earth: hence they are also termed *eruptive rocks*. Petrologically they may be grouped under two heads—*crystalline* and *fragmental*. The crystalline division includes many rocks which are rather vitreous or glassy than crystalline, while a large number are composed partly of crystalline and partly of non-crystalline materials. No quite satisfactory classification of the 'crystalline' igneous rocks has as yet been possible, perhaps the most convenient being that which is based on the nature of the principal rock-forming minerals. Thus, those in which orthoclase (see FELSPAR) is a dominant ingredient are grouped together as *Orthoclase rocks*. In another large class plagioclase-feldspars play a principal part, and thus we have the *Plagioclase rocks*; and so in like manner *Nepheline* and *Leucite* rocks, and *Olivine* and *Serpentine* rocks.

(1) *Orthoclase Rocks*.—Some of these rocks contain much free silica (Quartz, q.v.), while others contain little or none. They are thus divided into two groups—*Quartziferous* and *Quartzless*. Under the first group come *Granite*, *Quartz-porphry*, and *Liparite*, while under the second are ranged *Syenite*, *Orthoclase-porphry*, and *Trachyte*. Some of these rocks are holocrystalline—i.e. composed entirely of crystalline ingredients, as granite and syenite; others, such as liparite and trachyte, are only semi-crystalline—they contain in addition to crystalline constituents a larger or smaller proportion of non-differentiated mineral matter. *Obsidian* and *Pitchstone* are vitreous species of orthoclase rocks which consist almost entirely of volcanic glass. Other kinds of orthoclase rocks have been recognised by petrologists, but those mentioned are the most important.

(2) *Plagioclase Rocks*.—Most of the rocks in this division are distinguished by their basic character—that is to say, they contain generally less silica than orthoclase rocks. The most important species are *Diorite* (a crystalline granular aggregate of plagioclase and hornblende), *Andesite*, *Porphyrite*, *Basalt*, and *Gabbro*. The holocrystalline character is seldom met with in this division; it occurs, however, in diorite and gabbro. The other species mentioned usually contain some admixture of non-differentiated mineral matter. Vitreous varieties also occur in this division. See BASALT.

(3) *Nepheline and Leucite Rocks*.—The rocks included under this head closely resemble the basalt

rocks of the preceding division, plagioclase being substituted in whole or in part by nepheline or leucite or by both. See BASALT.

(4) *Olivine and Serpentine Rocks*.—These are generally rather basic rocks. The olivine rocks proper, or *Peridotites*, as they are called, contain olivine as their principal constituent. They often show more or less alteration, the olivine being replaced in whole or in part by Serpentine. Some olivine rocks, indeed, have been completely altered into serpentine.

The *fragmental* igneous rocks consist of the loose ejectamenta which have been erupted from volcanic orifices. These rocks are frequently consolidated, and when fine-grained it is sometimes

Fig. 1.—Neck filled with Fragmental Igneous Rock.

difficult without the help of the microscope to distinguish them from compact crystalline igneous rocks. Some account of these rocks will be found under AGGLOMERATE, TUFF, VOLCANO.

Igneous rocks, when looked at from the point of view of the student of structural geology, are classified in an altogether different way. It is not only necessary to know the petrological character of a rock—we must discover something of its history. Was it extruded at the surface like the ejecta of modern volcanoes, or did it cool and consolidate below ground? Thus two kinds of igneous or eruptive rocks are recognised by geologists: (1) *Volcanic rocks*, consisting of lavas, tuffs, &c., which have been ejected at the surface, either upon the land or under water; (2) *Plutonic* or *Hypogene rocks*, which, whether consisting of crystalline or fragmental materials, have not been so extruded, but are now exposed owing to the denudation of rock-masses underneath which they were formerly concealed. The volcanic rocks are often termed *contemporaneous*—i.e. they belong to the same geological age as the strata with which they are *interbedded*. On the other hand, the *plutonic* rocks are described as *intrusive* or *subsequent*, because they have been *intruded* amongst, and therefore must be *subsequent* in date to the rocks with which they are in contact.

(1) *Contemporaneous Igneous Rocks*.—These consist of crystalline (lava-flows) and fragmental rocks (tuffs, &c.), and are simply the products of former volcanic action. They are met with at all geological horizons from the oldest down to the most recent period. Sometimes they indicate the former existence of small isolated 'puys' (see VOLCANO), from which it may be only a single eruption took place; at other times they are obviously the products of much more powerful and long-continued volcanic action. Many of the hill-ranges of central Scotland (for example, Sidlaws, Ochils, &c.) are built up of successive lava-flows with associated tuffs, which have been ejected from vents in the manner of modern volcanic eruptions. In some regions, however, there occur vast successions of lava-flows, covering immense areas, which do not appear to have been erupted from isolated vents, but are believed to have welled up along the line of great fissures, and to have poured in wide floods over the surface, so as eventually to form extensive plains or plateaus. The rocks of such 'fissure-eruptions' consist usually of basalt, with basalt-tuff or Palagonite. The basalt plateaus of the western territories of North America, of Iceland and the Faroes, of the Deccan (India), and of Abyssinia are good examples; while in Antrim

and in many of the western islands of Scotland fragments of similar plateaus may be studied.

An interbedded or *contemporaneous* lava-form rock may often be distinguished from an *intrusive*

Fig. 2.—Contemporaneous and Intrusive Igneous Rocks :
c, c, contemporaneous trap-rocks ; t, t, contemporaneous fragmental igneous rocks ; p, n, d, intrusive igneous rocks.

sheet of crystalline igneous rock by noting that the beds which immediately overlie it show no trace of having been subjected to the action of heat. The upper part of the lava-form rock is not infrequently scoriaceous or amygdaloidal (see AMYGDALOID) in character, and fragments of this crust may occasionally be found in the overlying beds if these chance to be of aqueous origin.

(2) *Intrusive Igneous Rocks*.—These rocks are likewise met with under two forms—*crystalline* and *fragmental*. The *fragmental* intrusive rocks are found only in connection with old volcanic vents. These latter, in countries where volcanic action has been long extinct, no longer exist as crateriform hollows. The upper parts of the cones have all been swept away, and only the stumps remain. These stumps are known as *necks*, by which is understood a more or less cylindrical funnel or volcanic vent filled up either with fragmental or crystalline rock or with both. Such necks vary in diameter from a few yards up to several hundred feet; sometimes they occur upon a line of Dislocation (q.v.) or fault; at other times they have no such connection. The necks now described are probably the relics of comparatively small volcanoes like the puy of Auvergne and the Eifel. Now and again, however, as in some of the hill-ranges of central Scotland, necks of a larger size are met with. These vary from 100 yards or so up to a mile or more in diameter, and are usually plugged up with crystalline igneous rock, although fragmental rock also is occasionally present. Such necks seem to be the stumps of great volcanic vents, from which the lava-form and fragmental igneous rocks of the surrounding neighbourhood were ejected. Good examples occur at Arthur's Seat, Largo Law, Dumgoyne and Dumfryn, &c. *Bosses* is the term applied to irregular-shaped masses of crystalline igneous rocks, which appear to be for the most part of deeper-seated origin than those of the necks just referred to. The rocks of these bosses are usually more or less coarsely crystalline, and often have a granitoid aspect, such as granite, syenite, gabbro, &c. Bosses usually cover a considerably wider area than necks, and it has been conjectured that they are merely the most deeply seated portions of ancient volcanoes—the reservoirs from which molten matter was pumped up to the surface. *Intrusive Sheets* are masses of crystalline

Fig. 3.—Intrusive Sheet and Dykes :
i, igneous intrusive sheet ; d, d, dykes ; s, s, sedimentary strata.

igneous rock which have been erupted between the planes of bedding of pre-existing strata. They are

never scoriaceous or slaggy, and are generally markedly crystalline in texture, especially when the sheet is thick. Their intrusive character is often betrayed by the baked appearance of the beds which overlie them; by the fact that they seldom keep quite to one and the same plane, but sometimes break across the overlying beds and continue their course along a somewhat higher horizon; and by the veins and protrusions which not infrequently proceed from them. *Dykes* are vertical wall-like sheets of igneous rock, which may vary in thickness from a foot or so up to 30 yards or more. They often run persistently in one direction for many miles. Occasionally they divide into two or more branches, and now and again they send out veins into the surrounding strata. The rock most frequently met with in such dykes is basalt. Sometimes dykes rise along the lines of faults, but this is by no means general. *Veins* is the term applied to the more irregular, winding, branching, and tortuous smaller intrusions of igneous rock. They may consist of any kind of crystalline rock. Dykes and veins are frequently found proceeding in all directions from bosses, as in the case of granitic masses. From the smaller puy-like necks also veins and dykes have occasionally been injected into the surrounding rocks, while these and extensive sheets may often be traced proceeding from the larger kinds of necks. The rocks surrounding bosses, and traversed by veins, are often highly metamorphosed.

Ignis Fatuus (Lat. *ignis*, 'fire,' *fatuus*, 'foolish') is a luminous appearance of uncertain nature which is occasionally seen in marshy places and churchyards. The phenomenon has been frequently described, but it has been observed so rarely in favourable circumstances by scientific men that there is no satisfactory explanation. The light usually appears in autumn evenings shortly after sunset; it is common in the north of Germany, in Italy, in the south and north-west of England, and on the west of Scotland, but it has been noticed in many other countries.

Descriptions of ignes fatui vary so much that several different phenomena have evidently been included under the name. The light usually resembles a flame, and is often mistaken at first for the light of a lantern, but seen more closely the colour appears as bluish, reddish, greenish or yellowish, merging into purple, but never a clear white. Some observers describe the flame as fixed in position, shining steadily either close to the ground or a few feet above it, and illuminating the surrounding reeds and grass. Others have seen it in motion bounding rapidly over the country, and sometimes rising high in the air. The light has been seen to divide repeatedly into several smaller flames, which describe complicated movements, advancing, retiring, and combining. The moving light is said to recede from an observer who approaches it, but to follow him if he retires from it.

Some supposed appearances of the ignis fatuus have been proved to be the lights of distant houses seen through trees; others are almost certainly due to luminous insects, such as the glow-worm, or to the phosphorescence of decaying vegetable matter. St Elmo's Fire (q.v.) has also been confounded with it. But setting all these possible cases aside, both fixed and moving ignes fatui have been proved to exist. It is said that paper has been ignited by the flame, and if this be so there must be at least two similar phenomena of different nature. In 1859 List in north Germany passed his hand through the luminous appearance and felt no warmth; near the same locality at a later date Knorr held the metal tip of a walking-stick in the flame of a fixed ignis fatuus (which he could not himself touch on

account of the marsh) for a quarter of an hour, but the metal was not warmed. In the former instance a puff of air extinguished the flame, and a very slight explosion was heard when it reappeared; in the latter a strong waft of air only made it flicker slightly, and a light breath produced no effect. No odour was perceptible.

The common hypothesis that *ignis fatuus* is the flame of burning marsh-gas, CH_4 , is untenable, for although this gas is produced abundantly in many marshy places it cannot ignite spontaneously. The more plausible suggestion that phosphuretted hydrogen, PH_3 , which is spontaneously inflammable, might be produced in churchyards or marshes where there is decaying animal matter, does not account for the effect observed by the German physicists, since no gas can burn without giving out heat, and that particular gas has a very penetrating and characteristic smell. Nor could a burning gas, except on the most extravagant assumptions, bound over the country like a ball of fire for half an hour at a time. The early supposition of a phosphorescent vapour is more reasonable, although excepting that of free phosphorus, which could not occur in nature, no such vapour is known to exist. The phenomenon was undoubtedly more common a century ago than it is now, and its disappearance in many localities may be directly traced to the draining of fens and marshes.

Popular names—such as Will-o'-the-Wisp, Jack-a-Lantern, Spunkie, and Corpse-Candle—abound, and are connected with many stories of travellers mistaking the marsh lights for a cottage window, and being decoyed into dangerous places, often with fatal results. A German legend identifies the will-o'-the-wisp with the soul of an unbaptised infant; an Irish, with a soul broke out of Purgatory. For the folklore of the subject, see *Notes and Queries*, *passim*.

Ignoramus (Lat., 'we do not know'), the word formerly written by a grand-jury on the back of an indictment, meaning that they rejected it. The word is now used most commonly as a synonym for a blockhead.

Ignorance (*Ignorantia juris*) is held in law to be no excuse for any breach of contract or duty, nor for crime or other offence. It is absolutely necessary to start with this maxim, otherwise it would be quite impossible to administer the law; for if once a contrary maxim were allowed it would not only be a premium to ignorance, but would lead to endless and abortive inquiries into the interior of a man's mind. Ignorance of a fact, however, is a different thing. Another kindred maxim of the law is that every man intends the consequences of his own act. Thus, if he shoot at or give poison to a person it is presumed that he intended to kill such person. So, if he leave a trap-door open in a street or thoroughfare it is held that he intended people to fall into it and be injured. There is, however, a doctrine called *bona fides*, which, in the case of petty offences punishable by justices, often tempers the strict and rigid application of the maxim, *ignorantia juris neminem excusat*; and even in crimes a judge always takes into consideration, when passing judgment, whether the prisoner or defendant was an ignorant or intelligent person.—In Catholic theology, a man is never excused for sin, whether of omission or of commission, on the plea of ignorance which he can be fairly expected to overcome, of 'vincible' or wilful ignorance; whereas 'invincible' ignorance, which a man could not help or abate, altogether excuses from guilt.

Igalada, a town of Spain, 32 miles NW. of Barcelona, on the west side of Mount Montserrat.

It carries on manufactures of cotton and woollen goods and firearms. Pop. 12,500.

Iguana, a genus typical of the Iguanidae, a family of thick-tongued lizards representing in the New World the Agamidae of the Old. The family comprises fifty-six genera, most of which are found in tropical America. They are slender and lizard-like in form, have distinct eyelids, the tympanic membrane usually free, the tail long and compressed, the toes free, five on each limb, and ending in a sharp claw. They are arboreal in habit, and feed chiefly on leaves and fruits, but will also eat insects. The genus *Iguana* includes five species, found in the West Indies and South America, and all characterised by a pyramidal head, a pouch of skin under the throat, and an upright comb of pointed teeth extending along the back from the neck to the tip of the tail. The best known is the Common or Green Iguana (*I. tuberculata*), which has a very large pouch, is predominantly of a beautiful green colour, and grows to a length of from 3 to 5 feet. This iguana lives usually in trees near a stream, climbing with great ease, and moving rapidly along the branches, but taking readily to the water, where it swims by means of its tail.

Common Iguana (*Iguana tuberculata*).

Its flesh is white and tender, and is much esteemed for food. It is sometimes caught by noosed cords, sometimes tracked to its burrow by dogs trained for the purpose. The eggs are about the size of those of a pigeon, but have no hard shell, and are laid in the sand. They also are used as food. Other species of iguana and their eggs are eaten by those, as Darwin says, 'whose stomachs soar above all prejudices.' Other important genera are *Anolis*; *Cyclura*, one species of which, *C. lophomus*, is called the 'great Iguana' of Jamaica; *Amblyrhynchus*, the marine lizard; *Phrynosoma*, the 'horned toads'; and the Basilisks (*q.v.*). See **LIZARD**; Boulenger, *Brit. Mus. Cat. of Lizards*; (shadow, *Camb. Nat. Hist.* (viii. 1901); Leighton, *British Lizards* (1904). See also **MONITOR**.

Iguanodon (*Iguana*, and Gr. *odon*, 'tooth'), a genus of remarkable gigantic dinosaurian reptiles, more abundant in the Wealden beds of Kent, Sussex, and the Isle of Wight than any other genus of associated saurians. Their singular structure, differing in many important particulars from any known reptile, long caused great diversity of opinion as to their true position. Dr Mantell, their original discoverer and learned expounder (1822), first knew of their existence from some enormous bones, which, notwithstanding their

colossal size, he considered reptilian. A large tooth next turned up, whose smooth-worn crown attested its having belonged to a herbivorous animal. Numerous other specimens of teeth were in process of time discovered, and Dr Mantell found that they corresponded in a remarkable manner with the teeth of the small American lizard, the iguana, although they exhibited very striking and important differences. The

Fig. 1.—Front and side view of a Tooth of the lower jaw of the Iguanodon, about two-thirds natural size.

first guesses as to the creature's size, founded on fragmentary materials, varied vastly; Mantel suggesting a length of 70 feet, Owen of 28. An extraordinary find of iguanodonts simplified this and other questions as to the structure. In 1878 there were found at Bernissart, in Belgium, between Mons and Tournai, the remains of about twenty-three specimens, belonging to two well-marked species; only two other species having till then been proposed. Further discoveries have since been made, and now twenty-three complete skeletons are exhibited in the Brussels museum. The length of different species ranges from 16 to 32 feet.

The structure of the skeleton is very remarkable. The front parts of both upper and lower jaws were without teeth, and suggest a hollow, beak-like arrangement; possibly the creature had a long prehensile tongue. In many respects there are striking resemblances between the structure of the ornithomimid Dinosaurians (of which the Iguanodontidae are a family) and that of birds. The vertebral column had joints slightly concave on both surfaces, yet had lofty neural arches; and the sacrum was composed of five ankylosed joints, a structure found in no other reptile. The two fore-legs were small; the hinder limbs were long and strong, raising the body some distance from the ground. The leg terminated in a three-toed foot, which produced the enormous tridactyle impressions on the argillaceous Wealden beds that were for some time considered to be the footprints of huge birds. The teeth of the iguanodon, while bearing

Fig. 2.—Skeleton of Iguanodon.

a general resemblance to those of the iguana, were much more complicated both in external form and internal structure than in any other known

reptile. In all other known reptiles the vertically flat teeth are always sharp-edged, and fitted only to cut off the plants on which they feed; but the worn crowns show that the iguanodon thoroughly triturated its food before swallowing it.

Iguassú, or IGUAZÚ, a tributary of the Paraná (q.v.), separates Brazil from Argentina. In the forest a few miles above the confluence are the famous but little visited falls, comparable in height and volume with the Niagara and Victoria Falls. At the Brazilian Fall the river makes a leap of about 210 feet. Lower down are the Argentine Falls, two cascades of about 100 feet each. The river narrows from 3000 feet above the falls to 400 feet in the gorge. It is proposed to generate electricity for Buenos Aires and other places.

Iguvium. See GUBBIO.

Ihne, WILHELM (1821-1902), born at FÜRTH, taught at Liverpool in 1845-63, and in 1873 became a professor at Heidelberg. He was the author of a famous history of Rome (8 vols.), and of other works on Roman history.

Ihre, JOHAN (1707-80), born at LUND, studied at Uppsala, where he rose to be professor of Belles-lettres and Political Economy (1748). His great work is his *Glossarium Suiogothicum*.

Ikhnoton. See AKHNATON.

Ilchester, a decayed village of Somersetshire, 5 miles NW. of Yeovil, was the principal Roman station of the region, and a flourishing town in Saxon times. Numerous Roman remains have been found here. Birthplace of Roger Bacon, it returned two members till 1832.

Île-de-France, one of the old provinces of France, having Paris as its capital, and now mostly comprised in the departments of Seine, Seine-et-Oise, Aisne, Seine-et-Marne, Somme, and Oise. In the middle of the 9th century it was made a dukedom, and became one of the four constituent fiefs of the French monarchy. The second duke, Odo, commonly called Count of Paris, was crowned king of France in 888. His successors contended for some years for the throne of France; one of them, Hugh Capet, founded in 987 the Capetian dynasty (see CAPET, FRANCE). Île-de-France was formerly the name of Mauritius (q.v.).

Iletzka, a small town in the Russian Kirghiz republic, 48 miles S. of Orenburg, on the Ilek, a tributary of the Ural. Close by is the richest salt-bed in Russia. It was discovered by Pallas in 1769, and visited by Murchison in 1850.

Ileum. See DIGESTION.

Ileus, or ILLIAC PASSION. See COLIC.

Ilex, a tree often named in the Latin classics, the Evergreen Oak or Holm Oak (*Quercus Ilex*). See OAK. It is a native of most parts of the south of Europe and of the north of Africa, often attaining large dimensions, as it sometimes does where planted in Britain. Its leaves are ovate-oblong, acute, leathery, hoary beneath; but they vary much in size, and from being very spiny at the edge to perfect evenness. The bark is very astringent, and is employed for tanning hides in the countries to which the tree is indigenous. Its wood is very hard and heavy, tough, durable, and useful, particularly for axles, pulleys, screws, and whatever is to be subjected to much friction.—In modern botany Ilex is the generic name of the Holly (q.v.).

Ilford, a parliamentary borough of Essex, 7 miles ENE. from London, has large photographic works and paper-mills. The chapel of the 12th-century Hospital of St Mary is of archaeological interest. Pop. 85,000.

Ilfracombe, a watering-place of England, is finely situated on the picturesque rocky coast of

North Devon, on a cove or inlet of the Bristol Channel, 11 miles NNW. of Barnstaple. Its air 'combines the soft warmth of South Devon with the bracing freshness of the Welsh mountains' (Charles Kingsley). This and its fine coast-scenery (geologically and botanically interesting) and its admirable sea-bathing annually attract large numbers of visitors. On the north side of the (good) harbour the pier curves round the base of Lantern Hill, with St Nicholas' Chapel on its peak; to the east is Hillsborough Hill. Ilfracombe was in the 14th century a port of some consequence, and contributed six vessels to the English fleet for the siege of Calais. Pop. 12,000.

Il. See KULJA.

Ilicin, the bitter principle derived from Holly (q.v.).

Iissus. See ATHENS, and ATTICA.

Ilium. See TROY; and for Iliad, see HOMER.

Ilk (O.E. *ylk*, 'the same'), an old form found both in English and Scots meaning the same. Thus, Chaucer has 'this ilk worthe knight' and 'that ilk man.' It is still not unknown in Scotland in connection with family designations; thus, 'Kinloch of that ilk' means 'Kinloch of the estate of that same name,' or 'Kinloch of Kinloch.' 'Of that ilk' is however constantly but absurdly and ignorantly used to mean 'of that description,' as in 'carpet-baggers and politicians of that ilk.'

Ilkeston, a municipal borough (1887) of Derbyshire, near the Erewash River, 9 miles ENE. of Derby, and 20 S. of Chesterfield. The parish church, with a lofty pinnacled tower, has interesting Norman and Early English features. The town-hall was built in 1868. Ilkeston has manufactures of hosiery, lace, silk, and earthenware, with coal and iron mines in the vicinity. In 1251 a charter for holding a market and fair here was granted to Hugh Fitz-Ralph. Pop. 32,000.

Ilkhan, literally 'ruler of tribe or clan' (Turkish *şh*). Specifically the name Ilkhans or Eyllkhanis is used by Europeans to denote the Persian dynasty founded by Hulagu (brother of Kublai) in 1258, and he is (correctly) called by them the 'Ilkhane of Persia'; but there are other Western statements to the effect that when, after the reigns of Abaca (1265-1282), Nikudar Achmed (1282-1284), and Argun (1284-1291), that ruling family became incapable, it was 'replaced in 1335 by the Ilkhanians'; here, manifestly, the term is used to denote nomad fragments of what from 1265 to 1335 was a nomad whole.

Ilkley, a watering-place in the West Riding of Yorkshire, on the Wharfe, among heathery hills, 13 miles NNW. of Bradford and 16 NW. of Leeds. Since 1846 it has become the seat of several hydro-pathic establishments. It occupies the site of a Roman station, and in the churchyard are three curious Saxon crosses; whilst Bolton Abbey (q.v.) is 5 miles north-west. Pop. 9000.

Il, a river of Alsace, rising to the south-west of Basel, and flowing 127 miles north-north-eastward, till it falls into the Rhine 9 miles below Strasburg. It is navigable over nearly one-half of its course.

Ille-et-Vilaine, a maritime French department, formed out of the north-eastern portion of Brittany. Area, 2596 sq. m.; pop. (1872) 589,532; (1901) 611,477; (1921) 558,574, mostly of Breton origin. It is watered chiefly by the Vilaine and its tributary the Ille, which unite near Rennes, the capital of the department. Ille-et-Vilaine consists of a granite plateau traversed by ranges of low hills. It is agricultural. Its cider is the best in France; the butter of Rennes is celebrated; the horses of the department are noted for their endurance, and are in great request for the army; and bee-keeping

is prosecuted. Iron is mined; slates are quarried; and salt is extracted. The department is divided into six arrondissements—Rennes, Fougères, Montfort, St Malo, Vitré, and Redon. St Malo is the principal seaport.

Illegitimacy forms one of the most difficult of social problems; and there is no branch of social science in which there is such deficiency of literature. And yet its importance is sufficiently evidenced by the fact that in 1923 30,959 illegitimate children were born in England and Wales, and 7477 in Scotland. In that year the illegitimate births registered in England amounted to an aggregate of about 4.1 per cent. of the total births. It is noticeable that, while the marriage-rate, and consequently the legitimate birth-rate, has declined on the whole for some years, the illegitimate birth-rate has also fairly steadily declined. From 1841 to 1859 the proportion of illegitimate births to the total number registered ranged from 6.3 to 7 per cent.; in the ten years from 1878 to 1887 the average was 4.8 per cent. The decline continued into the early years of the 20th century, and is very striking, because in 1841-59 the rate fluctuated between 6 and 7 per cent. with a remarkable uniformity. In the year 1845, 70 out of every 1000 births registered in England and Wales were illegitimate; in 1902 only 39 out of every 1000; in 1914-18 about 50; in 1920-23 about 44. Generally speaking, and spite of fluctuations, the highest rates of illegitimacy are recorded in the least densely populated districts. Unfortunately it is not possible to draw from this fact any conclusion referring to the education or prudential habits of the people, for in Scotland, where education is general and thrift national, the rate of illegitimacy is notoriously high. And, for morals, it should be remembered that a high percentage of illegitimacy may mean that there is no prostitution.

In Scotland the rate increased from 7.88 in 1855 to 10.27 in 1866, but this may have been due to more perfect registration at the latter date. From 1866 there was a steady diminution; in 1874 the rate fell below 9 per cent., in 1890 to below 8 per cent., in 1898 to below 7 per cent., and in 1903 to 6.13. Then came fluctuations. In 1914-18, 7.3 per cent. were illegitimate; in 1920-23, 7.05 per cent. Not only the rate but the actual number of illegitimate births decreased until 1903, notwithstanding the steady increase in the population: in 1866 they numbered 11,673; since 1877 they have been fewer than 11,000; from 1888, fewer than 10,000; and in 1898-1903 fewer than 9000. The tendency to illegitimacy in Scotland is greater in the north-eastern and southern rural districts than in the south-western mining and manufacturing districts—which is much the same distinction as is observed in England. Only, in no part of England are the figures so unfortunately high as in Scotland. Various theories have been advanced to account for this, but it is doubtful if the whole solution has yet been found. The following may at any rate be instanced as among the probable causes of the prevalence of illegitimacy in Scotland: a national caution, which deters from early and improvident marriages; the laxity of the marriage-laws in respect of the subsequent legitimation of children born out of wedlock; and the herding together of farm-labourers in bothies and farm-buildings. It is to be noted, also, that a large proportion of the illegitimacy can hardly be ascribed to vice, seeing that the parents often live together and rear their families just as if they were legally married, as, perhaps, many of them will ultimately be. For this curious practice no doubt the former high proclamation fees may have been to some extent responsible.

In Ireland a very different state of affairs obtains. There, in 1903, of 101,831 births registered only 2603 or 2·6 per cent. were illegitimate. From 1884 the percentage long ranged between 2·9 and 2·6. In 1918-21 it was 3·2. It is much lower in Connaught than in Ulster. The sharpness of this contrast in favour of Ireland has frequently been set to the credit of the Roman Catholic Church and the influence of its priests. Mr George Moore has even lamented that 'the strange and awful chastity' of the Irish people has killed all joy amongst them; others have hinted that it is associated with the increase of lunacy, and that 'a hundred bastards would be a more gracious sign than one lunatic.'

Statistics do not, however, enable one to form any conclusion as to the causes of illegitimacy in respect of race, of religion, of education, of industrial occupation, or of distribution of population. Sweden is much worse than Norway, Bavaria much worse than Prussia, Belgium much worse than Holland. It is a remarkable fact that in the year 1851 more than one-half of the entire births in Vienna were illegitimate, but there is no explanation forthcoming of that fact, nor of the improvement generally observable. In Europe generally, although not universally, there seems a tendency to decrease in the rate of illegitimacy; but how far that appearance may be due to moral causes, how far merely to more comprehensive statistics, it is impossible to say.

See the periodical reports of the registrars-general for England, Scotland, and Ireland; the official year books of the Dominions; also A. Leffingwell's *Illegitimacy and the Influence of the Seasons on Conduct* (1892). For the legal position of the illegitimately born see BASTARD.

Illicium, or STAR-ANISE. See ANISE.

Ilimani, one of the principal mountains of the Bolivian Andes, 40 miles S.E. of La Paz. Height, 21,000 feet. See ANDES.

Illinois, popularly known as the 'Prairie State,' is the twenty-third in area of the United States, but the third in population, and extends from Wisconsin and Lake Michigan on the N. and N.E. to the junction of the Ohio and Mississippi rivers at the extreme S.W.—a distance of nearly 400 miles. It is bounded on the E. by the state of Indiana, from which it is partly separated by the Wabash River; on the S. it is separated from Kentucky by the Ohio; and on the W. the Mississippi flows between it and the states of Iowa and Missouri. The area is 56,650 sq. m., or nearly that of England and Wales.

The surface of Illinois is the most level of any state in the Union, except Delaware and Louisiana; and its wide grassy plains, though broken by numerous streams fringed with belts of fine timber, have gained for it the name of the Prairie State. The drainage is towards the south-west, through streams which flow into the Mississippi. The Illinois River, the largest in the state to which it gives name, is formed by the union of two streams in the north-east of the state, about 45 miles south-west of Lake Michigan, and has a south-west course of about 500 miles in all, joining the Mississippi 20 miles above the mouth of the Missouri. The fertile soil—a heavy black loam—with a favourable climate, makes this the richest agricultural state in the Union; and Illinois ranks among the first for the production of corn, oats, cattle, hogs, horses, and poultry.

The principal crops are maize, oats, hay, wheat, potatoes, rye, barley, sweet-potatoes. Much fruit is raised, especially for the markets of Chicago. Forests still cover about one-tenth of the land. Honey and wax are obtained on a large scale. There are over 1,000,000 horses, 2,700,000 cattle,

4,700,000 swine, and 500,000 sheep in the state.

The mineral output of Illinois, especially of bituminous coal, is also very large; it ranks among the first in this respect. Nearly a fifth of the entire coalfield of the United States is found within its bounds; and though some three-fourths of the coal is found in the Joliet region in the north-east, collieries extend over the greater part of the state. Iron, lead, and zinc are also worked; and other minerals are copper, silver, asphalt, tripoli, gypsum, marble, limestone, salt, and fluor-spar, the last found near Roseclare. In petroleum the state ranks among the highest. There is natural gas; and there are brine springs in the south.

The position of Illinois presents unusual facilities for commerce. It has 400 miles of navigable rivers; a waterway to the Atlantic through the great lakes; and the drainage-canal from the Chicago River to the Desplaines will connect Chicago with the Mississippi River. Illinois has more railroad mileage than any other state, except Texas (16,000 miles). The trade of the state centres in Chicago, and in the article on that city some indication of the leading manufactures will be found. These are of wide range, those connected with iron and steel and with agriculture being specially important.

The state is divided into 102 counties. The governor and most of the other state officers are elected for four years, the judges of the supreme court for nine. The legislature meets biennially; and to the lower house each district returns three members, cumulative voting being permitted in order to provide for the representation of minorities. Twenty-seven representatives are sent to the Federal congress. The provisions for education are liberal. The state maintains two normal schools, an agricultural college, and an industrial university; and besides these there are many other colleges and universities. A compulsory educational law is in force, which requires children between the ages of seven and fourteen to attend for at least sixteen weeks in the year some public day school, or some private school teaching the branches commonly taught in the public schools. The most important educational institutions, including the magnificently endowed Chicago University, are in and about Chicago (q.v.). Elsewhere are the state university of Illinois (Urbana), North-western University (Evanston), the Wesleyan University (Bloomington), James Milliken University (Decatur), and several other colleges and state normal schools. The state institutions include hospitals for the insane, at Elgin, Jacksonville, Anna, Chicago, &c.; an institution for the deaf and dumb, and another for the blind, at Jacksonville; an asylum for the feeble-minded at Lincoln; a home for the orphans of soldiers at Normal; an eye and ear infirmary at Chicago; a reformatory at Pontiac; and a soldiers' and sailors' home at Quincy.

Formerly a part of the North-west Territory, Illinois was organised as a territory in 1809, and admitted as a state on 3d December 1818. While the Federal law at that date made a population of 40,000 a condition of admission, it is well established that the actual population of Illinois was then but 34,620. In 1830 the population numbered 157,445; in 1850, 851,470; in 1870, 2,539,891; in 1890, 3,826,351; in 1910, 5,638,591; and in 1920, 6,485,280. Chicago is the largest city of Illinois; its limits embrace more than two-fifths of the entire population of the state. Peoria, East St Louis, Rockford, and Springfield (the capital) rank next in population. Important events in the history of Illinois have been the Indian wars of the territorial period, the Black Hawk war of 1832, and the Mormon (q.v.) troubles in 1840-44. The state raised six regiments for the Mexican war, and

during the civil war contributed 259,092 men to the Union armies, of whom over 29,000 were killed in action or died of wounds or disease. At Springfield Abraham Lincoln lived before he was elected president, and there he is buried.

Illipe, or **ILLUPI**, a name applied to various species of *Bassia* yielding nuts and oil (see **BUTTER-TREE**); less properly to Borneo Tallow (see **DIP-TEROCARPACEÆ**).

Illiterates, a term used to designate those persons who are unable to read or write, or both. The percentage of illiterates in a country furnishes one of the few means of estimating quantitatively the average level of intelligence, or at least of education, possessed by the people of that country. Unfortunately a strict comparison cannot be made, because the statistics of illiteracy in different countries are not based upon one uniformly recognised method of obtaining them. (1) Some countries endeavour to take an exact census of illiterates; in their enumerations all children below ten years (or some other age) are excluded.

United States (1920) 6.0 p.c.	France (1906).....14.1 p.c.
Italy (1911).....37.0 „	Portugal (1911).....68.9 „

The percentage of the United States was 22.15 in 1880, and in 1890 it had fallen to 13.3. In 1920 it was 2 per cent. for native whites, 13.1 for foreign whites, 22.9 for coloured people. (2) The percentage of persons signing marriage registers by mark may be recorded. On this basis we have the following results. In England and Wales, in 1863, 23.8 per cent. men and 33.1 per cent. women signed their marriage register by mark; in 1900 the figures were only 2.8 per cent. men and 3.2 per cent. women; in 1914, 0.8 and 1.0. In Scotland in 1901 the proportion was 2.16 per cent. men and 2.76 per cent. women; in 1920, 0.4 for both. In Ireland in 1901 the proportions were 9.8 per cent. men and 7.1 per cent. women; in 1920, 3.0 and 2.1. (3) Statistics for army recruits lose much of their value with the disappearance of compulsory service.

Illkirch, or **ILLKIRCH-GRAFENSTADEN**, a manufacturing town in Lower Alsace, on the Ill; pop. 7000.

Illo (or **ILOW**), **CHRISTIAN**, Austrian general in the Thirty Years' War, and intimate friend of Wallenstein (q.v.), married a Bohemian heiress, and was ennobled. He helped to force on Wallenstein's quarrel with the Emperor, and he was murdered in 1634 at Eger by Butler, Gordon, and Leslie.

Illorin. See **ILORI**.

Illyd, or **ILFUTUS**, a Welsh saint born in Brittany, was a grand-nephew of St Germanus of Auxerre, and flourished in the first quarter of the 6th century. He was at the court of King Arthur as courtier, but, ordained by the Bishop of Llandaff, built a church and monastery at Llantwit-Major in Glamorganshire.

Illuminants. See **ACETYLENE**, **CANDLE**, **ELECTRIC LIGHT**, **FAT**, **FUEL**, **GAS**, **LAMPS**, **LIGHTHOUSE**, **LUCIGEN**, **OILS**, **PARAFFIN**, **PETROLEUM**, **PHOTOMETRY**, **STEARIN**.

Illuminati (Lat., 'the enlightened'), a name assumed by or conferred upon various mystics professing to have special knowledge of God and things divine. The sects which may be included under the title are the *Alombrados*, who originated in Spain about 1520, and were finally crushed by the Inquisition; the *Guérinets* in France, who flourished from 1623 to 1635; another sect which arose in the south of France about 1722, and perished in the storms of the Revolution; an association of mystics in Belgium, in the later half of the 18th century. But the name is more particularly given to the Order of the *Illuminati*, founded at

Ingolstadt on May 1, 1776, which soon spread over almost all the Catholic parts of Germany. Its founder, Adam Weishaupt (1748-1830), professor of Canon Law at Ingolstadt, at first called it the Order of the Perfectibilists. Filled with detestation of Jesuitism, and impatient of the restraints which were at that time imposed on the freedom of human thought in Catholic Germany, especially in Bavaria, Weishaupt set himself to combat ignorance, superstition, and tyranny, by founding an association which should be a luminous centre for the promotion of rational and religious enlightenment. Religious dogmas and forms of worship were rejected; his religious system was a form of deism. But the society prosecuted political aims as well, in that the members of the highest of the orders into which it was divided were pledged to the furtherance of Republican opinions. Implicit obedience to the chiefs of the association was one of the first laws of its constitution. The accession of Baron von Knigge to the new order, and the support which it received from the Freemasons, led to its rapid extension; about 1780 it counted more than 2000 adherents, mostly men of rank and influence. It was regarded with favour by Goethe, Herder, Nicolai, Ernest II. of Gotha, and Karl August of Weimar. Weishaupt and Knigge quarrelled in 1784. The order began to be openly denounced as dangerous, in 1784 and 1785 edicts were issued by the Elector of Bavaria for its suppression, and Weishaupt was degraded and banished. See two works published by him in 1787, and an article on illuminism in the *Edinburgh Review* for July 1906. —*Illuminism*, the system of the French illuminati, is sometimes used as a synonym for Freemasonry and unbelief, from a Catholic point of view.

Illumination of Manuscripts, the art of painting manuscripts with miniatures and ornaments, an art of the most remote antiquity. The Egyptian papyri containing portions of the Ritual or 'Book of the Dead' are ornamented with veritable drawings and coloured pictures. Except these papyri, no other manuscripts of antiquity were, strictly speaking, illuminated; such Greek and Roman manuscripts of the 1st century as have reached the present day being written only. Pliny, indeed, mentions from Varro that authors had their portraits painted on their works, and refers to a biographical work, with numerous portraits introduced, but all such have disappeared in the wreck of ages; the oldest illuminated MSS. which have survived being the *Dioscorides* of Vienna and the *Virgil* of the Vatican, both of the 4th century, and ornamented with vignettes or pictures in the Byzantine style of art. St Jerome, indeed, in the same century, complains of the abuse of the practice, as shown by filling up books with capital letters of preposterous size. The Byzantine style strongly influenced every other early style throughout the West, and its influence can be traced as late as the 11th century.

The art of illuminating manuscripts with gold and silver letters is supposed to have been derived from Egypt, but it is remarkable that no papyrus has any gold or silver introduced into it. The artists who painted in gold, called *Chrysographi*, are mentioned as early as the 2d century. One of the oldest manuscripts of this style is the *Codex Argenteus* of Ultras (360 A.D.); and the charter of foundation of Newminster at Winchester by King Edgar (966 A.D.), six centuries later, shows the use of these letters. Gold letters seem to have been used in the East during the 12th and 13th centuries. At an early period the use of illuminated or decorated initial letters commenced—to be distinguished from the illuminated or painted

pages placed at the head of Byzantine manuscripts. Originally they were not larger than the text, or more coloured; but the Syriac manuscripts of the 7th century have them with a pattern or border; and they go on increasing in size and splendour from the 8th to the 11th century, when large initial letters, sometimes decorated with little pictures or miniatures, came into fashion in the Greek and Latin manuscripts. The subjects of the figures mixed up with the arabesque ornaments often referred to the texts; warriors and warlike groups of figures being introduced when the text referred to war, symbolical representations of hell where the chapters following treated on that region. These initial letters soon increased to a great size, being from 2 to 24 inches long; they were most used in the 8th and 9th centuries, but continued till the 12th century, and degenerated in the 16th to the last decadence of art—the grotesque. In the 13th century burnished gold was used as a background for letters and miniatures, and so finely were these backgrounds executed that they appear like plates of solid gold. The art which flourished in the eastern and western empires passed over to Ireland, and there gave rise to a separate school or kind of illumination. This style, which consists in a regular series of interlaced ribbon ornaments, often terminating in the heads of gryphons and other animals, seems to have been derived from the later patterns of Byzantine art, seen on mosaics, mural paintings, and other objects. This Celtic style is finely exhibited in the remarkable MS. at Trinity College, Dublin, known as the ‘Book of Kells,’ which is believed to be of the 9th century. The minute size and number of the interlacements is quite wonderful.

The Hiberno-Saxon style is seen in the so-called Durham Book in the British Museum (Cott. MS. Nero D. IV.), which is only second to the Book of Kells in beauty. It was written by Eadfrith, Bishop of Lindisfarne (died 721), in honour of St Cuthbert. The various schools of art in the middle ages found their homes in the different monasteries, and the so-called *Opus Anglicum* is exhibited in the Benedictine now in the possession of the Duke of Devonshire at Chatsworth. This was produced at the Old Minster at Winchester, and was executed by Godemann (afterwards abbot of Thorney) for Ethelwold, Bishop of Winchester (963–984).

In the 12th century a new style arose which was distinguished by the profusion of its ornamentation, intricate modes of illumination, and abundant use of gold and silver. In the 13th century the art still more deteriorated in western Europe, but the manuscripts of the 14th century show a great advance in painting over the works of previous centuries. Dante’s *Divina Commedia* in the British Museum (Egerton MS. 943) is a fine specimen of the work of Italian artists in this century. The Arundel Psalter, also in the British Museum (Arundel MS. 83), is a noble work of English artists. It was given by Robert de Lyle to his daughter Audry in 1339.

In the 15th century the art of miniature began to decline in England, and the finest works were produced by foreign painters. This is the case with the famous Bedford Missal in the British Museum. It was prepared for John, Duke of Bedford, son of Henry IV. and Regent of France, on his marriage in 1423 with the daughter of John, Duke of Burgundy. The duchess presented the MS. (with her husband’s consent) to Henry VI. on Christmas Eve, 1430. In this same century were produced the celebrated choir books in the cathedral of Siena, by Girolamo da Cremona and Liberale da Verona, who were paid for their work

in 1468 and 1472–73. One of the most beautiful specimens of the work of the next century is the Book of Hours of Anne of Brittany, wife of Louis XII., which has borders of natural plants on a gold ground. The artist to whom we are indebted for this priceless monument of French art at the period of the Renaissance was Jean Bourdichon (1457–1521).

The usual mode of production adopted in the Scriptorium was for the scribe to rule a space for his text in accordance with the general design, and to write within these limits. He was followed by the illuminator of initials, borders, and ornamental accessories. Then came the miniaturist. St David, the patron saint of Wales, is said to have been an assiduous illuminator, and among the most celebrated miniaturists may be mentioned Giotto (1276–1337), Fra Angelico (1389–1455), Attavante (1455–1520), Julio Clovio (1498–1578), Vincenzo Raimondo (died 1557), and Boccardino (16th century). Raphael and Jan van Eyck might be added to the list. That splendid example of Flemish illumination, the Franciscan Breviary of Cardinal Domenico Grimani (1461–1523), has been attributed to Memling, but later inquiries have proved that he had nothing to do with it.

In the reign of Louis XIV. the art became extinct, ending with a style of painting called *camaïeu gris*, a kind of monochrome, in which the lights are white or gold, and shaded so as to emulate bas-reliefs. Among oriental nations the Persians, Hindus, and Chinese have illuminated manuscripts of great beauty, none of which, however, can compete with those of the western nations in antiquity. For beauty of design some of the Arab manuscripts are charming, but their antiquity does not reach beyond the 13th century. The Chinese Buddhists have also illuminated classics, or religious books of their sect, one of which, the *Diamond Book*, as it is called, in the British Museum, has a text splendidly printed in silver and gold letters on a blue ground, and the vignettes charmingly painted in tempera, on macerated leaves of the *Ficus Indica*.

Bradley, *Manual of Illumination* (1861); *Dictionary of Miniaturists* (3 vols. 1887–89); books by Tymms and Digby Wyatt (1860), Audsley (1861), and Shaw (1866); Birch and Jenner, *Early Drawings and Illuminations* (1879); Middleton, *Illuminated Manuscripts* (1892); Warner, *Illuminated MSS. in the British Museum* (1903); Madan, *Books in Manuscript* (1920).

Illuminations. See PYROTECHNY.

Illuminism. See ILLUMINATI.

Illupi. See ILLIPE.

Illusions are usually distinguished, as having some basis in outward physical facts, from *delusions*, which are purely subjective hallucinations, with no foundation save perverted imagination, or otherwise disordered faculties. See OPTICAL ILLUSION, APPARITIONS, DREAMS, HALLUCINATIONS, INSANITY.

Illustration of Books. Since man first discovered how to convey his thoughts to others by means of writing, he seems to have felt the want of some method of illustration or embellishment. From the Egyptian papyrus down to the invention of printing this was supplied by pictures, coloured or uncoloured, engravings, carvings, &c., executed by hand, and so far as these have any connection with books or writings their history will be found in the article ILLUMINATION OF MANUSCRIPTS. The first printed books were entirely illustrations, both pictures and text being printed from blocks engraved on wood in relief, such as the *Biblia Pauperum* (q.v.), and many others. The *Ars Memorandi* (end of 15th century) comprised fifteen New Testament pictures, faced by the same

number of text pages, all engraved on wood. The *Mazarin Bible* (1455), the first book completely printed from movable types, many of the copies of which were beautifully embellished by hand, was sold as a manuscript, till the number of copies aroused suspicion. Many other spurious MSS. were produced in the same way, the larger price obtained for them forming a temptation to those having the secret of printing.

The first edition of the *Speculum Humanae Salvationis*, said to have been printed by Coster about 1440, is supposed to be the first book in which two different coloured inks were used on the same page; and the ornamental capitals in the *Psalter* of Fust and Schöffer in 1457 are beautiful specimens of printing in two colours. Probably the first printed book with wood-engraved illustrations used throughout the text was the *Fables* of Ulrich Bohner, issued by Albert Pfister, printer of Bamberg, in 1461, which had 101 engravings on wood. In Italy the first known example is the *Meditationes*, published by Ulrich Hahn, a German, in Rome, 1467, of which three copies are still known to exist. The most artistic book of this period was certainly a volume on military art by Valturius, illustrated by eighty-two designs by Matteo Pasti, at Verona, in 1472. The designs are in outline and very cleverly drawn, though poorly engraved.

The invention of the method of printing from engraved (intaglio) plates introduced a new factor into book illustration. *Il Monte Santo di Dio* (Florence, 1477) was the first book issued with illustrations engraved on metal.

In the beginning of the 16th century many books were beautifully illustrated by pictures in chiaroscuro, produced by three or four blocks, engraved on wood, printing different shades of the same colour, generally ochre, brown, gray, or red, many of the original drawings being by Titian, Raphael, Parmigiano, and other masters. About the middle of the 16th century engraved plates began to be used in conjunction with wood-engravings in the same books; and from this period a struggle for supremacy began between the two arts, which finally resulted in favour of metal at the end of the century. Wood-engraving declined till revived by Bewick, and metal-engraving and etching had the field to themselves. During the 18th century many books were beautifully illustrated by engraved and etched title-pages, vignettes, and tailpieces, the most celebrated artists making designs for the purpose; the type was first printed, leaving spaces on which the plates were afterwards printed. The lead taken by France in the 18th century was closely followed by Germany and England. Coloured illustrations, when not coloured by hand, as they generally were, were printed by means of numerous carefully prepared wood blocks, each printing a different colour. An elaborate account of the method will be found in Savage's work. In short, the history of book illustration reflects more or less faithfully the state of art of the period, and it may be traced in the articles Book, Engraving, Wood-engraving, Bartolozzi, Bewick, Caxton, Dürer, Hogarth, Turner, &c.

The invention of lithography in 1796 introduced a third element, which was immediately taken advantage of. Being much cheaper than steel-engraving, it gradually tended to supersede that process for book purposes, its special adaptability for coloured work giving it great advantages over its rival. In England book illustration may be said to have reached its culminating point as regards engraved and etched plates in the first half of the 19th century, in the series of annuals, keepsakes, and the higher-class books illustrated by such masters as Stothard, Turner, &c. The re-

vival of wood-engraving by Bewick and his pupils gradually led to the restoration of that art as an illustrating medium. In this it was greatly aided by the facility with which wood-engravings can be printed along with the text, together with the advance made in typographic printing. The series of Christmas books illustrated by John (afterwards Sir John) Gilbert and Birket Foster had no small share in that advancement. Among the artists who have helped to raise the art to its present high position may be mentioned Cruikshank, H. K. Browne (Phiz), Doyle, Leech, Tenniel, Millais, F. Walker, W. J. Linton, Herkomer, &c. The development of what has been called the American school of wood-engraving has still further increased the influence of that branch of art for illustrative purposes.

From this historical summary it will be seen that three methods of producing illustrations were employed—relief blocks, as wood-engravings; intaglio plates, as steel-engravings and etchings; surface-printing methods, as lithography. Modern books are still illustrated by these three methods, but the application of photography has quite revolutionised the actual processes used. Wood-engravings are no longer used except for rough catalogue illustrations and other special purposes; but the modern line and half-tone processes attain the same result by photographic and chemical means, and the vast majority of illustrations are produced by these modern relief methods. Steel-engraving is extinct, but the intaglio principle is still employed in Photogravure (q.v.), and the invention of a fast rotary method of printing the plates opens up great possibilities for this process in the future. Lithography, in its many applications and modifications, still holds its own, though it is not used extensively in book-illustration. The rotary method of printing has been applied to lithography also, and may enable this process to occupy some of the ground which relief processes have long considered their own.

Relief-block processes for book-illustration have the great advantage over the other two methods in that they may be printed in the same press and at the same time as type. The lines or parts which impress the paper are left in relief, while the white parts are cut or etched away so as to leave the paper unprinted. What are called process-blocks are divided into two kinds. The blocks made from pen-and-ink drawings or similar originals are known as 'line blocks' or 'zincos' (a contraction of the old name zincographs), while those made from wash-drawings, photographs, or other originals with a more or less full scale of tones are called 'half-tone blocks.' The original for a line block should consist of clean black lines or dots on a smooth white card, such as good bristol-board. Care must be taken to make the fine lines black, and not gray or broken. The drawing may with advantage be made slightly larger than the size of block desired, as the reduction gives a more finished and delicate result. The original is pinned in front of the camera, and a negative is made and finished off by intensification, so that the black lines of the original are represented by clear lines and the white paper by complete opacity. The camera used is of the copying type, strongly built, and running on rails, at the end of which is fixed the copyboard. The rails and copyboard are hung from springs to avoid vibration. A negative made in the ordinary way, viewed from the film side, is reversed as regards right and left; but, as it is placed film down in making a print, the resulting print is the same as the copy. In making a printing block there is an extra process, as the negative is printed on to the metal plate, and from the metal plate on to the paper. This necessitates a 'reversed'

negative, and this is made either by lifting the film off the glass after the negative is finished, turning it over, and laying it on the glass again; or making the negative with a plane mirror, silvered on the surface, mounted at the back of the lens at an angle of 45° , or a right-angled prism mounted in front of the lens. When a mirror or prism is used the camera has to be turned 90° —i.e. till parallel with the copyboard.

The wet collodion process is still in general use for both line and half-tone work, though gelatine dry-plates made for this class of work are quite satisfactory. The speed of working is about equal, for, though the wet-plate requires longer exposure, the subsequent operations and the drying are much faster. As the glasses are used over and over again with wet-plate a better quality of glass can be used, and also with wet-plate the films of several negatives can be 'stripped,' placed on one piece of glass, and carried through as one. A piece of zinc plate is polished and coated thinly and evenly with a solution of bichromated albumen, dried, placed in contact with the negative, and exposed to light. The plate is next rolled up lightly with a greasy ink and placed in water. The water penetrates the ink and dissolves the parts of the film which have been protected by the opaque portions of the negative, and the ink comes away from these parts on wiping gently with cotton-wool. This ink image is strengthened by dusting with powdered bitumen and heating the plate. The back of the plate is protected with acid-proof varnish, and the plate given a short etch in weak nitric acid. The unprotected parts are etched away, leaving the lines slightly in relief; but as the continued action of the acid would undermine the lines, and finally eat them off altogether, some means have to be taken to protect the sides. One method is to heat the plate and cause the ink to run down the sides, and after each etch to roll on more ink, dust with powdered resin, and heat the plate. Another and more modern method is to brush a powdered red resin, known as 'Dragon's Blood' (q.v.), across the plate in such a way as to pack it against the sides of the lines, while leaving the bottom bare. The plate is heated to fix the resin, and then cooled and brushed across from the opposite side, heated, and so on till all four sides have been protected, and the plate is given another etch. When the plate is deep enough the resist is washed off. The sides of the lines are seen to be in the form of a series of steps, each step representing an etch. There is a risk of these steps or 'shoulders' printing up, especially if printed on soft paper, so they must be removed. This is done by rolling the plate with stiff ink and a hard roller, the effect being to protect only the top and the sides down to the mark of the first etch. The plate is then etched in a weak bath, which acts mostly on the projecting edges of the steps, and leaves the lines with smooth, gently sloping sides. The large open spaces are cut deeper in a machine known as a 'router.' The plate is then mounted on a piece of hard wood so that the thickness is equal to 'type-height,' and the block is ready for the printer.

The half-tone process is the same in principle, but in addition the various tones of the photograph or wash-drawing have to be translated into a grain or stipple which varies from a very fine black dot in the whites to an almost unbroken surface of black in the shadows. The process employed was patented by Meisenbach of Munich in 1882 in a rather primitive form. The camera used in making the negative is constructed with an adjustable frame to hold a cross-line screen immediately in front of the sensitive plate. The cross-line screen consists of two plates of glass, each engraved with

a series of fine parallel lines filled in with black pigment, and cemented face to face so that the lines cross at right angles. The shape and size of the stops used in the lens, the exposure, and the distance between the screen and the sensitive plate are the chief factors which govern the result, and when these are correctly adjusted a negative is obtained in which the image consists of dots, each dot corresponding to one of the spaces formed by the intersection of the lines of the screen, but varying in size according to the amount of light reflected by the original at that part. The finished negative shows, under a lens, a picture made up of dots of varying size but of equal opacity, with the spaces between them perfectly transparent. The negative is printed on to the metal plate, copper being generally used, except for coarse work, when zinc is used. The copper plate is coated with bichromated fish-glue, exposed under the negative, and washed thoroughly to remove the unaltered glue. As the glue image is transparent it is stained with aniline dye, and if found satisfactory, the plate is heated strongly and the glue bakes into a hard glassy enamel. The etching-fluid used for copper is perchloride of iron, and as the spaces between the dots are very small, precautions against undercutting are not necessary, and the dots are left large enough in making the negative to allow for the lateral action of the etching-fluid. Some local etching is generally necessary to give sparkle and contrast. The plate is trimmed and mounted on wood to type-height. Half-tone blocks require much more care in printing than line blocks, and the fineness of the screen lines must be suited to the quality of the paper and ink used. The rulings in general use vary from 50 to 200 lines per lineal inch, the coarsest being used for fast-printed daily newspapers, and the finest for scientific or other illustrations which must reproduce as much minute detail as possible. The ordinary book-illustrations are done in 150 lines per inch.

Drawings for half-tone process should be made in pure black or sepia if possible; but if a white must be used, one of the special 'process white' colours is to be preferred to ordinary Chinese white, which photographs darker in tone than it appears to the eye, and so alters the effect of the drawing.

The three-colour process is an application of the half-tone process, based on the Young-Helmholtz theory of colour-vision, suggested by Clerk Maxwell in 1861, and made a practical, commercial process by the work of Vogel, Abney, Ives, and many others (see PHOTOGRAPHY). Three negatives are made from the coloured original, through colour-screens or light-filters placed in front of the lens. These filters are coloured red, green, and blue-violet, and the negatives made through them record the amounts of blue, pink, and yellow reflected by the picture. Half-tone blocks are made of these negatives, and printed in exact register, superimposed, and in the inks corresponding to the colour recorded in the respective negatives. The yellow is generally printed first, and the blue last. Owing to the imperfect colour-sensitiveness of the plates and faulty inks, as well as the natural limitations of the process, a very considerable amount of handwork is necessary, in etching the blocks, in order to obtain a facsimile of the colours of the original; but if too much is not asked of the process some wonderfully faithful and beautiful results are possible. In the line and half-tone processes, the wet collodion process is generally employed in making the negatives; but in the three-colour process only highly colour-sensitised gelatine or collodion emulsion plates can be used (see PHOTOGRAPHY). In some cases an additional block is used to give tone and richness to the picture, more especially in the grays and dark colours. This extra block is made from an ortho-

chromatic negative (see PHOTOGRAPHY), and adjusted in etching to give the desired result when printed in gray or black ink. The order of printing when four blocks are employed is frequently varied to suit the subject; but the usual sequence is yellow, red, black, blue. The four-colour process has no exact theoretical basis like the three-colour, and depends entirely on the skill of the etcher to produce the desired result, but when the blocks are properly adjusted the result is more pleasing. The black printing has a steadying effect on the very delicate balance required to make grays and certain other tints when three colours only are used.

Originals for the Three-colour Process.—Almost any coloured drawing, as well as coloured objects of all kinds, can be reproduced by this process if sufficient handwork is spent on the blocks; but the subjects which are best adapted to the process are clean, bright water-colour drawings. The use of such colours as emerald-green, lilac, and pure ultramarine should be avoided, as the colours of the printing-inks are not pure enough for any combination of them to reproduce these colours exactly; but the colour of adjacent portions of the original has a great effect on the apparent purity and intensity of such colours.

For purely photographic methods of illustration, such as colotype, see PHOTOGRAPHY.

Illyria (Lat. *Illyricum*), in ancient times the country that stretched along the eastern side of the Adriatic Sea, from Epirus northwards. It was not a homogeneous territory, but varied in extent at different periods of its history. The region was inhabited by numerous tribes, who seem seldom to have been held together by any sort of political cohesion. Its meaning in modern times has consequently been somewhat vague, and its inland boundary ill-defined. From some cause or other—probably the mountainous character of the region they inhabited was the principal cause—the Illyrians were the last of the peoples of the Balkan peninsula to be brought within the fold of civilisation. The single Greek colony of Dyrrhachium or Epidamnus, in the south (now Durazzo), was the only point whence the rays of Greek enlightenment could penetrate the darkness of Illyrian barbarism. The Illyrians are described as resembling the savage Thracians in their manners, as tattooing their bodies, as offering human sacrifices to their deities, but as honouring women, who even held chieftainships amongst them. For many years they seem to have kept up a series of incessant attacks upon their neighbours to the east, the early kings of Macedonia; they levied tribute from Amyntas II., and slew Perdiccas (359 B.C.). But they were subdued by Philip II. and Alexander, who annexed their country to Macedonia. In the 3d century, after the breaking up of the Macedonian monarchy, they caused much annoyance to Greece and Italy by their piratical excursions. At length the patience of Rome was exhausted, and in two short wars (229 and 219 B.C.) she succeeded in subjugating the refractory Illyrians. Fifty years later they provoked a third war

with Rome, which resulted in their defeat and the incorporation of their territories in the all-victorious republic. Nevertheless, the Illyrians only consented to be civilised at the sword's point. They frequently rose in revolt against their conquerors; but in 35 B.C. Illyria was made a Roman province. During the empire they served faithfully in the Roman armies, and even gave half-a-dozen emperors to the state, as Claudius II., Aurelian, Diocletian, Probus. Under the rule of the emperors the political importance of Illyricum was greatly increased, as was the area to which the name was applied. In the 2d century Illyria extended as far north as the Danube, and even beyond it, and included Noricum, Pannonia, Moesia, Thrace, and Dacia. Constantine still further enlarged its boundaries, and made it one of the four chief divisions of his empire. But when the empire was divided between East and West, Illyria was also divided. Noricum, Pannonia, Moesia, &c. were designated as Illyris Barbara, and incorporated with the empire of the West; Illyris Graeca, embracing Greece, Macedonia, Epirus, &c., was attached to the eastern empire. In the period of the final dissolution of the western empire Illyria was successively overrun by the Goths, the Huns, and several Slavic tribes, and nearly all traces of civilisation disappeared. The Illyrians themselves partly amalgamated with the Huns and their Slavic conquerors, and partly were driven southwards, where one of their tribes, the Albani, survives, at all events in name, in the modern Albanians. As the several Slavic states became consolidated and rose to power, the political importance of Illyria, and even its name, gradually died away. The name was revived in quite modern times, when Napoleon, in 1809, formed the territories he had wrested from Austria into the Illyrian provinces. In 1816, when they were restored to Austria, that power constituted out of them and the provinces of Carinthia, Carniola, Görz, Gradisca, and Istria the kingdom of Illyria. But the designation was dropped in 1849, and the territories included in it were reorganised as provinces. King of Illyria, however, continued to the end to be one of the titles of the emperor of Austria.

The geographical features of Illyria are described under ALBANIA, BOSNIA AND HERZEGOVINA, DALMATIA, MONTENEGRO, &c., the modern states or provinces with which it most nearly coincided.

The name Illyrian is also used in other significations. In the 17th and 18th centuries it was used to indicate those Slavs who were members of the non-united Greek Church—i.e. principally the Serbians or Razans. The country is now mainly Southern Slav in population, the chief exception being Albania, which has perhaps historically the best right to the name. In the 19th century, therefore, the terms Illyria and Illyrian peoples were used in connection with the idea of the union of the Southern Slavs—the Serbians, Croats, and Slovenians—into a revived Illyrian kingdom, an idea which seems to have been first made current by Gaj about 1835. For this movement and its consummation, see CROATIA-SLAVONIA, YUGOSLAVIA. Portions of the former Austrian kingdom of Illyria which remain outside the Yugoslav state are most of Carinthia (which remains Austrian, a southern corner ceded to Italy), Görz or Gorizia, Gradisca and Istria (Italian). South Hungary became Yugoslav, but Fiume (q.v.), disputed by Italy, was left independent by the treaty of Rapallo (1920), which also assigned to Italy a few of the Dalmatian islands (Cherso, Lussin, Unie, Lagosta) and sovereignty over Zara. Fiume became Italian in 1924. By Illyrian language and literature is meant Serbian, including Croatian and Dalmatian. See SERBIA.

Ilmen, a lake in the Russian government of Novgorod, with an area of 350 sq. m., and discharging by the Volkhof into Lake Ladoga.

Ilmenau, a town of Thuringia, 30 miles S. of Erfurt, with great technical and other schools, manufactures of glass, porcelain, chemicals, toys, and gloves, but frequented as a health-resort; pop. 11,000.

Ilmenite (titanate of iron, FeTiO_3) occurs in black platy crystals belonging to the trigonal system. It has a hardness = 5-6 and density = 4.5-5. It is distinguished from hæmatite by its streak, which is nearly black, and from magnetite by its feeble magnetism.

Iloilo, a seaport of the Philippine Islands on the island of Panay. The natives (Bisayas) of the district, with some Chinese half-breeds and a few negritos in the hills, hardly recognised the Spanish authority, and offered a fierce resistance to the American annexation. Iloilo has a fine harbour, and is an important commercial centre, exporting sugar. Pop. 50,000.

Ilori, or **ILLORIN**, capital of a province in northern Nigeria, and a great commercial centre, stands, at an elevation of 1300 feet, about 160 miles NNE. of Lagos. The people, 70,000 in number, are mainly Yorubas, Haussas, and Fulahs. The religions are Mohammedanism and heathenism.

Isenburg, a tourist-resort on the river Ilse, where it issues from the Harz Mountains, has a castle, believed to have been founded by Henry I., and converted in the 11th century into a Benedictine monastery with a famous school. The river and the precipitous Isenstein are connected with the fairy-tale of the Princess Ilse. Pop. 3000.

Isley, **EAST**, or **MARKET ISLEY**, a market-town of Berkshire, situated amid bleak and dreary downs, 9 miles N. of Newbury and $6\frac{1}{2}$ S. of Didcot. Its sheep-markets count among the most important in the kingdom. Archbishop de Dominis was rector of West Isley, 2 miles north-west.

Image. See **LENSES**, **MIRROR**, **PSYCHOLOGY**.

Images. The earliest known instance of the practice of making images of any sort is to be found in the caves of the Upper Palæolithic Age (the Old Stone Age) in Europe in what is known as the Aurignacian stage of culture. These images are often feminine in type, some of them being slender, while others are grossly developed, especially in the region of the hips, and have therefore attracted much attention. According to Elliot Smith, these images are personifications of the supposed life-giving powers of the cowrie shell; while other students claim that they are representations of women of the same physical type as the Bushmen of South Africa, who formerly lived much farther north than they do at present, for these women have an abnormal development of fat on the buttocks when they are well fed, a feature which is termed *steatopygy*. The making of feminine figurines did not cease with the Stone Age, but was carried on in predynastic Egypt and in the earliest group of food-producing communities of which we have knowledge. These communities were scattered throughout Mesopotamia, Elam, the Caucasus, southern Russia, the Balkans, Greece, and a few other places. It is highly probable that these images represent the attempts of early men to incorporate the idea of the Great Mother, who was the predominating deity of this early civilisation, and persisted for many thousands of years in that rôle, even when male deities had been introduced.

In the great civilisations of antiquity, such as those of Egypt, Babylonia, and Crete, images were

made to represent gods, men, and animals. One of the earliest known stone images in Egypt is that of Min, discovered at Koptos by Sir Flinders Petrie. An ivory figure, doubtless representing a king, has also been discovered by Petrie in a royal tomb of early date at Abydos. In the fourth and succeeding dynasties the Egyptians, as the result of the invention of the practice of mummification, began to make portrait heads and then portrait statues of the mummified dead, and to put them in the part of the tomb which was above ground, or, in the case of the pyramid, in the temple attached to the tomb. The ritual attached to these statues, and to the mummy itself, is of surpassing importance to the student of religion (see A. Moret, *Le rituel du Culte divin journalier en Egypte*, Paris, 1902). It is the basis of practically all the mortuary and temple ritual throughout the world in all ages. These portrait statues were supposed to be the abode of the double (the *ka*) of the person whom they represented. It was believed that by means of this statue the dead could communicate with the living, partake of food, and so forth. For this purpose the statue had to be animated. This was done by means of a series of ritual performances, prominent among them being the burning of incense and lustrations with water, the original meaning of which was to restore to the dead the products that he had lost during putrefaction. The most important ceremony associated with the animation of portrait statues was that of The Opening of the Mouth, during which a priest touched, with a copper chisel, the mouth, eyes, ears, and nose of the figure. After that it was supposed to live and to communicate with the living. This ritual was adopted by the Heliopolitan priesthood, the originators of the sun-cult in Egypt. From the time of the fifth dynasty onwards (circa 2750 B.C.) the king of Egypt, as Son of the Sun, had to perform a daily ritual at daybreak in honour of his father, the sun-god. In this he went through the ceremony of animation of the statue of the sun-god in exactly the same manner as he carried out the ritual connected with his dead father. A similar ritual of the animation of statues was possessed by the Babylonians, who evidently derived it from the Egyptians. The story of Pygmalion and Galatea was doubtless derived from the same source, for the Phœnicians (Pygmalion was a Phœnician king) derived much of their culture from the Egyptians.

The making of images is widespread throughout the world. Representations of human figures are found carved on megalithic monuments in France and elsewhere in western Europe. The earliest of these are feminine. The inspiration to which these sculptures owe their existence doubtless came from the eastern Mediterranean. The Greeks, living as they did in an area where images had been made for centuries, began, after the 6th century B.C., to fashion images for themselves out of wood, marble, and metal, and thus led up to their wonderful sculpture. As the result of the conquest of India by Alexander the Great Greek art was introduced to that country. This ultimately caused the Buddhists in the north-western parts of India to make images of Buddha. When Buddhism spread to China and Japan it took with it the practice of making images, primarily of Buddha. The practice of carving stone images was unknown in Japan, and possibly also in China, before the arrival of Buddhism. In the Hindu period in India, which followed the disappearance of Buddhism throughout the greater part of India, much use was made, and still is made, of images by both of the great sectarian bodies, Vishnuite and Shaivite alike.

In the East Indian Archipelago, Oceania in general, and in America, as well as in parts of

Asia and Africa, the first civilisation that can be detected was characterised by the making of stone images, which are still to be found in certain places. Often the practice of making them has long since died out. These images are intimately linked up with the mythology and magic of the peoples of this vast region, for they are connected with stories of the creation of the first men and women out of stone images, as well as with the procreation of men. In magic, especially in Melanesia, they are believed to be possessed of a magical potency which will cure disease and otherwise help men. Many native peoples have acquired from this early civilisation the practice of making images, but they usually make them of wood. The most primitive peoples of all, the food-gathering tribes of southern India, Borneo, and elsewhere, do not make images, except when sometimes they have been influenced by peoples of higher culture.

Apart from the great civilisations of antiquity there is little evidence for the making of images, especially of stone or metal. The Hebrews after their arrival in Palestine adopted the practice from the peoples whom they found there. Little evidence exists concerning the practice of making images among the early Teutons, although the Goths had images in the 4th century A.D. The Celts do not seem to have made images. The Romans owed the custom to the Greeks and Etruscans.

Images of animals have played an important part in the religious systems of the Egyptians, Babylonians, and so forth. It is only necessary to mention the animals that so often were placed on either side of the doorway of a temple to protect it from evil influences.

Image-worship (Gr. *eikonolatris*), the use in public or private worship of graven or painted representations of sacred persons or things, and especially the exhibition of honour, reverence, or worship to or towards such representations. Neither in the New Testament nor in any genuine writings of the first age of Christianity can any trace be discovered of the use of statues or pictures in the worship of Christians, whether public or private. The earliest allusion to such representations is found in Tertullian, who appeals to the image of the Good Shepherd as engraved upon the chalices. A very curious pagan caricature of Christianity of the same age, discovered scratched upon the wall of a room in the palace of the Caesars in Rome (see GRAFFITI), which rudely represents a man standing in the attitude of prayer, with outstretched hand, before a grotesque caricature of the crucifixion, and which bears the title 'Alexamenus worships God,' has been alleged by Roman Catholics as an additional indication of at least a certain use of images among the Christians of the 2d century. The tombs of the Christians in the Roman catacombs, many of which are of a date anterior to Constantine, frequently have graven upon them representations of the Dove, of the Cross, of the symbolical Fish, of the Ship, of Adam and Eve, of Moses striking the rock, of Jonah, of Daniel in the lions' den, of the apostles Peter and Paul, and, above all, of the Good Shepherd; and those compartments of the catacombs which were used

as chapels are often profusely decorated with sacred representations, the age of which, however, it is not easy to determine with accuracy. It is admitted by Catholics, however, that, from the fear of perpetuating idolatrous notions, for the first three centuries the use of images was rare and exceptional; nor was it until after the establishment of Christianity under Constantine, and particularly after the condemnation of the Nestorian heresy in 430, that statues and pictures of our Lord, of the Virgin Mary, and the Saints, were commonly introduced in churches, especially in the East and in Italy. And yet even in the 5th century the practice had already reached a great height, as we learn from the church historian, Theodoret, for the East, and from Paulinus of Nola, for Italy; and in the 6th and 7th centuries many popular practices prevailed which called forth the condemnation of learned and pious bishops both in the East and in the West. It was usual not only to keep lights and burn incense before the images, to kiss them reverently, and to kneel down and pray before them, but some went so far as to make the images serve as godfathers and godmothers in baptism, and even to mingle the dust or the colouring matter scraped from the images with the eucharistic elements in the Holy Communion! This use of images by Christians was alleged as an obstacle to the conversion of the Jews, and as one of the causes of the progress of Mohammedanism in the East; and the excesses described above provoked the reaction of iconoclasm. In the second Council of Nice (787) the doctrine as to the worship of images was carefully laid down. A distinction was drawn between the supreme worship of adoration, which is called *latreia*, and the inferior worship of honour or reverence, called *douleia*. The second Council of Nice declared that the worship to be paid to images is not the supreme worship of *latreia*, but only the inferior worship of *douleia*; and also that it is not *absolute*, and is not rendered to the images themselves, but *relative*—i.e. only addressed through them, or by occasion of them, to the original which they represent. A strange error in the translation of the Greek acts of the Council of Nice, by which it appeared that the same adoration was decreed by that council to images 'which is rendered to the Holy Trinity itself,' led to a vehement agitation in France and Germany under Charlemagne, and to a condemnation by a synod at Frankfort of the doctrines of the Council of Nice. But an explanation of this error, and of the false translation on which it was based, was immediately afterwards given by the pope; and eventually the Nicene exposition of the doctrine was universally accepted in the Western as well as in the Eastern Church.

At the Reformation the reforming party generally rejected the use of images as an unscriptural novelty, and stigmatised the Catholic practice as superstitious and even idolatrous. The Zwinglian, and subsequently the Calvinistic churches entirely repudiated all use of images for the purposes of worship. Luther, on the contrary, while he condemned the Roman worship of images, regarded the simple use of them even in the church for the purpose of instruction and as incentives to faith and to devotion as one of those *adiaphora*, or *indifferent* things, which may be permitted, although not of necessary institution; hence, in the Lutheran churches of Germany and the northern kingdoms, pictures, crucifixes, and other religious symbols are still freely retained. In many of the parish churches of England these remained till long after the Reformation. Thus, we find that William Dowsing found ample employment during ten months of 1644 in destroying pictures and images in the churches of the single county of Suffolk, in

accordance with an ordinance of parliament. In the modern Anglican Church the practice is still a subject of controversy. In the Presbyterian Church and in all the other Protestant communions images are entirely unknown, although figures of patron saints and eminent churchmen have occasionally been set up, as in the restored St Giles' High Kirk in Edinburgh.

The Roman Catholic Church, through the decree of the Council of Trent, disclaims the imputation commonly made against Catholics of the idolatrous worship of images, 'as though a divinity dwelt in them, or as though we [Catholics] asked anything of them, or trusted in them, as the heathens did in their idols.' It renews the Nicene distinction between *absolute* and *relative* worship; the latter of which alone—'whereby we worship Christ and the saints, who are the prototypes of these images'—it sanctions or permits; and it contends for the great advantage, especially in the case of rude and unlearned people, to be drawn from the use of pictures and statues in the churches as 'memorials of the sufferings and of the mercy of our Lord, as instructive records of the virtues of the saints, and exhortations to the imitation of their example, and as incentives to the love of God and to the practice of piety' (Sess. xxv. *On the Invocation of Saints*). In many foreign churches, especially in Italy, in southern Germany, and in France, are to be found images which are popularly reputed as especially sacred, and to which, or to prayers offered before which, miraculous effects are ascribed. But instructed Catholics declare that the legends connected with such images form no part of Catholic belief. Most Catholic books of instruction contain cautions against attributing such effects to any special virtue of the images themselves, rather than to the special faith, trustfulness, and fervour which are stirred up by their presence, and by the recorded examples of the mercy of God with which they are associated. For the modern Greek usage, see *ICONOCLASTS*. For pagan usage, see *IMAGES*.

Imagination. See *PSYCHOLOGY*.

Imago. See *INSECT*.

Imâm, or **IMAUM**, the officer who in Mohammedan mosques recites the prayers and leads the devotions of the faithful. In Turkey the imâm also performs the ceremonies connected with circumcisions, marriages, and funerals. The prophet Mohammed and his immediate successors bore the title Imâm, because they used personally to conduct the devotions of their followers. Hence the title came to mean head of the faith, and as such was borne by the Sultan of Turkey. For 'the Hidden Imâm,' see *ANSARS*, *ISMAILIS*, *MAHDI*.

Imatra Falls. See *FINLAND*.

Imbecility. See *IDIOCY*.

Imbros, or **IMOROS**, a Turkish island of the Ægean Sea, about 14 miles N.E. of Lemnos and the same distance W. of the mouth of the Dardanelles, was assigned to Greece by the treaty of Sévres (1920), but restored to Turkey (demilitarised) by that of Lausanne (1923). Area, 98 sq. m. The inhabitants are mostly of Greek descent. The island is mountainous, its highest summit attaining 1959 feet above sea-level. Goats and bees are kept. The inhabitants cultivate the soil and carry on fishing. The chief village, Kastro, is situated on the north coast, and occupies the site of the ancient town of Imbros. It is the seat of a metropolitan of the Greek Church.

Imeritia, or **IMERETHIA**. See *GEORGIA*.

Imitatio Christi, a famous book highly prized by devout Christians of all confessions, and translated into more languages than any book

except the Bible. The question of its authorship has given rise to a great controversy. It was formerly attributed unhesitatingly to Thomas à Kempis, and the best authorities still regard it as his work. But it has been claimed for Chancellor Gerson (q.v.), for Gerson, abbot of Vercelli (an apparently hypothetical person), for Walter Hilton, a monk of Sheen in Surrey, for Bonaventura, Bernard of Clairvaux, and for many other writers, both famous and obscure. See *KEMPIS* (*THOMAS A.*).

Imitation, in the science of musical composition, is the repeating of the same passage, or the following of a passage with a similar one, in one or more of the other parts or voices, and it may be either strict or free. When the imitated passage is repeated note for note, and every interval is the same, it is called strict, and it may take place in the unison or octave, or in any other of the degrees of the scale, either above or below the original passage. Canon (q.v.) is strict imitation carried on to some length. The progression of a passage may also be imitated by an inversion, or by reversing the movement of the original; also by notes of a greater or of a lesser value (see *AUGMENTATION*).

Imitation. See *MIMICRY*.

Immaculate Conception. The Feast of the Immaculate Conception of the Blessed Virgin Mary is celebrated on the 8th of December in the Latin, and on the 9th in the Greek Church, in which latter church it is held under the name of 'The Conception of St Anne,' the mother of the Virgin Mary. The festival of the Conception itself is traceable in the Greek Church from the end of the 5th century, and in the Latin dates from the 7th; but a great controversy prevailed for a long time in the West as to whether and in what sense the conception of the Blessed Virgin Mary was to be held immaculate, and in what sense the Blessed Virgin herself was to be held conceived without sin. It was believed to be a consequence of the doctrine of the divine maternity, and a necessary part of the honour due to the Incarnation, that the Blessed Mother should be held to have been at all times free from the stain of sin. This might have been either by her having been, like the prophet Jeremiah (Jer. i. 6), or the Baptist St John (Luke, i. 35), sanctified before her birth—i.e. purified in her mother's womb from the stain of original sin; or by the still higher sanctification of having been entirely exempted from the stain of sin, either before the formation of the embryo in the womb of her mother, or at least before its animation by union with the soul. The actual controversy in the West may be said to have commenced with St Bernard, who not only remonstrated with the canons of Lyons in 1131 for their unauthorised introduction of this festival in their cathedral, but rejected the opinion of the Blessed Virgin's having been conceived free from original sin, though he admitted her sanctification in her mother's womb. Duns Scotus, in a disputation held before the university of Paris in 1307, maintained the doctrine of the immaculate conception in its highest sense; and the entire order to which he belonged, the Franciscan, as well as the school to which he has given his name, the Scotists, afterwards zealously defended it. The Thomist school, which was that of the Dominican order, denied the immaculate conception, and much division for a time existed; but the prevailing tendency was at all times towards the Scotist opinion. The university of Paris in 1387 condemned the Thomist doctrine. The Council of Basel—although, it is true, at the time when it was in conflict with the pope—declared the doctrine of the immaculate conception to be a Catholic dogma, and reprobated in the strongest terms the

opposite opinion. Sixtus IV., however, imposed on the defenders of both opinions in 1470 the obligation of mutual toleration and charity, and renewed this constitution in 1483; but the university of Paris required from doctors graduating an oath that they would defend the dogma of the immaculate conception. The Council of Trent merely declared that 'in its decree on original sin it did not comprehend the blessed and immaculate Virgin Mary,' and renewed the constitution of Sixtus IV. This abstinence on the part of the council led to a further renewal of the dispute, which reached such a pitch towards the close of the 16th century that Pius V. not only prohibited either side from stigmatising the opposite with the name of heretical, but forbade all public discussions of the subject, except in theological disputations in the presence of a learned auditory. In the pontificates of Paul V. and Gregory XV. earnest requests were made by the Spanish crown to obtain a definite declaration in favour of the doctrine of the immaculate conception; but the pope again refused, contenting himself with repeating the constitution of Sixtus IV. He added, however, certain new provisions: (1) That disputants, in asserting the doctrine of the immaculate conception, should abstain from assailing the opposite doctrine. (2) That no one except the members of the Dominican order, and others specially privileged, should presume to defend, even in private disputation, the doctrine that the Blessed Virgin Mary was conceived in original sin. (3) That, nevertheless, in the public mass or office of the church, no one should introduce into the prayers or other formularies any other word than simply *conceptio*, without adding any epithet involving either doctrine. At the same time opinion was setting steadily in favour of the doctrine of the immaculate conception. Alexander VII., and afterwards Clement IX., added new solemnity to the festival. Clement XI. ordained that it should be observed as a holiday of obligation, and at length Gregory XVI. permitted that the epithet immaculate should be introduced into the public service. In the end, at the instance of bishops in various parts of the church, Pope Pius IX. addressed a circular to the bishops of each nation, calling for their opinion, and that of their people, as to the faith of the church on the point; and on the receipt of replies all but absolutely unanimous, he issued a solemn decree at Rome, in a numerous council of bishops, on the 8th December 1854, declaring the doctrine to be an article of Catholic belief, and proposing it as such to the universal church. This decree has been universally accepted throughout the Roman Church.

Immanence, the constitutive pervasion of the universe by the Deity (not a transcendent creator or ruler), a fundamental conception of Pantheism (q.v.).

Immanuel. See EMMANUEL.

Immermann, KARL LEBERECHT, dramatist and humorist, was born at Magdeburg on 24th April 1796, and educated at his native town and at Halle, where he opposed the duelling *Burschenschaften* (q.v.). In 1817 he entered the public service of Prussia, and, after serving at Münster, Magdeburg, and Düsseldorf, died at the last-named town on 25th August 1840. For twenty years of his life (1819-39) he was greatly influenced by the Countess von Ahlefeldt, an intellectual lady of literary tastes. Immermann began his literary career as an adherent of the Romantic school, and in the spirit of that school wrote the comedies *Die Prinzen von Syrakus* (1821) and *Das Auge der Liebe* (1824), and the tragedies *Das Thal von Ronceval* (1822), *König Periander* (1823), and others. His later dramatic works, as the trilogy

Alexis (1832) and the mythical piece *Merlin* (1831), show more originality and fewer traces of Romantic influence. He failed in an endeavour to make the theatre at Düsseldorf, of which he became director in 1835, a model of classic elegance and healthy influence. His fame rests more enduringly upon his tales (*Miscellen*, 1830) and the humorous, satirical novels *Die Epigonen* (1836) and *Münchhausen* (1839), this last the best known of his works and one of the best of German novels. The idyllic portion of *Münchhausen* has often been printed separately under the title *Der Oberhof*. Besides these he wrote a mock-heroic poem *Tuldufschchen* (1827), the epic *Tristan und Isolde* (1842), and *Memorabilien* (1840-43), the last two left incomplete. Collected editions of his works were published in 14 vols. (1840-43), and in 20 vols. by Boxberger (1883). See Life by his widow, edited by G. von Putlitz (2 vols. 1870).

Immersion. See BAPTISM. An immersion lens is a microscope objective which has a drop of liquid between it and the cover-glass, so as to avoid loss of light by reflection. Water was used at first, and afterwards an oil with the same refractive index as the glass.

Immigration. As a form of migration (the act of changing residence) from one country to another, the facts of immigration and Emigration (q.v.) during our own time have acquired supreme international importance. Viewed historically, the filling up of new countries in the past was the by-product of international change resulting from civil or foreign war undertaken for dynastic, religious, or political purposes; not the result of immediate pressure of population on food-supply. The immigration of Huguenot families from France and the Low Countries to Great Britain, the settlement in South Africa both of French refugees after the Revocation of the Edict of Nantes, and of German emigrants in the Eastern Province of the Cape of Good Hope (q.v.) after the disbandment of the German Legion enlisted for service in the Crimean war, are examples of immigration due to causes other than intolerable pressure upon food-supply.

Since 1880 the influx of Semitic inhabitants of eastern Europe to North and South America and to Great Britain and her possessions has seriously affected the economic position of land-workers in certain trades. These phenomena, however important, are insignificant when compared with the gravity of the problem presented by the existence on the same planet of vast empty spaces under the control of people who make little or no use of the vacant land, and the presence of rapidly increasing populations pent up in central Europe or in Japan, China, and India.

The restriction of Mongolian immigration into Australia and the United States depends upon the naval and military capacity of the white peoples inhabiting countries washed by the Pacific Ocean to resist the compulsory expansion imposed on the Mongolian races by the natural increase of their populations, and by their adoption of Western standards of comfort and of naval and military efficiency. Laws aimed against the Japanese, as in 1920 in California, and the competition of the United States and Japan for sea-power, are but two symptoms of the same disease. The population of Australia (excluding the few full-blooded blacks), according to the census of 1921, was 5,435,734. The area of Australia is 2,974,000 square miles. Its wealth is concentrated largely in four vulnerable coast cities. Two-fifths of the inhabitants of the continent, which matches Europe in size, dwell in those four cities. Within a few days' steam of Australia live half the human race, congested,

hungry, ambitious, and waking from the long sleep of Asia. China contains four hundred millions of people. China is half the size of Australia. India contains three hundred and nineteen millions of people. India is two-thirds the size of Australia. Japan contains sixty millions of people, and is one-eighteenth the size of Australia. Japan must either secure homes for her immigrants or perish. Only one-eleventh of the soil of Nippon is cultivable. Increased and increasing accommodation for immigrants is not merely desirable; it is life or death to Japan. The Mongolian must secure immigration facilities or millions will perish. The Northern Territory of the Commonwealth is more than twice the size of France, having an area of 523,620 square miles, but it contains about seven inhabitants to a thousand square miles. Two-thirds of Western Australia and more than two-thirds of South Australia are equally sparsely populated. Australia is able to support two hundred millions of white men, and, while white immigration has been restricted, the influx of the Mongol race into the empty continent is only prevented by considerations of international politics.

Australia bars no race, but maintains control of immigration by means of the dictation test and rules under which imbeciles, persons suffering from certain diseases, and others detailed are, under the Immigration Acts, 1901-1920, debarred from admittance. Following the example of the United States, the Commonwealth imposes restrictions on immigrant manual labour under contract. If the immigrants are British subjects, the contract must provide for the rate of wages current at the proposed place of employment, and must not be made for the purpose of breaking a strike. If they are not British subjects, the employer must also certify that it is difficult to obtain equally skilled labourers within the Commonwealth. If these conditions are broken, the contract is declared void, and the employer must maintain the immigrant in Australia until he obtains other employment, or must, if the immigrant prefers it, provide the money to send him home again. 207,571 immigrants were admitted in the years 1911-20.

The law of New Zealand requires that all Chinese proposing to land in the Dominion be able to read a printed passage of not less than a hundred words in the English language. The Immigration Restriction Act (1908) further prohibits the landing of lunatics or idiots, persons suffering from dangerous or loathsome contagious diseases, certain convicted criminals, and any persons, not of British birth, who are unable to fill up and sign a prescribed form in any European language.

Canada presents at the present time the most enlightened policy of immigration hitherto established. Canada refuses to accept undesirable immigrants, but facilitates free entry of all white men likely to build up Canadian nationality. Canada rigorously excludes coolie labour and undesirables of all races. In this policy of restriction Canada has followed the example of the United States.

Under the American Immigration Law of 1924, which is in addition to and not in substitution for the act of 1917 (amended in 1920), the number of persons entering the United States from any country must not in any one year exceed 2 per cent. of the number of persons of that nationality already resident in the United States. The total admissions are not to exceed 150,000. These restrictions allow a very small number of immigrants from the British Dominions of Australia, New Zealand, and South Africa; the two latter were permitted to exceed this quota by 38 per cent. and 59 per cent. respectively in 1922.

Aliens who are anarchists or who belong to affiliated societies preaching the overthrow of law

and order as constituted in the United States are forbidden entrance.

With regard to the Japanese, only those eligible for citizenship in special cases are admitted, the total number for one year not to exceed 100.

The quota of Great Britain and Northern Ireland for the year from 1st July 1924 is 34,007, and for the Irish Free State 23,567. Within the limit stated, there is a preference granted to skilled agriculturists and to certain relatives of American citizens. The new law classifies arrivals into immigrant and non-immigrant, and the restrictions apply only to the immigrant class, and do not limit government officials, their families and employees, visitors, transit passengers, merchants; while students, ministers, returning aliens, and those living in contiguous territory—Cuba, Central and South America—are given certain freedom from restrictions.

In the United Kingdom an Aliens Act was passed in 1905 regulating the immigration of aliens, excluding any undesirable who (1) cannot support himself or his descendants; (2) is a lunatic or an idiot, or is diseased or infirm; (3) is a criminal; (4) has had an expulsion order made against him. An alien refused permission to land can appeal to the immigration board. Want of means is not to keep out an alien who is fleeing from religious or political persecution. An expulsion order may be made against alien criminals or aliens who, within twelve months of landing, become paupers or are without visible means of support. The shipping company bringing him over has to return at its own expense an alien expelled within six months of landing. For later legislation, see ALIEN.

See also COOLIES, EMIGRATION, NATURALISATION, SWEATING SYSTEM. For the *Volkerwanderung*, see EUROPE (*Historical Geography*), GERMANY (*History*), ROME (*The Empire*), and the articles on the various nations concerned, as AVARS, FRANKS, GOTHES, HUNS, VANDALS. For the conditions affecting the immigration of the lower animals and plants, see GEOGRAPHICAL DISTRIBUTION; and for their periodic movements, see MIGRATION.

Immingham, 4 miles NW. of Grimsby (q.v.), has a great railway dock (1912).

Immorality, in point of law, is a good defence to actions and suits, and obligations and contracts made against good morals are ineffectual at law. Thus, for example, if a man gave a bond, or granted a deed, giving to a woman some annuity, with a view to induce her to live in concubinage, this would be a good defence against the bond or deed being enforced, for the law discountenances his conduct; whereas, if it were merely a bond, or a gift, in consideration of something of the same kind past and ended, the deed would be good. So the keeper of a house of ill-fame is not allowed to sue, and has no legal remedy against her guests for any sum agreed to be paid for immoral purposes.

Immortality is the continued existence of the human soul in a future and invisible state. 'If a man die, shall he live again?' is a question which has naturally agitated the heart and stimulated the intellectual curiosity of man, wherever he has risen above a state of barbarism, and commenced to exercise his intellect at all. The religion of all civilised peoples may be said more or less to recognise the affirmative of the question, although often under very vague and materialistic forms. Some of the most widely-spread forms of belief in the world would seem to be exceptions to this statement; for in Hinduism the goal sought is absorption into the Universal Spirit, and therefore loss of individual existence; while the pious Buddhist strives for *Nirvana*, or complete extinction. Yet even here the belief in a future life exists in the form of Transmigration (q.v.).

In the ancient Egyptian religion the idea of immortality first assumes a definite shape. There is a clear recognition of a dwelling-place of the dead and of a future judgment. Osiris, the beneficent god, judges the dead, and 'having weighed their heart in the scales of justice, he sends the wicked to regions of darkness, while the just are sent to dwell with the god of light.' The latter, we read on an inscription, 'found favour before the great God; they dwell in glory, where they live a heavenly life; the bodies they have quitted will for ever repose in their tombs, whilst they rejoice in the life of the supreme God.' Immortality is plainly taught, but bound up with the idea of the preservation of the body, to which the Egyptians attached great importance, as a condition of the soul's continued life; and hence they built vast tombs, and embalmed their bodies, as if to last for ever. In the Zoroastrian religion the future world, with its governing spirits, plays a prominent part. Under Ormuzd and Ahriman there are ranged regular hierarchies of spirits engaged in a perpetual conflict; and the soul passes into the kingdom of light or of darkness, over which these spirits respectively preside, according as it has lived on the earth well or ill. Whoever has lived in purity, and has not suffered the *divs* (evil spirits) to have any power over him, passes after death into the realms of light. In the early Greek paganism Hades, or the realms of the dead, is the emblem of gloom to the Hellenic imagination. Achilles, the ideal hero, declares that he 'would rather till the ground than live in pale Elysium.' This melancholy view of the future everywhere pervades the Homeric religion. With the progress of Hellenic thought a higher idea of the future is found to characterise both the poetry and philosophy of Greece, till, in the Platonic Socrates, the conception of immortality shines forth with impressive clearness and precision. In the *Apology* and the *Phædo* Socrates discourses of the doctrine of the soul's immortality in language at once rich in faith and in beauty. 'The soul, the immaterial part, being of a nature so superior to the body, can it,' he asks in the *Phædo*, 'as soon as it is separated from the body, be dispersed into nothing, and perish? Oh, far otherwise. Rather will this be the result. If it take its departure in a state of purity, not carrying with it any clinging impurities of the body, impurities which during life it never willingly shared in, but always avoided, gathering itself into itself, and making the separation from the body its aim and study—that is, devoting itself to true philosophy, and studying how to die calmly; for this is true philosophy, is it not?—well, then, so prepared, the soul departs into that invisible region which is of its own nature, the region of the divine, the immortal, the wise, and then its lot is to be happy in a state in which it is freed from fears and wild desires, and the other evils of humanity, and spends the rest of its existence with the gods.'

It is only in Christianity, however, that this higher life is clearly revealed as a reward, not merely to the true philosopher, but to every humble and pious soul; Christ 'brought life and immortality to light by the gospel.' In Christianity the doctrine of the soul's immortality is a recognised truth, a light to the reason, and a guide to the conscience and conduct. For a contrast between the eternity of the absolute and infinite soul and the impermanence of the finite soul, see Bosanquet's Gifford Lectures on *The Value and Destiny of the Individual* (1913). For the Old Testament view, see the article HELL; for other questions connected with the future state, see the articles ANIMISM, APPARITIONS, CONDITIONAL IMMORTALITY, HEAVEN, ESCHATOLOGY, ORIGIN, PRE-EXISTENCE, SOUL, SPIRITUALISM. Imola, a town of Italy on an islet in the river Santerno, in the midst of a fruitful plain, 22 miles SE. of Bologna by rail, with spinning-mills and manufactures of glass and pottery. Its cathedral has been spoiled by restoration. Pop. 37,000.—Innocenzo da Imola (properly Francucci), a notable painter, was born here in 1494, and did most of his life's work in Bologna, where he died about 1550.

Impanation (Lat. *in*, and *panis*, 'bread'), a technical word formed on the analogy of 'incarnation,' employed in eucharistic controversies as early as the 12th century to express the union of the body of Christ with the consecrated bread in the Eucharist; but later specially used of Luther's doctrine of Consubstantiation (q.v.). See LUTHER, and LORD'S SUPPER.

Impeachment, an exceptional form of process whereby the House of Commons may obtain redress for any unlawful act, and especially for high crimes and misdemeanours committed by peers and ministers of the crown. When the House has resolved on an impeachment, certain of its members are deputed to go to the bar of the House of Lords, and there to present the charges they are prepared to support. At the trial the Lords as a body act as judges, the managers appointed by the Commons conduct the prosecution, and the accused may be defended by counsel. For a picturesque description of these proceedings, see Macaulay's *Essay on Warren Hastings*. A pardon by the crown may not be pleaded in bar of an impeachment; but after conviction and sentence the crown may pardon the offender. The last instance of an impeachment is that of Lord Melville in 1805. Impeachment is a form of trial, and is to be distinguished from proceedings by way of Bill of Attainder or Bill of Pains and Penalties. Parliament deals with such bills in its legislative and not in its judicial capacity. In the United States impeachment is a written charge brought by the House of Representatives to the Senate against a civil officer of the United States; or, in the several states, the accusation of an officer by the legislature to the senate of the state. The most famous trial of impeachment in the United States was that of President Johnson (q.v.).

Impenetrability, one of the essential properties of matter, implies that no two bodies can at the same time occupy the same space. If a nail be driven into a piece of wood, it does not, properly speaking, *penetrate* the wood, for the fibres are driven aside before the nail can enter. If a vessel be filled with fluid, and a solid body be then placed in it, as much water will run over as is equal in bulk to the solid body, in this way making room for it. The lightest gases are really as impenetrable as the densest solid; although, owing to their compressibility, it is not readily made apparent.

Imperial Cities. See FREE CITIES.

Imperial Conference. See CONFERENCE.

Imperial Defence. THE COMMITTEE OF, instituted in 1904 to advise from the point of view of the navy, the army, and the states of the

empire, comprises representatives of the government, the navy, and the army.

Imperial Institute, designed to commemorate the jubilee of Queen Victoria (1887), is by arrangement since 1907, and by act of parliament since 1916, administered by the Colonial Office. It promotes the utilisation of the commercial and industrial resources of the empire; arranges exhibitions of natural products in the galleries; provides for the investigation of new or little-known products from the Colonies and India by its scientific and technical department; gives scientific and technical advice on matters connected with their agriculture, trade, and industries; and issues reports and bulletins. There are a library and reading-rooms, and conference-rooms for meetings on matters connected with the empire. Lectures are given. Part of the building, which is in South Kensington and was opened in 1893, is occupied by the University of London.

Imperialism, as expressed in the great designs of Charlemagne (q.v.), amounted simply to a scheme of undisputed sway over an extensive area of continuous territory—autocracy on a grand scale. In that sense we find imperialism in the traditional policy of the tsars of Russia—a policy supposed to imply continuous expansion to the east. But imperialism, as it came to be known in connection with Germany, does not imply conquest or aggression or annexation of territory. In Germany the policy sprang from the Franco-German war, or rather from the events preceding it, and it meant simply the union, or reunion, of the several German states and peoples under one head for purposes of offence and defence, and for certain fiscal and political purposes. The use of the word in British politics is usually traced to Lord Beaconsfield and his large dreams of empire for the British crown. Of late, however, the word is generally meant to imply the combined interests of the mother-country, the dominions and dependencies—as distinguished from purely national, colonial, or local concerns. The character and design of such British imperialism were emphasised by the developments associated with the South African war of 1899-1902; and a special element was introduced into the discussions of imperial policy by Mr Chamberlain's campaign in 1903-8 on behalf of preferential tariffs. Anti-imperialists, when called by their opponents 'Little Englanders,' return the compliment by denouncing 'Jingoism.' Lord Rosebery in 1899 defined 'sane imperialism' (as opposed to 'wild-cat imperialism') as 'nothing but this—a larger patriotism.' Socialists, and persons of kindred schools of thought, look askance upon imperialism (British or other) as a policy of exploitation for the enrichment of financiers, entangling nations that are allured by it in a militaristic machine. See ABSOLUTISM, AUTOCRACY, CHAUVINISME, COLONY, EMPEROR, FEDERATIONS AND UNIONS.

Impetigo Contagiosa, a disease of the skin. It consists of crops of pustules, which may either be scattered or collected in groups. These pustules burst, dry up, and become covered with scabs or crusts of a yellow colour, not unlike little masses of candied honey. From beneath these crusts a purulent discharge commonly exudes; the crusts become thicker and larger, and the skin beneath them is red and raw. The disease is most common in childhood, and generally arises in ill-fed, ill-cared-for children; but it may be transmitted by contact to adults. The head and face are most commonly affected. Local treatment consists in removal of the crust by poulticing, and application of white precipitate ointment. Attention must be paid to

general health; and it must be remembered that the eruption is very infectious among children.

Impey, SIR ELIJAH (1732-1809), studied at Cambridge. Sent to Bengal as chief-justice (1774), he worked in harmony with Warren Hastings (q.v.), and in 1775 presided at Nuncomar's trial. Recalled and impeached, he was honourably acquitted.

Impotency. See MARRIAGE.

Impressionism, the term applied to a modern school of art which, originating in France, is usually held to have been founded by Edouard Manet, and of which Boudin, Claude Monet, Degas, Renoir, Pissarro, Sisley, Berthe Morisot, and Cézanne are the best-known members. The impressionists may be said to have first appeared before the public in the special exhibition of the works of Manet and his followers which was held in Paris in 1867; and in 1874 and 1876 collections of their works were brought together in the Boulevard des Italiens and in the galleries of Durand Ruel, who in 1882 organised an exhibition of their productions in London; while a series of works by Monet were shown in 1889 in the Goupil Gallery, London. The aim of the impressionists is to rid themselves of the trammels of artistic tradition, and to look at nature—and portray her—in a fresh and original manner. They therefore strive to avoid such compromises and conventionalities of lighting, composition, &c. as have been frankly accepted by the art of the past, and to render with absolute truth their personal and immediate 'impressions' of nature. The members of the school accordingly separate themselves in some degree from the great so-called 'romantic' art of Corot, Decamps, Rousseau, and Daubigny—a legitimate and orderly development of the mighty art of the past; and—though they have more kinship with these—they have also been distinguished from the *plein-air* painters of modern France, such as Bastien-Lepage, whose main aim is a careful and strictly scientific accuracy in their relative tones of colour. Pure colour and luminousness are, however, among the aims of the impressionists. Instead of mixing their pigments, they place them side by side on the canvas. Of this practice the pointillism of Seurat and Signac is an offshoot. In their rejection of tradition and desire for a fresh, unconventional rendering of nature the impressionists are at one with the pre-Raphaelites of England; but, while the latter studied nature in a severely detailed and analytical manner, the former look on her in her large relations, and portray only such of her salient features as are visible on a cursory examination, and these they render by brushwork of the slightest, thinnest, and loosest description. From the pre-Raphaelites the impressionists are still more definitely separated by their want of care for intellectual or emotional interest in their pictures. In the words of one of their ablest exponents, they hold that the eye of the painter 'should abstract itself from memory, seeing only that which it looks upon, and that as for the first time; and the hand should become an impersonal abstraction, guided only by the will, oblivious of all previous cunning.' In the works of some of the impressionists little selection of subject or care for beauty of colour, form, or expression is visible; and their art, touching as it would seem by an instinctive preference on some of the most unlovely aspects of existence, dealing with the life of the jockey and the ballet-girl, and portraying the worst atrocities of modern costume, often fell into dire depths of ugliness. Velasquez is claimed as an exponent of true impressionism (as opposed to pre-Raphaelitism); and points of resemblance are found in the works of such different

painters as Whistler and J. S. Sargent. Still more revolutionary than the impressionists, and even more vehemently denounced for lack of all artistic quality, are the 'post-impressionists,' neo-impressionists, or expressionists, who seek to express the inner nature of things—notable amongst them Gauguin, Van Gogh, Matisse, and Picasso; Cézanne and Madame Morisot being connecting links.

Impressment. See PRESSGANG.

Imprisonment is one of the three great punishments for crime, death and penal servitude being the others. The punishment of whipping also may be adjudged to juvenile offenders or persons convicted of assaults with violence. It has always been a power inherent in courts of justice to imprison for contempt of their authority, and until 1880 for non-payment of debt. In criminal proceedings a person may, by a warrant of a justice of peace or magistrate, be imprisoned before trial, provided the justice considers it is not a proper case for allowing bail; and though in minor offences an accused person may insist on being discharged on tendering sufficient bail, yet in more serious crimes it is in the discretion of the justice to accept or refuse the bail tendered, and on his refusal application may be made to judges of the common law courts to accept bail. In Scotland, when such review is resorted to under the Criminal Procedure Act of 1887, or the Act to amend the Law of Bail, 1888, the court rarely interferes with the magistrate's or sheriff's grant or refusal of bail, and in England the same rule obtains. In both countries the supreme courts will interfere where the question is merely one of amount, or where malice or oppression on the part of the prosecutor is averred; but in Scotland, owing to the system of official as distinguished from private prosecution, such grounds are rarely advanced in support of an application for bail. Imprisonment may be with or without hard labour, or it may be solitary. Every prisoner sentenced to undergo a long term passes a period in solitary confinement, and it is in the power of prison governors to order a return to this, which is considered the hardest part of the term, for any gross breach of discipline. The limit of imprisonment in practice is two years. Penal servitude may be inflicted for life, or any shorter term, but in the case both of imprisonment and penal servitude the convict can at any time, and repeatedly within certain limits, apply to the Home Secretary in England, and to the Scottish Secretary in Scotland, for commutation or remission. The documents are forwarded to the judge who tried his case, and the secretaries are guided in their decision by the report which the judge furnishes. In the general case a fourth or a third is deducted from all terms of penal servitude as a matter of course where the convict has complied with prison rules. In police and other petty offences tried summarily at common law and under a variety of statutes, imprisonment is usually awarded with the option of a fine (discretionary in amount), excepting the case of theft; but all other offences tried before recorder and quarter sessions in England and the sheriff and jury in Scotland are visited with imprisonment, although in a few isolated examples statute gives an option. The unlawful detention of the person by any one,

or 'false imprisonment' (in Scotland, 'wrongous'), constitutes a personal injury, and may be treated as a criminal or as a civil offence. When persons tried and convicted are afterwards proved to have been innocent, compensation may be awarded to them, along with a formal 'pardon.'

The subject of imprisonment for debt is discussed at DEBT, and at PRISONS.

Impromptu. See IMPROVISATORI.

Improper House. See PROSTITUTION.

Impropriation, the transfer to a layman of the revenues of a benefice to which the cure of souls is annexed, with an obligation to provide for the performance of the spiritual duties attached to the benefice. The practice of *impropriation* differs from the somewhat similar but more ancient usage of *appropriation*, inasmuch as the latter supposes the revenues of the appropriated benefice to be transferred to ecclesiastical or quasi-ecclesiastical persons or bodies, as to a certain dignitary in a convent, a college, a hospital; while *impropriation* implies that the temporalities of the benefice are enjoyed by a layman. The practice of *impropriation*, and still more that of *appropriation*, as in the case of monasteries, &c., and other religious houses, prevailed extensively in England before the Reformation; and on the suppression of the monasteries all such rights were vested in the crown, and were by the crown freely transferred to laymen, to whose successors in title they have passed by descent and purchase. The spiritual duties of such rectories are discharged by a clergyman, who is called a vicar, and who receives a certain portion of the emoluments of the living, generally consisting of a part of the glebe-land of the parsonage, together with what are called the 'small tithes' of the parish. A lay impropiator is rector of the parish; as such he has rights over the chancel of the church, and is bound to keep it in repair.

Improvisatori, an Italian term, in modern spelling *improvvisatori*, designating poets who without previous preparation compose on a given theme, and who sometimes sing and accompany, or musicians who perform extemporaneously. The talent of improvisation in verse is found in races in which the imagination is more than usually alert, as among the ancient Greeks, the Arabs, and in many tribes of negroes. In modern Europe it has been almost entirely confined to Italy, where Petrarch, in the 12th century, introduced the practice of singing improvised verses to the lute; and down to the present day the performances of improvisatori constitute one of the favourite entertainments of the Italians. Far inferior to these are such improvisations as those of Theodore Hook, wonderful as they were. Women have frequently exhibited this talent in a high degree. Improvisation is by no means limited to brief poems of a few verses and of very simple structure, but is often carried on with great art, and in the form and to the length of a tragedy or almost of an epic poem. But such productions when printed have never been found to rise above mediocrity. It is worthy of notice that the greater number of the celebrated improvisatori of Italy have been born in Tuscany or the Venetian territory. Siena and Verona have been especially productive of them. Some of the principal are Serafino d'Aquila (1466–1500); Perfetti (1680–1747); Metastasio (q.v.), who soon abandoned the art; Zucco (died 1764); Merio and Rossi (both beheaded at Naples in 1799); Gianni (pensioned by Bonaparte); and Tommaso Sgricci (1798–1836). The best-known *improvisatrici* are Maddalena Morelli Fernandez, also called Corilla Olimpica, the original of Madame de Staël's *Corinne* (died 1800), Teresa Bandettini (1763–1837), Rosa Taddei, Signora Mazzei (probably the

first in point of talent), and more lately the Sicilian Giovannina Milli (1827-88).

In music, skill in improvising is widespread. Bach, Beethoven, and the other masters have possessed it in high degree. The name *impromptu*, however, is often given to compositions not actually extemporaneous, but supposed to have the character proper to improvisations. Cadenzas were formerly left to the performer to improvise.

Imputation is one of the most common technical expressions in Christian theology. It is meant to denote the transference of guilt or of merit of punishment or reward. The doctrine of the imputation of sin, for example, is the doctrine which inculcates that all mankind are sharers in the fact and consequences of Adam's fall from innocence; and the correlative doctrine of the imputation of Christ's righteousness is that which inculcates that the merit or righteousness of Christ is transferred to those who believe in him, or, in other words, that they become sharers in his merit or righteousness. See COVENANT, ATONEMENT.

Imtiaz, a higher dignity than Pasha or Bey, instituted in Egypt on the establishment of the British protectorate.

Inaccessible Island. See TRISTAN DA CUNHA.

Incandescence. The hotter a body the greater the disturbance which its electrons, always oscillating, set up in the surrounding ether, and the greater is the proportion of ether-waves of short length which are set up. Thus, as a body becomes progressively hotter it first becomes visible in the dark as a fog-gray object (platinum at 390° C., gold at 417° C., and iron, not quite free from rust, at 377° C.—H. F. Weber), then ash-gray, then yellowish-gray, then faintly red, then red hot, orange, yellowish-white, white hot, and lastly, when there is at very high temperatures a preponderance of the more refrangible rays, it becomes bluish or even distinctly blue, as it seems the sun would appear were it not for our atmosphere (Langley). Incandescence is usually witnessed in solids; in liquids it does occur; but no substance perfectly transparent could incandesce. In gases true temperature-incandescence does not occur; the blue light of a Bunsen flame is not due to incandescence, but to chemical action, and the light of lightning or that from the gap in the electric arc is due partly to electric discharges through the air, partly to incandescence of dust-particles. The emissive power is related to the power of absorption; an ideal 'perfectly black' body would have a maximum emission; and this is experimentally realised by its equivalent, a heated hollow cylinder with a small hole at one end, which hole is treated as a source of heat or light radiated from the interior. According to Stefan's law, the total radiation from a hot body varies as the fourth power of the absolute temperature; according to Wien's first law, in the ratio in which we raise the absolute temperature, in the same ratio do we raise the frequency of that component of the spectrum which presents the maximum energy; and according to his second law, the amount of the maximum energy for such component varies as the fifth power of the absolute temperature. Wien and Planck have given laws for the estimation of the value of the energy of a given wave-length. It appears that within the limits of the visible spectrum, the total amount of luminosity varies as something ranging from the twelfth to the fourteenth power of the absolute temperature. Consult Preston's *Theory of Heat*. For Incandescent Electric Lamps, see ELECTRIC LIGHT; and for the incandescent gaslight, see GAS (LIGHTING BY).

Incantation, a formula of words said or more

frequently sung for purposes of enchantment. The use of such is a persistent feature in sorcery from the earliest times, and we still find them used among savage peoples as spells or charms efficacious for the healing of sickness and the averting of danger, as well as for bringing on rain or invoking any other blessing that is much desired. No less common are malignant spells by means of which evil deities are induced to send sickness or death upon enemies, the darker and malignant side of magic being ever as present to the primitive mind as the beneficent. Such traditional formulas show a marvellously conservative fixity of form—a proof, if such were needed, of their real unreality and practical inefficiency, and that the whole has at no time been other than a dark and blind appeal to unknown forces, without the slightest glimmering of scientific ratiocination, and capable of no improvement. For the same reason ancient or foreign epithets, and terms not merely misunderstood but not understood at all, are often found to have been particularly efficacious, and we find medieval sorcerers in their formulas using transposed letters and artificial words, the traditional Jewish names of demons, as Asmodai and the like, and a gibberish of mixed Hebrew and Greek words more or less consciously confused. Even so late as 1830 in Lincolnshire two Gypsy girls were found using a book of navigation in the process of their fortune-telling. The history of such words as the Gnostic *Abrazas* (q.v.) and the medieval *Abzacadabra* (q.v.) throws great light on the methods of magicians from the earliest ages down to the time when their absurdities disappeared before the dawn of a true scientific method. But it was not merely among the less civilised peoples that such constant use of incantations was made. In ancient Egypt magic was worked into an elaborate system and ritual, and many formulas of such religious magic are preserved. Again, the Babylonians had a great wealth of set formulas by means of which they propitiated or expelled the malignant demons who swarmed around them. In the *Vedas* we constantly meet the *mantras*, corresponding exactly to the *matamanik* of the Redskins and the *karakias* of the Maoris. In the *Odyssey* the kinsmen of Odysseus sing 'a song of healing' over the wound given him by the boar's tusk. In the *Kalevala* again we find the song that salves wounds; and nothing is more common in our European traditional folk-tales than the most startling miracles wrought by the repetition of snatches of rhyme. But indeed such traditional refrains are by no means yet extinct in the corners of the most civilised countries, used along with the modern and more legitimate methods of healing, and they even have a defensible use in the soothing effect that an act of faith has upon a simple mind. Thus in Shetland, according to a writer in the *New Statistical Account of Scotland*, 'when a person has received a sprain it is customary to apply to an individual practised in casting the "wresting-thread." This is a thread spun from black wool, on which are cast nine knots, and tied round a sprained leg or arm. During the time the operator is putting the thread round the affected limb, he says, but in such a tone of voice as not to be heard by the bystanders, nor even by the person operated upon:

The Lord rede, and the foal slade;
He lighted, and he righted.
Set joint to joint, bone to bone,
And snaw to snaw,
Heal, in the Holy Ghost's name.'

Incarnation, the usual theological term for the union of the divine nature with the human in the divine person of Christ. The word *incarnatio* first occurs in the Latin version of Irenæus, and in the Greek fathers we find its equivalent *sark-*

osis and *enanithrōpēsis*. See CHRIST, JESUS, and Ottley's *Doctrine of the Incarnation* (1896).

Incas. See PERU.

Incendiarism. See ARSON, EPIDEMIC.

Incense, a perfume, the odour of which is evolved by burning, especially in religious worship. The incense at present in use consists of some resinous base, such as gum olibanum, mingled with odoriferous gums, balsams, &c. There is no regular formula for it, almost every maker having his own peculiar recipe. The ingredients are usually olibanum, benzoin, styrax, and powdered cascarilla bark. These materials, well mingled, are so placed in the censer or thurible as to be sprinkled by falling on a hot plate, which immediately volatilises them, and diffuses their odour through the edifice.

In the Catholic Church, both of the West and of the East, incense is used in public worship, more particularly in connection with the eucharistic service, which is regarded as a sacrifice: but such use is implicitly condemned by Tertullian, Lactantius, Augustine, &c., and seems not to have established itself till the 6th or at least the 5th century. In the Roman Catholic Church incense is used in the solemn (or high) mass, in the consecration of churches, in solemn consecrations of objects intended for use in public worship, and in the burial of the dead. There are also minor incensations of the celebrating bishop or priest and inferior ministers; of prelates, princes, and other dignitaries officially present at the service; and a general incensation of the whole congregation.

In most of the Reformed churches the use of incense was abandoned at the same time with other practices which have been laid aside by them as without 'warrant of Scripture.' It was revived by some Anglicans, but was prohibited by the Archbishops of Canterbury and York in 1899; yet some clergy still insist that the use is incumbent on them as Anglican Catholics. See BOSWELLIA, CENSER, FRANKINCENSE, OLIBANUM; also MAGIC.

Incest is sexual intercourse between persons who are legally prohibited from marrying because of their Affinity (q.v.) or Consanguinity (q.v.). In Germany it is punished with penal servitude for from two to seven years, according to degrees and circumstances; so in Austria, Italy, and some other countries. But though incestuous marriages are utterly void in England, still it was left to be punished by the ecclesiastical courts (a punishment long obsolete), and was not a criminal offence till the passing of the act in 1908 which made intercourse with grand-daughter, daughter, sister, or mother punishable with penal servitude for from three to seven years or imprisonment for not more than two years with hard labour, irrespective of the female's consent. The female is punishable in the same degree, and the attempt to commit incest is a misdemeanour. 'Brother' and 'sister' include half-brother and half-sister. Till 1907 marriage with a deceased wife's sister was incestuous as well as void. In Scotland incest not only makes a marriage void, but was till 1887 punishable (nominally) with death, though usually only with penal servitude for life. Now penal servitude or imprisonment is the statutory punishment. In most of the American states incest is a statutory offence punishable by imprisonment up to ten years, under State laws. See MARRIAGE.

Inch, a Gaelic word, corresponding to Irish *innis*, and signifying Island (q.v.); the same root appears in Lat. *ins-ula*. Inch and Innis enter into many compounds, as Inchmahome (an island in the Lake of Menteith), Inniscattery (an island in the estuary of the Shannon), &c.

Inchbald, ELIZABETH, actress, dramatist, and novelist, was the daughter of John Simpson, farmer at Stanningfield, Bury St Edmunds, where she was born on 15th October 1753. While quite a girl she determined to become an actress, and when only eighteen left her home to seek a theatrical engagement in London. After a series of strange adventures she betook herself to her relations in London, and with them she met Joseph Inchbald, an obscure actor, whom she married on 9th June 1772. She then went to Bristol, where she made her début as Cordelia on 4th September 1772; and for some years she played in provincial theatres. Her husband died suddenly in 1779, and in 1780 (3d October) she appeared in London, playing Bellario in *Philaster*, at Covent Garden. Here she remained for nine years, but never rose beyond mediocrity, an impediment in her speech, which was, however, supposed to be cured, being certainly a bar to her progress. But before she left Covent Garden, in 1789, she had found her true vocation—literature, and to it she devoted herself till her powers began to fail. Her earliest efforts were plays, her first being *The Mogul Tale*, a farce produced in July 1784. She wrote or adapted nineteen plays, her best being the comedies of *Such Things are* (1787), *The Midnight Hour* (1787), and *The Wedding Day* (1794); the farces of *Appearance is Against Them* (1785) and *The Widow's Vow* (1786); and her adaptation from Kotzebue, *Lovers' Vows* (1793). She edited the well-known *Inchbald's British Theatre* (25 vols.), a *Modern Theatre* (10 vols.), and a *Collection of Farces* (7 vols.). But her fame rests not upon her dramatic work so much as upon her novels, *A Simple Story* (1791) and *Nature and Art* (1796), which rank among English standard novels. Mrs Inchbald, who was a Catholic, became very devout in her later years, and died at Kensington House (then a Catholic establishment), 1st August 1821. Her autobiography she destroyed by the advice of her spiritual director. See a German book by Clara Tobler (1910); and S. R. Littlewood, *Elizabeth Inchbald and her Circle* (1921).

Inchcape. See BRILL ROCK.

Inchcolm, an island of Fife, in the Firth of Forth, 1½ mile S. by W. of Aberdour, has a hermitage where Alexander I., driven thither by a storm, was entertained in 1123. In gratitude for the hermit's mussels and milk he founded the adjoining Augustinian abbey, whose well-preserved ruins include a plain chapter-house of great beauty. Bower the historian was among the abbots. Inchcolm is the 'St Colme's Inch' of *Macbeth* l. ii. Its picrite is of interest to petrologists.

Inchkeith, a strongly fortified island of Fife, in the Firth of Forth, 2½ miles SSE. of Kinghorn Ness. It has a lighthouse with fog-signalling apparatus. See LIGHTHOUSE.

Incidence, ANGLE OF. See OPTICS.

Incedon, CHARLES BENJAMIN (1763-1826), tenor ballad singer, born at St Kevern, Cornwall, served in the navy from 1779 to 1783. In 1784 he appeared at the Southampton Theatre as Alphonso in the *Castle of Andalusia*. From 1786 to 1790 he sang at Vauxhall Gardens and at Bath. In 1790 he appeared at Covent Garden Theatre as Dermot in the *Poor Soldier*; and for twenty-five years thereafter he remained unrivalled as a ballad singer. In 1817 he visited America. Afterwards he travelled through Britain under the style of the 'Wandering Melodist.'

Inclination, or DIP. See MAGNETISM.

Inclined Plane, THE, is reckoned one of the mechanical powers, because, by rolling it up a plane, a man may raise a weight which he could

not lift. Let us suppose a plane as in the figure: let its length, AB, its height, BC, and its base, CA, be respectively 13, 5, and 12 feet; and let a rolling load of 780 lb. be placed upon it and sustained

in position by a pull or push acting up the plane. We have now three forces in equilibrium: (1) the weight, W, of the body; (2) the resistance, R, of the plane to bending or breaking; and (3)

the pull, P, up the plane. These, W, R, and P, are respectively proportional to the length, AB, the base, CA, and the height, BC; and are thus, in the case supposed, respectively 780, 720, and 300 lb. A force which would, if applied vertically, just lift 300 lb., will thus keep a rolling mass of 780 lb. in position upon a smooth inclined plane, the gradient of which is 5 (height) in 13 (sloping length); and a force exceeding this would pull the mass up the slope. In every practical case, however, there is a certain force expended in overcoming Friction (q.v.), even on a dead level; in railway trains this is equivalent to vertically lifting about 50 lb. for every ton of dead weight; and when a train leaves a level run to go up a slope of, say, 1 in 80, the engine has then, for every ton of weight, to do work equivalent to vertically lifting 50 lb. + $\frac{1}{80}$ ton = 78 lb., instead of the former 50. The steeper the gradient, therefore, the heavier the pull; and engineers, in roadmaking, avoid as far as possible making steeper slopes than 1 in 20. The inclined plane presents various modifications, such as knives, chisels, axes, wedges, screws; the last two are generally reckoned as distinct mechanical powers, and are treated each under its own head.

Inclinometer. See DIPPING-NEEDLE.

Inclusores. See COMMONS.

In Cœna Domini, a celebrated papal bull, so called from the ancient day of its annual publication, Holy Thursday. It is not, as other bulls, the work of a single pope, but, with additions and modifications at various times, dates back to the middle ages. Its final form, however, it received from the popes Julius II., Paul III., and lastly Urban VIII., in 1627, from which year it continued for a century and a half to be published annually on Holy Thursday. It may be briefly described as a summary of ecclesiastical censures, especially of those with which grievous violation of the faith of the church, or of the rights of the church or of the Roman see, are visited; excommunication being denounced against heresy, schism, sacrilege, usurpation of the rights of the church or of the pope, forcible and unlawful seizure of church property, personal violence against ecclesiastics, &c. The bull, which also denounced other crimes, as piracy, plunder of wrecks, and forgery, was opposed by most of the crowned heads of Europe (even the Catholic ones) as an infringement of their rights, and was discontinued by Clement XIV. in 1770.

Incombustible Fabrics. See FIRE.

Income-tax, a tax directly levied on all persons having incomes above a certain amount, became an important feature in the British fiscal system during the French war in 1798. It was revived by Sir Robert Peel in 1842, and may now be regarded as permanent. It has always been objected to the tax that it bears an inquisitorial character through the officials of government making investigation into the private affairs of the citizens. Further, as the estimate of income must to a large extent be left to the discretion of the persons taxed, it

offers very considerable opportunity for concealment and falsification in the returns; while the conscientious render an account in full, the less scrupulous may pay less than they ought. On the other hand, equity is had regard to in that the tax is so far graduated; exemption is granted to small incomes, and deductions of varying amount on incomes above the level of exemption. In 1907 differential treatment (modified later) of earned and unearned incomes was introduced, and in 1909 a super-tax was imposed on large incomes. The law was consolidated by the Income-tax Act, 1918.

Italy established an income-tax in 1864, Prussia in 1891, Austria in 1849, New Zealand in 1893, the Cape of Good Hope in 1904. In Australia both Commonwealth and the states impose income-tax. Denmark, Holland, Norway, Spain, Switzerland have some form of income-tax.

In the United States an income-tax was imposed in the years 1863-71. An income-tax enacted in 1894 was declared unconstitutional by the Supreme Court in 1895 as being a direct tax, and so incapable of being levied except in strict proportion to the population of the several states. An amendment to the constitution of the United States, empowering Congress to levy an income-tax without reference to population, was accepted by Congress in 1909 and put before the State legislatures, and in February 1913 the votes of Delaware and Wyoming secured the necessary majority. See E. R. A. Seligmann, *The Income-tax: a Study of the History, Theory, and Practice* (1911).

Incommensurable. See COMMENSURABLE.

Incubation varies in duration in different species, but is nearly constant in each. In the humming-birds it is only 12 days; in canaries it is from 15 to 18 days; in the raven and in the common fowl, 21; in the duck, 28 to 30; in the pheasant and in the guinea-fowl, 28 or 29; in the turkey, 30; and in the swan, 40 to 45. The temperature (about 40° C., 104° F.) necessary for the development of the young is usually supplied by the mother-bird; but in some cases the sunshine (as in ostriches during the day), or the warmth of a nest of decaying plants (as in the Megapodes), is relied upon; nor must it be forgotten that in many Passerine and Running Birds the males take their share, or it may be the entire responsibility of incubation. While the patience of incubation is most emphasised and rewarded among birds, hints of it appear in reptiles—witness the female python; and analogous processes are seen in a few fishes, and even invertebrates.

Incubators, or devices for artificial hatching, are used both for practical and scientific purposes at the poultry-farm and in the embryological laboratory. From time immemorial the Egyptians have hatched eggs by artificial warmth in peculiar but comparatively simple ovens, and thirty millions of chickens per annum are said to be thus hatched in Egypt. In 1777 Bonnemain devised a hatching apparatus which supplied the Parisian markets with poultry. In 1825 D'Arcet obtained chickens from artificial incubation by means of the thermal waters at Vichy. The *Eccaleobion*, invented by Bucknell in 1839, was said to possess a perfect control over temperature from 300° F. to that of cold water. There are very many different kinds of modern automatic incubators, mainly hot-water or hot-air types, whose advantages and disadvantages are fairly balanced. The essentials are an egg-chamber uniformly heated, preferably from above; a self-regulating source of heat, controlled by a thermostat, the acting arm of which, within the egg-chamber, is sensitive to less than 1° above or below the desired temperature; and provisions for the ventilation of the egg-chamber and the maintenance

of the proper humidity therein. Modern incubators date from the hydro-incubator of the Paris Exposition of 1877; Hearson's is one of the best-known hot-water incubators, Hillier's of the hot-air type. There are special incubators for biological and bacteriological purposes; incubators for babies were used at the Paris Maternité in 1880; and improved 'nurses' of this kind are in use in British hospitals and poorhouses. See OSTRICH, POULTRY, PISCICULTURE.

Incubus. See DEMONOLOGY.

Incunabula, the earliest printed books, especially those published before 1500; see PRINTING.

Incus, one of the small bones of the ear. See EAR, and fig. 2 there.

Indecency is guarded against by the Criminal Law Amendment Act of 1887, the Indecent Advertisements Act of 1889, and the Obscene (q.v.) Publications Act of 1857. See also PROSTITUTION.

Indemnity, an instrument or contract whereby a person is protected against loss, or against the risk of legal proceedings. Fire insurance, for example, is a contract of indemnity; not so life insurance, which is a contract, not to make good an uncertain loss, but to pay a certain reversionary sum. Acts of indemnity are sometimes passed by parliament for the protection of public officers; thus, in 1801 and in 1817 acts were passed to protect officers who had taken part in the apprehension, &c., of persons suspected of treason. From the year 1727 onward general acts of indemnity were passed from time to time for the benefit of those who omitted to take the oaths of office required by the acts imposing disabilities on dissenters.

Indenture. See APPRENTICE, COOLIES.

Independence, a city of Kansas, 15 miles NNW. of Coffeyville, in a rich agricultural district, with coal, gas, and oil, manufactures biscuits, bricks, flour, ice, strawboard, cement, rubber, &c., and refines oil; pop. 12,000.—(2) A city of Missouri, 10 miles E. of Kansas City, has flour, iron, and oil industries, and trade in agricultural products; pop. 12,000.

Independence Day, in the United States, falls on the 4th of July, and is observed as a legal holiday, to celebrate the Declaration of Independence in 1776.

Independent Labour Party. See SOCIALISM; also HARDIE (JAMES KEIR).

Independents, or CONGREGATIONALISTS. The rise of the denomination bearing this name cannot be rightly appreciated apart from the main Protestant movement in England and on the Continent. The translation of the Bible into the speech of the common people, and the assertion of the right of private judgment, had their inevitable effect in a multitude of opinions and doctrines, some of which collapsed speedily, while others inspired deep conviction and attracted devoted adherents. It is not necessary to do more than to refer to the sporadic movements on the Continent which go by the name of Anabaptism, and were in the main the result of the social and spiritual unrest that preceded and followed the Peasants' War in the days of Luther. There were many similar abortive attempts made in England to organise discontent with the prelatical and authoritative church established by law, but for anything like a reasoned doctrine of the church such as is associated with the name Independency we have to wait for the writings and teachings of Robert Browne, who suffered thirty-two imprisonments for his opinions, and finally made submission, re-entered the Establishment, and ended his life ignominiously. The constructive writings of Robert

Browne lie between the years 1578, six years after his graduation at Cambridge, and 1586, the date of his recantation. Browne's position in history is due to the fact that he transformed a Puritanism that was a mere bundle of negations—opposition to vestments, ceremonies, prelates, and so forth—into a Puritanism that was based on a positive conception of the church. He protested that a church did not consist of all the people in a parish, but 'rather of the worthiest, how few soever they may be.' This led to the practical consequence of separation; and his followers were often called simply 'separatists.' In the logical development of his doctrine, he challenged the right of the magistrate to interfere with a spiritual society which was solely subject to the authority of Christ and the discipline of its self-chosen pastors and officers. His famous pamphlet on *Reformation without tarrying for anye* affirmed the right of such a church to undertake practical reformation without the authority of the Bishops or of the Privy Council. These truths he preached with fiery vehemence, and not always with perfect consistency; yet, in the main, he stated the church theory to which the Independents are still loyal. Browne was followed by men of a much higher type of character, who, so far from retracting their opinions, sealed them with their blood. The three best known were Henry Barrowe, John Greenwood, and John Penry. They were all university men, and they were all the victims of the narrow intolerance of Archbishop Whitgift. Barrowe was a man of good family, being distantly related both to Lord Bacon and Lord Burghley. Independency even in modern times would accept his definition of a church as 'a society of faithful men and women, wholly surrendered to Jesus Christ, walking forth in faith and obedience.' Greenwood, who had taken a priest's orders in the Church of England, held and taught that every believer in Christ was as much a priest as he was. These doctrines easily led, at that time, to accusations that the authors of them were 'levellers' and 'traitors.' The 'alone headship' of Christ in his church was assumed to imply disloyalty to the queen. Barrowe and Greenwood were flung into prison, and one of their titles to fame is in the notable writings which they succeeded in composing there, and, with infinite difficulty and peril, smuggling out of prison so that they could be printed and circulated. John Penry, the brilliant young Welshman, has association with the famous Martin Marprelate tracts, for the alleged authorship of which he was eventually executed. Barrowe and Greenwood were hanged at Tyburn on 6th April 1593. Their martyrdom was hastened by a famous debate in the House of Commons in 1592, when Sir Walter Raleigh declared that there were twenty thousand Brownists in England. The number was probably exaggerated; but it points to a very rapid spread of the Independent doctrine; and the extreme forms of coercion were employed to stamp out the new sect and the writings which had produced so great a ferment. The Conventicle Act of 1593 enacted imprisonment for those over sixteen years of age who refused to attend the Established Church, with a further provision of banishment if they persisted, and a final sentence of death if they returned from exile.

The next stage in the history of the Independents is the formation in 1602 in the Manor House at Scrooby, in Nottinghamshire, of a number of 'godly persons' into 'a church of the Congregational order.' This church has become famous because of the association with it not only of the Rev. John Robinson and the Rev. John Smyth, but of William Brewster and William Bradford, who were destined to become leaders in the movement that resulted in the American Commonwealth. The church at

Scrooby and the sister-church at Gainsborough were compelled to abandon their work, and the members, after extraordinary sufferings, made their way to the Continent, and finally re-established themselves in Leyden under the ministry of John Robinson, where they gave an example of an ideal Christian fellowship, free from the bigotries and fanaticisms which had disfigured previous attempts at 'separated churches.' Much was due to John Robinson's breadth of mind and catholic spirit. No story in the world is better known than how the members of the church finally decided to seek a new home across the Atlantic that, as Mr Lowell said, 'they might plant their idea in virgin soil.' John Robinson remained behind with the members who could not go so far; but on 22d July 1620 the *Mayflower* sailed, and on 16th November arrived at Cape Cod. Before landing, a solemn covenant was drawn up in the cabin, which Mr Bancroft declares is 'the first instrument conferring equal civil and religious rights on all members of the Commonwealth.' Governor Brewster, Governor Bradford, John Alden, Myles Standish, among others, have left names famous in the history of the world.

In England the penal laws made the religious organisation of the Independents very precarious, and tended to throw their strength into the civil struggle for religious liberty. They became, as is well known, the most powerful and uncompromising factor in the Parliamentary army, and were in the main true to Cromwell's rule, 'The state in asking a man to serve it takes no account of his opinions.' The Presbyterians complained that 'Toleration is the great Diana of the Independents.' The attitude of the latter was seen during the discussions on the Westminster Confession. They did not refuse to confess the Christian faith as they held it, but they refused to bind their consciences 'against any future change of doctrine.' This was entirely in harmony with John Robinson's farewell message to the Pilgrim Fathers, in which he charged them to believe that 'the Lord has yet more light and truth to break forth from his holy word.' The triumph of Independency under Cromwell, and with Milton for its sponsor on the intellectual side, is well known. It was singularly rich in great theologians of the type of Goodwin, Owen, and Howe. It was natural that when the Commonwealth came to an end at the Restoration, the Independents should be the chief sufferers at the hands of the ministers of Charles II. Of the two thousand clergymen ejected under the Act of Uniformity in 1662, a large number would probably have described themselves as Presbyterians rather than Independents; but they helped to swell the general Nonconformist movement in England and Wales; and when relief came to them by the Toleration Act they became the ministers of Independent congregations, so that the wider Congregationalism of to-day owes very much to them. In the 18th century further reinforcements came to them through the evangelistic work of George Whitefield. The Independents had always been Calvinists, and had based themselves on the doctrines of Geneva, though with strong reservations in favour of private judgment. Consequently, when George Whitefield broke from John Wesley on Calvinistic grounds, the societies gathered as a result of his ministry were drawn into closer sympathy with the older Independents; and in point of fact the large majority of them are to-day Congregational churches. Towards the close of the 18th century a movement for the establishment of foreign missionary work was inaugurated under the name of 'The London Missionary Society.' The society disclaimed any desire to make its converts Independents, Presbyterians, or Episcopalians, and was satisfied to make itself responsible for

furthering 'the Gospel of Christ.' This catholic basis was characteristic of the churches that mainly rallied to the support of the new society. To-day the London Missionary Society is almost wholly supported by Congregationalists. It has upon its roll of famous missionaries such great names as John Williams, Robert Moffat, David Livingstone, and Robert Morrison. Its work in China, India, Madagascar, the South Seas, and Southern and Central Africa has been extraordinarily successful.

Independency has never made much progress in Scotland, where its earliest churches were the result either of missionary journeys by such men as Robert Browne—who had little or no success—or by the Commonwealth soldiers, whose presence in Scotland was a symbol of conquest. Later on an evangelistic movement, which owed most of its inspiration to laymen, met with considerable response. Robert and James Haldane, by their earnest and sacrificial work, lent new strength to Independency. In quite modern times the 'Evangelical Union' was formed, representing a number of churches that sprang into existence as a result of the expulsion of the Rev. James Morison and others from the United Secession Church because of their anti-Calvinist teaching of a universal atonement. The new denomination adopted the Congregational order of government, and the Theological College presided over by James Morison had considerable influence in Scotland. In 1897 the Evangelical Union churches united themselves with the Congregational churches of Scotland in one denomination. In contrast to the comparative failure of Independency in Scotland, its success in Wales has been very remarkable. Possibly no denomination has exercised so powerful an influence on modern developments in the Principality. It has been prolific in great preachers, and enlightened in its emphasis of educational work.

As might be expected in a denomination whose principal founders were university men, and whose earliest literature included John Penry's *Plea for a Learned Ministry*, consistent emphasis has always been placed on education, and the contributions of Congregational scholars to theological, philosophical, and historical literature have been very conspicuous. Apart from the great works of Owen, Matthew Henry, Goodwin, Baxter, Howe, and others of the 17th and 18th centuries, the names of Dale and Fairbairn were equally eminent in the 19th century. Even during the years of the penal laws, when Nonconformist education was a matter of great difficulty, when the universities were the exclusive monopoly of the Church of England, and no school could be opened except with the licence of the bishop, every effort possible was made to maintain a high educational standard. To-day the Congregational public schools and theological colleges hold a very strong position. The English theological colleges are Mansfield College at Oxford, Cheshunt College at Cambridge, Hackney and New College in London, the United College at Bradford, Lancashire College at Manchester, the Western College at Bristol, and Paton College at Nottingham. In Wales the colleges of Brecon and Bala-Bangor have an honourable history. There is also a Theological Hall in Edinburgh. Among the public schools that are under distinctively Congregational or Free Church auspices may be mentioned Mill Hill, Caterham, Bishops-Stortford, Taunton, Tettenhall, and Silcoates.

But notable as have been the educational achievements of Congregationalism in England, they have been eclipsed in the United States, where most of the famous universities and colleges of New England are by foundation Congregational. Of these we may mention Yale University, Harvard University, Amherst College, Hartford and Andover Theological Seminaries. These are but a few out of many.

It is now generally recognised that the isolation of the old Independency was a weakness. This has been proved especially in the Colonies, where extraordinary necessities for church extension have had to be met. The lack of organisation and cohesion in Congregationalism has placed it at a disadvantage. In Australia and Canada it has had some powerful preachers, and has been at times influential in the general life of the Commonwealth, but it has been altogether outdistanced by denominations that had the advantage of closer connexional unity. Of recent years many successful efforts have been made to reconcile the principle of Independency with a connexional bond. The Congregational Union of England and Wales has become a very powerful body, and the various county associations have done much to prevent the intrusion into the ministry of men educationally unqualified. At the same time, the Congregational Union has always been careful to repudiate any power to impose a stereotyped creed upon its individual members, and has consistently maintained its historical tradition in this respect. An effort to secure the more adequate sustentation of the ministry by a central fund of £250,000 was successfully completed in 1912, and a movement to raise half a million for Congregational objects was afterwards inaugurated.

See Neal's *History of the Puritans* (ed. Toulmin, 1822); Waddington's *Congregational History* (1869-80); Vaughan's *English Nonconformity* (1862); H. W. Clark's *History of English Nonconformity* (1911); Burrage's *Early English Dissenters* (1912); Dale's *History of Congregationalism* (1907); Dexter's *Congregationalism as seen in its Literature* (1880); H. S. Skeats's *History of the Free Churches in England* (2d ed. 1869); Masson's *Life of Milton*; Dr John Brown's *Pilgrim Fathers of New England* (1895); and the *Congregational Year Book* (annual); also ENGLAND (CHURCH OF); PURITANS, and books there named; PRESBYTERIANISM, &c.; and the articles on the great Independent divines.

Index—the Index Librorum Prohibitorum or Expurgandorum—a catalogue published by papal authority in the Roman Catholic Church of books the reading of which is prohibited to members of that church, whether on doctrinal, moral, or religious grounds. As a natural consequence of the claim of the Catholic Church to authority in matters of religion, and to infallibility, that church also claims the right or the duty of watching over the faith of its members, and of guarding it against every danger of corruption, the chief among which is held to be the circulation of books believed to be injurious to faith or to morality. The earliest recorded exercise of this restrictive authority is the prohibition of the writings of Arius. The earliest examples of a prohibitory catalogue are found in a letter (405) of Pope Innocent I., and in the decree of a council held at Rome (494) under Pope Gelasius, which, having enumerated the canonical books of Scripture and other approved works, recites also the apocryphal books, together with a long list of heretical authors, whose writings it prohibits. The medieval popes and councils pursued the same course as to the heterodox or dangerous writings of their respective periods; and the multiplication of such books after the invention of printing led to a more stringent as well as more systematic procedure. The university press of Louvain issued in 1546, and again in 1550, a catalogue of prohibited books. Similar lists appeared by authority at Venice, Paris, and Cologne; and Paul IV. issued in 1557 and 1559 what may be regarded as properly the first Roman Index. One of the gravest undertakings of the Council of Trent was a more complete and authoritative enumeration of all those books the use of which it was expedient to prohibit. A committee was appointed for

the purpose. But it was found impossible to bring the examination of the books to an end before the close of the council; and the entire papers of the committee were handed over by the council to the pope, with instructions that the work should be completed, and the result published by his own authority, which was accordingly done by Pius IV. in 1564. Further additions and certain modifications of its rules were made by Sixtus V. and Clement VII.

The preparation of the Index, in the first instance, was committed to the care of the Congregation of the Inquisition in Rome; but a special Congregation of the Index was established by Pius V. (1571), and more fully organised by Sixtus V. This congregation consists of a prefect (who is always a cardinal), of cardinals, of consultants, and of examiners of books (*qualificatores*). Its proceedings have been governed by rules authoritatively laid down by several popes, especially by Benedict XIV. in a constitution issued July 10, 1753. The latter alone was retained by Leo XIII., who reorganised legislation in this respect by the constitution '*Officiorum ac munerum*' (1897) and the reform of the Index, published in 1900.

The prohibitions of the Roman Index are of two classes, either absolute and total or partial and provisional, 'until the book shall have been corrected.' The growth of modern literature has, of course, entirely outstripped the limited and tardy machinery of this tribunal. A very small proportion even of the most anti-Catholic publications outside of Italy appear by name in the Roman Index; but, besides the positive prohibitions of the Index itself, there are certain general rules regarding the use of books by which the freedom of what is considered perilous or pernicious reading is much limited among members of the Roman Catholic Church. Under the rules of Leo XIII. irreligious, heretical, superstitious, and immoral writings are forbidden, as are books insulting to God, the Virgin, the saints, the church, or the clergy. Works by heterodox authors are permitted, provided they contain nothing serious against the Catholic faith. Certain other classes of books are conditionally condemned; that is, they are forbidden unless permission has been obtained for their publication. These include editions or versions of the Bible, by Catholics or others; devotional, ethical, religious, and mystical books; and books containing religious novelties.

English authors whose names are or once were upon the Index include Chaucer, Spenser, Bacon, Sir Thomas Browne, Hobbes, Berkeley, Locke, Addison, Hume, Goldsmith, Sterne, Richardson, Macaulay, Mill, Hallam, Andrew Lang. In other languages we find Spinoza, Leibniz, Dante, Petrarch, Fogazzaro, Kant, Heine, Hugo, Michelet, George Sand. Until 1835 Copernicus, Kepler, and Galileo were forbidden, as were indeed till 1787 'all books which maintain that the earth moves and the sun does not.' The crusade against M. Loisy and 'Modernism,' culminating in a decree of the Holy Office and a papal encyclical (1907), has largely extended the Index. See Putnam, *The Censorship of the Church of Rome* (1907); H. H. Houben, *Verbotene Literatuur* (Berlin, 1924).

Indexing. The need of indexing has become more urgent as the mass of materials to be indexed has increased, and the circle of those who wish to use these materials has become wider. Lord Campbell proposed to bring a bill into parliament to deprive an author who published a book without an index of the privilege of copyright. There are two classes of books to be indexed—viz. books of facts and books of opinion. In the indexing of the first class, experience, care, and common sense are needed, and the work must be systematic and not casual. In the second class these qualifications are required and something else—viz. the insight of the

precis writer. The indexer must understand his subject and also understand the wants of the reader. The index must be exhaustive in its indication of the various points in the book, and concise in expression, and in addition the indexer must be careful in the choice of catchwords or titles for his headings. He must gather together the same subjects under one heading, and see that they are not separated under synonyms. An author frequently uses periphrases to escape from the repetition of the same fact in the same form; but these periphrases will give little information when inserted as headings in an index, and it is in this power of selecting the best catchword that the good indexer will show his superiority over the commonplace worker. The meaning of the word index has gradually grown from the general to the particular, and the word is now established as denoting a series of references arranged in alphabetical order. There are other kinds of indexes; but these require an explanatory adjective, as classified, chronological, &c. In indexing names it is most important to specify the cause of reference, as a block list of references after a name is almost useless. A colossal instance of this fault will be found in Ayscough's index to the *Gentleman's Magazine*, where all the references under one surname are placed together without even the distinction of the Christian name. There are 2411 entries under Smith, and it has been calculated that to go through this mass in order to find say Zachary Smith would take the consulter eight days of ten hours a day. It is also important to bring all the references to one man under one heading, and not to separate them under the different names or titles he may have borne. In the index to Scott's edition of Swift's Works there are 638 references to Harley, Earl of Oxford, arranged thus: 227 under Robert Harley, 111 under Lord Oxford, and 300 under Treasurer (Lord Oxford). There should be one index for a complete work and not a separate index for each volume. Again, no classification should be allowed in an alphabetical index. This vicious habit of classification makes the indexes of some well-known papers practically valueless. The consulter of the index wishes to find whether the volume contains anything on a particular subject, and he is only confused and annoyed if he has to look in a succession of alphabets arranged under such headings as original articles, notes, correspondence, &c. The preparation of an index consists of three divisions: (1) compilation, (2) arrangement, (3) printing. Each indexer will find out the mode of procedure which is most suitable for himself; but it may be said generally that foolscap paper is the most convenient size for use. Those entries which are not likely to be repeated can be written down on the page as they occur; but in the case of large headings it will be more convenient to use a separate page for each, and keep these pages in an alphabetised guard book so that they can be turned to in a moment. When the time comes to cut up the index and arrange it in alphabetical order, it will be necessary to see that there are no repetitions of the same subjects under various synonyms. Now is the time to make the cross references, and here considerable judgment is required. When the entries are short and few, it is better to repeat them than to refer from one to the other; but in the case of long entries cross references are very advantageous, and it is always well to refer to cognate headings. No reference to the contents of a general heading which is without subdivision should be allowed. If a general heading is divided into sections, and each of them is clearly defined, they should be 'cross-referenced,' but not otherwise. When the arrangement of the cut-up slips is undertaken, some alterations and revision

of headings will frequently be found advisable. The value of an index is greatly enhanced by the proper setting out of the entries with judicious use of different types. When a book is a complete treatise on a special subject, a well-made index will form an admirable key to the subject and be in itself intrinsically useful. Indexes may also be made with regard to a particular subject dealt with in a number of books.

The Index Society, to form a library of indexes, and to make indexes to important books, rare serials, &c., was founded in 1877, and subsequently incorporated with the British Records Society; their publications appear quarterly in the Index Library. The American Library Association Index (1893) indexed 3000 miscellaneous volumes. See books mentioned at BIBLIOGRAPHY; H. B. Wheatley, *How to Make an Index* (1902); and Miss Petherbridge, *The Technique of Indexing* (1905).

India, an extensive region of southern Asia, and next after China the most populous area in the world. It was celebrated during many ages for its riches and natural productions, its beautiful manufactures and costly merchandise, the magnificence of its sovereigns, and the early civilisation of its people. It possesses especial interest to British people from the imperial connection of its history with that of their own nation. It affords, too, the greatest market in the world for British textile manufactures, and a great field for the employment of British capital.

Nomenclature.—The name India comes to us, through the Romans, from the Greeks, who borrowed it from the Persians. The latter applied the name Hind to the dwellers in the basin of the Sindhu River, a Sanskrit name for the Indus. Sindhu, by the regular change of *s* into *h*, becomes Hind. The river is still called Sind; while the land is Hind. Officially, then, the country is Hind in the vernacular, and India in English. The national name Hindu is derived from Hind. Then from Hindu came the name Hindustan, which is only a province—viz. the region of the Jumna and the Ganges. This name has sometimes been applied to India as a whole, but this is quite erroneous.

Geographers write of Further India and Hither India. The former, lying eastward beyond the Malay Peninsula, is mostly in native hands, and partly under French protection. Almost all of the latter is under British dominion, and was in 1877 proclaimed as the Indian empire. This article will refer mainly to the official India thus indicated. It will for method and condensation be divided into six parts—I. The Land; II. The People; III. The Government and the Military Defence; IV. The Civil Administration; V. French and Portuguese India; VI. The History.

I. THE LAND.

India is the central peninsula of southern Asia, and lies in 8° 4'—35° N. lat. and 67°—92° E. long. According to these limits, its length may be stated approximately at 1900 miles, and its breadth, reckoned along the parallel of 25° N. lat., at 1600 miles, with an area of at least 1,350,000 sq. m. But in round numbers the square miles contained in this area may be reckoned at one million and three-quarters—inclusive of Burma. The natural boundaries of this vast region are, on the N., the range of the Himalaya Mountains, which separates it from Tataria, China, and Tibet; on the W. the Suliman Mountains, dividing it from Afghanistan, and the Persian frontier; on the SW. and S. the Arabian Sea and the Indian Ocean; on the E. the hill-ranges which border upon Burma, and the Bay of Bengal. From the mouths of the Brahmaputra on the eastern side, and of the Indus on the western side, the two coasts, east and west, incline towards the

same point, and meet at Cape Comorin, thus producing the form of an inverted triangle. The two sides of the triangle have together a coastline of about 2000 miles. Thus southern and central, or as it may be called peninsular India, is from its extent of seaboard a maritime country. It is northern India only that has a continental character.

Geography.—For the geography of India there exist excellent materials from the *Grand Trigonometrical Survey*—a work of the highest scientific value—which has determined the height of the mountains and the situation of all the principal places; from the topographical survey, which has displayed the contour and configuration of the whole country; from the revenue and cadastral surveys, which have delineated the boundaries not only of villages but of fields also for all provinces except Bengal. The region presents a diversified surface and scenery. It has indeed been called 'an epitome of the whole earth,' consisting as it does of mountains far above the level of perpetual snow, broad and fertile plains, bathed in intense sunshine, arid wastes, and impenetrable forests. Its natural divisions are the Himalaya, the sub-Himalayan ranges, the plains of the Ganges and the Brahmaputra, the basin of the Indus, the highlands of Hindustan, the Vindhya and Satpura ranges, and the peninsula south of those ranges.

The Himalaya (meaning 'the abode of snow') consists of a chain some 1500 miles in length, in which the links are formed by mountain knots covered with perpetual snow, some of which rise from 20,000 to near 30,000 feet above sea-level, and are the highest yet discovered in the world. It is the dominating factor in the geography of northern India, being the source of the Indus, the Ganges, the Brahmaputra, and of their principal affluents. See HIMALAYA.

The sub-Himalayan ranges run between the chain of the Himalaya and the plains of the Ganges and Indus. They occupy Kashmir, the Simla hill-states, Gurhwal, Kumaon, Nepal, Sikkim, and Bhutan, which, owing to their elevation above the sea (5000 to 9000 feet), have a climate like central Europe in summer and cold as Switzerland in winter, with the vegetation of the temperate zones. These regions are separated from the plain of the Ganges by the submontane tract called Terai, which extends in a long belt, 5 to 25 miles in width, from Hurdwar (where the Ganges issues from the sub-Himalayan ranges) to the Brahmaputra. It is covered with forest, and is the haunt of wild beasts. The soil is very fertile, but malaria has rendered it uninhabitable by man and the domestic animals, at least from April to October. This wilderness is being gradually narrowed or invaded by the progress of drainage and cultivation.

The plains of the Ganges and the Brahmaputra, which include Bengal, Behar, the Doab (meaning the 'Mesopotamia' of the Ganges and Jumna rivers), Oudh, and Rohilkund, form an alluvial flat, terminating in a delta, and extending from the Bay of Bengal to the slight uplands on the Punjab border that form the water-parting between the Ganges and the Indus. Throughout its entire length the Ganges and its numerous tributaries spread out like the veins of a leaf, carrying everywhere their fertilising influence. The population of these fertile and well-cultivated plains is very dense.

The basin of the Indus, in the north-west, is towards the south separated from that of the Ganges by the Aravalli Hills. The Punjab occupies the northern portion. South of the Punjab, and parallel with the river, the great sandy desert of the Indus extends for nearly 500 miles. The valley of the Indus is continued through Sind to the

Arabian Sea. Between the Indus region and the Aravalli Hills lies the Thur desert, an expanse covered with sandhills, 400 miles long and 100 broad. It is only in the neighbourhood of the Indus and some of its tributaries that the surface can be cultivated by means of river-irrigation—although crops of grain may be grown in hollows and narrow valleys after the rains. The horse and camel alone can cross this desert, which is described in Hindu geography as 'the region of death.'

The highlands of Hindustan extend from the Vindhya and Satpura mountains as a base to the border of the Thur desert. They include the tableland of Malwa and Rajputana or Rajasthan, which has an elevation of about 2000 feet above the level of the sea.

The Vindhya and Satpura ranges are two hill-chains, with an elevation from 2500 to 4000 feet, partly though not entirely parallel from east to west, and divided from each other by the valley of the Nerbudda River. They form what may be called the backbone of middle India, or, by another metaphor, a broad wall dividing northern from southern India.

The peninsula south of the Satpura range is in two divisions. The first is the Deccan (q.v.), which name means 'the south.' This area is a central tableland extending from 12° to 21° N. lat., rising from 1500 to 2000 feet above the sea, and enclosed on all sides by mountain-ranges. These ranges are the Satpuras above mentioned, the Eastern Ghâts, somewhat low, facing the Bay of Bengal, and the Western Ghâts, higher and more important, facing the Indian Ocean. Between the Eastern Ghâts and the sea are fertile littoral tracts known to history as the Northern Circars and the Carnatic. Between the Western Ghâts and sea is a similar tract known geographically as the Konkan. As a northern continuation of this tract is Gujarat, with its offshoots the peninsulas of Kathiawar and Cutch. From the low land of the Konkan to the Deccan plateau the mountains rise in a succession of geological formations looking like gigantic terraces. The rivers of the Deccan rise in the Western Ghâts, and, after traversing the tableland, descend to the sea by passages through the Eastern Ghâts. The slope of the country corresponds with the course of the rivers; it has a gradual inclination towards the east. The second division begins technically from the Tungabhadra River, but geographically from the hills south of Chuddanah. It extends right down to Cape Comorin, the apex of the inverted triangle, and includes Madras, Tanjore, Trichinopoly, Tinnevely, and other famous places.

To this summary of natural divisions a brief notice of the mountains and rivers may be added.

The *mountain-system* forms a connected whole. It is separate from the Himalaya and from the Suliman range, which forms a wall between India and Afghanistan. It may best be followed from the southern point, Cape Comorin, northwards, thus: From that point there run upwards two long lines of hills and mountains, one north-easterly, the other north-westerly. The north-easterly line comprises the Eastern Ghâts already mentioned, which become merged in the hilly region on the west of Bengal, and runs up to the neighbourhood of Allahabad, at the junction of the Jumna and the Ganges. This line nowhere exceeds an altitude of 3500 feet above sea-level. The north-westerly line comprises the Travancore and Palni hills, the Nilgiri, the Western Ghâts, the Aravallis, and the Rajasthan hills, up to the neighbourhood of Delhi. This line has at several places considerable altitude, for example in the Nilgiri ('Blue Peak'), 8000 feet and upward; and Mahabaleshwar (near Poona) and Abu in Rajputana, upwards of 4000 feet. These

two lines are as the sides of a triangle, and are joined at the top by the two transverse and parallel ranges of the Vindhya and Satpura already mentioned. Thus the mountain-system, like the external configuration of the country, is in the shape of an inverted triangle.

The *river-system* may be thus epitomised. The Indus in the north-west, with a course of 900 miles after issuing from the Himalayas, drains with its four famous affluents, the Sutlej, the Ravi, the Chenab, and the Jhelum, about 300,000 sq. m., and empties itself into the Arabian Sea. In the north-east the Ganges, with the Jumna and other affluents, and the Brahmaputra and Meghna—all which join in the Bengal delta—drain about 500,000 sq. m. Owing to their virtual amalgamation in Bengal, it is difficult to assign a length to the courses of these rivers, which empty themselves in the Bay of Bengal. The central region—viz. that of the Vindhyas and the Satpura—about 100,000 sq. m.—is drained by the Nerbudda and the Tapti, the former having a course of 800 miles, the latter of 400 miles, and both flowing west into the Gulf of Cambay, a branch of the Arabian Sea. The remaining area (viz. 600,000 sq. m., out of a total of 1,500,000) consists of the Deccan and the peninsula. It is drained by the following rivers: Mahanadi, with a course of 520 miles; Godavari, 898; Kistna, 800; Tungabhadra, 400; Pennar, 350; and Kaveri, 470. There are many other rivers which cannot be particularised here. Among them may be mentioned the Hooghly and the Gumti, Calcutta being situated on the former and Lucknow on the latter; both belong to the Gangetic system.

Geology.—In 1856 a staff of geologists commenced a geological survey of India, which has since then been steadily continued. They have examined an area several times as large as that of Great Britain, and supplied for the districts with which they have dealt an accurate knowledge of the mineral resources.

Professor Medlicott summarises the general result thus. 'Geologically India is divided into three distinct areas: (1) peninsular and (2) extra-peninsular, separated by (3) the Indo-Gangetic plains, formed of the deposits of those great rivers and their tributaries. (1) is a land surface of immense antiquity, all the fossiliferous rocks within it being of aerial or fluvial formation, and the newest of them of Lower Tertiary age. It is principally a *massif* of gneissic rocks, with bands and basins of transition strata of various ages, culminating in the Vindhyan formation, of unaltered and undisturbed strata, yet of undetermined age, being unfossiliferous. Totally separate from the Vindhyan comes the Gondwana formation: near its base the Indian coal-measures on Upper Palæozoic, while the top group, where near the coasts, contains Upper Jurassic marine fossils. A great volcanic formation, known as the Deccan Trap, covers an immense area in Bombay and Central India; the deposits locally found in it contain only fresh-water fossils; in Gujarat it occurs between Eocene and Cretaceous marine strata. Along the outer margin of the plains (2) presents an almost unbroken face of Tertiary rocks, of immense thickness, and more or less intensely disturbed. On the west, associated with Cretaceous strata, they extend to form the uplands of Afghanistan and Persia. On the east, again associated with Upper Secondary beds, they abut against the crystalline rocks of the Malayan axis. On the north they form the sub-Himalayan chain at the base of the central Asian *massif*; the southern ridges of which form the Himalayas; in this position the Tertiary series, except at its very base, is inclusively of fluvial formation, like

the plains, and contains the famous Siwalik mammalian fauna. The outer Himalayan is formed of crystalline and other rocks of uncertain age; but on the north side of the range there is a full succession of Palæozoic and Secondary marine formations. At the north-east angle of the plains the Shillong plateau of crystalline rocks, capped by horizontal Tertiary strata, separating the lower Assam valley from Sylhet in eastern Bengal, is an outlier of the peninsular *massif*. At the north-west angle of the plains, in the Salt Range of the Punjab, there is again a small exposure of the ancient limit of the peninsular *massif*, presenting an outcrop of coastal deposits of Palæozoic age. Besides the Gondwana coal, a light coal occurs sporadically in the Tertiary rocks from Sind to Kashmir, and in upper Assam there are rich coal-measures of about the same age; in both these regions, also, petroleum is more or less abundant. Pure iron ores are abundant throughout the peninsula and in the outer Himalaya; other ores are comparatively scarce, except along the Malayan axis. The diamonds of India and the aluminous gems of Burma are well known.'

In ancient times there were gold-mines in the mountains of the south-western regions, which supplied the metal for the gold coinage which was then almost universal in the country. The most accessible parts of the auriferous strata have been worked out ages ago, and the remnant forms what is known as the Mysore mines. There are other auriferous deposits in parts of the Deccan. Silver has never been discovered in any appreciable quantity within the country; but in the middle ages it was introduced largely from across the Himalayas and used for coinage. In the Shan dependencies of Burma, however, it is extracted from lead ore. Coal is obtained largely in western Bengal, in the Satpura Hills to a considerable extent, and in the Deccan to some extent, and in some other places also. The output in 1921 was 19,303,000 tons, of which 1,144,000 tons were exported, principally to Ceylon, Sumatra, and Straits Settlements. Iron and copper are found and worked in many parts of the country. There are many other mineral products of lesser importance. Diamonds are still found in the central hills, and ruby-mines are worked near the Irawadi. The mineral resources on the whole are inferior in importance to the agricultural. See the *Manual of the Geology of India*, by Medlicott, Blanford, and Ball (revised by Oldham, 1893).

Climate.—In a country extending over 26° of latitude—one extremity of which runs far into the torrid zone, and the other terminates in a range of mountains rising far above the line of perpetual snow—a country embracing lowland plains, elevated plateaus, and alpine regions, the climate must be extremely varied. The whole country has three well-marked seasons—the cool, the hot, and the rainy. This characteristic applies without distinction to all parts of the country; even to the Himalayas, which have otherwise a climate like that of Switzerland. The cool months are November, December, January, and a part of February; the dry hot weather precedes, and the moist hot weather follows the periodical rains. The rainy season falls in the middle of summer; its beginning is earlier or later according to circumstances, its ending is in September. But in Burma it lasts longer; and in the peninsula there is a second rainy season, called the latter rains, during the autumn. The winter is the pleasant period; the spring is generally hot and healthy; the summer depends on the duration of the rains; the autumn is close, malarious, and unhealthy. The rainy season everywhere comes from the same cause—viz. the attraction by the sun of moisture from the ocean in clouds, and their condensation into rain

upon the land. It is called monsoon, probably a corruption of the Persian word for season (see MONSOON). It is the occasional failure of the monsoons that causes the periodical famines to which the country is liable. The central table-land is cool comparatively, but the alternations of heat and cold differ greatly elsewhere. In the north-west there is burning heat with hot winds in summer, and frost at night in winter. In the south the heat is more tempered, but the winter is cool only, and not cold. At Ootacamund, on the Nilgiris, 7200 feet above the level of the sea, the mean annual temperature is 58° F.; at Madras, 83°; Bombay, 84°; Calcutta, 79°; Bangalore, 74°; and at Delhi, 72°. But at places like Delhi, where the heat of summer is tremendous, the average is reduced by the cold in winter. The fall of rain varies greatly in different parts of the country. In the north-eastern and other outlying parts it exceeds 75 inches; at one observatory in north-east Bengal, Cherra Punji, there is a phenomenal fall of 600 inches in the year. In the Deccan, in the upper basins of the Ganges and the Indus, it is 30, and in the lower regions of the Indus less than 15 inches. The remainder of India is placed between the extremes represented by these damp and dry belts, but is, as compared with Europe, an arid country. Hence the necessity of tanks and irrigation canals to supply moisture to the soil, and to obviate the danger of drought and famine. A meteorological department has been established, with 161 observatories, the chief of which are at Calcutta and Bombay. See Henry F. Blanford's *Practical Guide to the Climates and Weather of India* (1889).

Fauna.—The domesticated animals are, first, the cattle—cows, buffaloes, oxen; the last two do the work of agriculture. The bull and cow are sacred animals to Hindus, and by them are never killed for food. The indigenous breeds of horses in India have been improved by the importation of foreign sires. They have never been employed in agriculture. The pony, the donkey, and the mule are largely used. Sheep and goats are abundant. The pig is plentiful, but is despised by the upper and middle classes of the people. The monkeys are tame and are held sacred. The wild animals include the tiger, panther, cheetah, boar, bear, bison, elephant, and rhinoceros. The crocodile and alligator infest most of the rivers. Deer of all sorts abound everywhere, and mainly supply sustenance to the carnivorous animals. The lion, the hyæna, the lynx, and the wolf are unimportant. The elephant is used only for purposes of war or of state, both by the government and by the native nobility. The ibex and the ovis-ammon (the wild goat and the wild sheep) are found only in the highest parts of the Himalayas. Poisonous snakes abound, the worst being the cobra da capello (the black-hooded): many thousands of the natives die from snake-bite in the year. The government offer rewards, and many thousands of animals, including snakes, are destroyed. The area supporting these animals has shrunk during the present century from the spread of cultivation, and is still shrinking. Destructive visitations of locusts happen occasionally. The birds are, of course, infinitely various; but several of the most beautiful or remarkable species are wanting. The eagle is found only in the Himalayas, so is the pheasant. The partridge is seen in all the plains, and in some places the quail is abundant. The snipe is found in the marshy land; waterfowl swarm in some localities, and flights of wild geese sweep through the air. Vultures and other birds serve as scavengers. The crow is common everywhere, but not the raven.

At the seaport towns the supply of fish for

European consumption is excellent, and fish-curing is largely practised by the people. Inland the fishing in the mountain-streams is good, but in the rivers of the champaign the fish, though abundant in quantity, are not esteemed for quality. See *Fauna of British India*, ed. Sir Arthur Shipley.

Flora.—Nearly half of the country is tropical, though none of it is equatorial, and a part is not only temperate, but cold; accordingly the vegetation varies greatly. As compared with equatorial regions, the country has tropical products plentiful and good, but not first-rate, such as tobacco, sugar, ginger, and spices of all sorts. Rice has from time immemorial been a staple. Maize and millet are articles of food where rice is less easily got. Jute is an important fibre. Oilseeds are largely exported. The cultivation of wheat has greatly developed for exportation since the era of cheap prices. Tea is grown largely under European supervision in the Eastern Himalayas, and already surpasses the China teas. Coffee is grown in the south, but with chequered success. Among the dyes, indigo and lac (red) are noteworthy. European flowers of all sorts are cultivated nowadays. The indigenous flowers are not rich, the water-lilies being the best; the flowering shrubs are very fine, however. Of trees in the plains near the coasts the palm order with its several varieties strikes the observer. Inland the mango fruit-tree and the orange, the umbrageous banyan, the sacred peepul, and the bamboo are features in the landscape. In the hills the teak and other useful timber trees are obtained. In the Himalayas are the cedar, the pine, the fir, the juniper.

The primeval forests which covered the country have long been restricted to the hill and mountain system already described. But further, in this country, as in many other countries, the hills have been deforested by reckless destruction during many generations, to the injury of the climate and of that water-supply on which so much depends. Conservation of forests was not attempted under native rule, nor under British rule until the middle of the 19th century. Since that time, however, a forestry department has been set up as a branch of the administration in every province, with European officers trained in Europe. For the whole country, the forests under supervision amount to 250,000 sq. m., of which 100,000 are under complete conservancy. Besides augmenting the national resources, the forestry is profitable, and yields a net revenue yearly of more than a million sterling.

The agricultural statistics show that less than one-half of the whole country is cultivated or grazed. Of the remainder a portion is available for cultivation; the rest is uncultivable, consisting of stiff hillsides, desert, river-beds, &c.

II. THE PEOPLE.

Population.—This has since the middle of the 19th century been ascertained by census. The decennial census of 1881 showed 253 millions of souls for the whole country, including the British territories and the native states, and an increase of 13 millions over the preceding census. This total was exclusive of the population of the Kashmir state, which really belonged to the country, and of Upper Burma, subsequently annexed. With Kashmir and all Burma the population at the census of 1911 was 315,156,396, an increase of 20,791,340 over the figures for 1901; and this total excludes Nepál, Bhutan, and French and Portuguese territory. The 1921 census shows a total population of 318,942,480. But though populous, the country is not as a whole densely peopled, the average of inhabitants to the square mile being 226 for the British provinces, 160 for the

Indian states, and 176 for the whole country. The hill and mountain system, indeed, shows a sparse population; but the plains of the Ganges and the Brahmaputra, and the coast districts and the southern peninsula, are densely peopled. The Gangetic plain generally has an average of 400 to the square mile; and some parts of it, near Benares and Patna, show an average actually double the above, and a density which is quite excessive. Of the 319 millions not more than 32½ were urban, the rest being rural. Thus the vast majority of the people live in the country, and most of these are agricultural or pastoral. In most provinces the returns show an excess in the number of males over that of females.

The populations of the three presidency cities at the census of 1921 were: Calcutta, 1,327,547; Bombay, 1,175,914; Madras, 526,911. Below these there are thirty-one towns with more than 100,000 inhabitants each, and below these again fifty-five with more than 50,000 each.

Ethnology and Language.—The languages of the present day as well as those spoken in former ages, as far as these are known to us, belong to four different stocks—viz. the Aryan, Dravidian, Kolarian, and Tibeto-Burman stocks. In point of chronological order the Kolarians appear to have been the first settlers, and all indications point to their having originally entered India from the north-east, and having thence spread westwards over the northern plains. As regards the tribes speaking Tibeto-Burman dialects, they are confined to the skirts of the Himalayan range; thus forming, as it were, the southern edge of the wide Tibetan speech-field, having probably penetrated at various times, from the plateau of Tibet, through the numerous passes of the Himalayas. Eastwards, again, these dialects stretch, in a more or less continuous chain, until they merge in the compact body of Burman speech. But whilst a separate linguistic development makes it necessary to treat the Kolarian and Tibeto-Burman languages as two distinct groups, it is yet highly probable that they were ultimately derived from the same Mongol stock. After a time the Kolarian settlers would seem to have been disturbed in their possession of the northern plains by the inroads of Dravidian tribes. These, having gained entrance into India through the north-western passes, seem to have pushed forward, driving the Kolarians into the mountainous districts which border the Gangetic plain in the south, and ultimately to have forced their way through them, and poured themselves in a mighty stream into the southern peninsula. Whether in so doing they were already urged onward by tribes of another race following in their wake we do not know; certain it is, however, that at some time or other subsequent to the immigration of the Dravidians—probably more than 4000 years ago—people of the Aryan stock must have entered the ‘land of the five rivers’ (Punjab) either through those same passes of the Suliman range, the command of which has so often decided the fate of India, or by a more northerly and yet more rugged route, across the Hindu-Kush, and by way of the Pamir plateau and the highland valley of Kashmir. In favour of this latter alternative it has been urged that there are to this day settled, to the north of Kashmir and Kabul, several tribes of the Aryan stock, such as the Dards and the Siah-Posh Kafirs, whose vernacular dialects are of so archaic a character as to have suggested the idea that these tribes may perhaps be the direct descendants of some remnants of the primitive (Indo-Iranic) Aryans which had remained behind in the old homes when the great body of their brethren took their departure in quest of more favoured abodes. However, our knowledge

of these waifs and strays of the Aryan stock is still very imperfect; and they may after all turn out to be mere detached dialects of either the Indic or the Iranian branch of Aryan speech. Between these two divisions no sharp line of demarcation can indeed be drawn; but the languages of the countries west of the Indus—viz. the Pushtu (or Pakhtu) of the Afghans, and the Baluchi, one of the two principal languages of Beluchistan—form intermediate links, being by most scholars included in the Iranian group, whilst others would rather refer them to the Indian division.

(1) *Indo-Aryan Group.*—The earliest accessible form of Aryan speech in India is the *Vedic*, especially the language of the sacred hymns of the *Rigveda* which represent the Aryan tribes as settled in the Punjab. Even at that early period dialectic varieties seem already to have existed to some extent among different tribes. In the course of the later Vedic ages the Aryan language extended its sway eastward over nearly the whole of northern India. During this process foreign ethnic elements were doubtless largely absorbed by the Aryan community, and the greater or less proportion of such admixtures, coupled with independent political formations, could not fail ere long to produce different dialects of marked individuality. Meanwhile, the exegesis of the sacred hymns, already largely unintelligible at the time when they were first collected, and the consequent close cultivation of grammatical and phonetic studies, resulted in the grammatical fixation of the literary language (hence called *Sanskrit*—i.e. ‘completely or correctly formed, polished’), probably about the 6th century B.C. Henceforth the divorce between the literary idiom and the popular dialects was complete. The existence of such dialects at that time is amply attested by the fact that Gautama S’akyamuni (or Buddha, ‘the awakened,’ as he subsequently called himself), in preaching his new gospel of salvation through individual righteousness, made use of the Magadhi, commonly called *Pāli*, the local dialect of his native Magadha (Behar), which accordingly became the sacred language of Buddhist literature; but being as such a grammatically fixed idiom, like the Sanskrit, it became gradually estranged from the vernacular with which it had originally been identical. The canonical books of the Buddhists were settled at a council held in the reign of the Emperor As’oka about 250 B.C., but they were not committed to writing till about 80 B.C., so that the state of their language is attested for that period at latest. The same Emperor As’oka has, however, left us authentic dialectic documents of his own time—viz. the famous rock inscriptions, containing religious edicts, and scattered over the area of northern India from the vicinity of Peshawar on the north-west frontier, and Gīrnar in Gujarat, to Cuttack on the eastern coast. Similar in its origin to the *Pāli*, another local dialect, the *Mahārāshtrī*, or language of the province of Mahārāshtra (the present Mahratta country), became the religious dialect of another large sect, the Jains, which seems to go back to about the same time as the origin of Buddhism. Moreover, several popular dialects were early employed for literary purposes by Indian dramatists. While the use of Sanskrit in dramatic literature is confined to male characters of the higher classes, women and inferior male characters are invariably made to speak various local dialects. These dialects, called *Prākṛits*—i.e. either ‘vulgar’ or ‘derived (from the Sanskrit)’—may be looked upon as the forerunners of the modern vernaculars of northern India. Though the oldest existing plays can hardly be placed earlier than the 6th century of our era, the actual use of the *Prākṛits*, as popularly spoken.

dialects, may go back some centuries before that time. The principal *Neo-Aryan* languages of India are (1) *Bengali*; (2) *Urīyā* (of Orissa); (3) *Hindī* (of the Upper Provinces), with the closely allied *Panjābī* and *Nepālī* (the language of the Goorkhas, the ruling class of Nepal); (4) *Sindhī* (on the lower Indus); (5) *Kashmirī*; (6) *Marāṭhī*; (7) *Gujarātī*—which Beames (*Comparative Grammar of the Modern Aryan Languages of India*), however, takes to be a mere dialect of Hindi. To these may be added (8) *Assamese*, formerly considered a dialect of Bengali; (9) *Brāhūī*, one of the two languages spoken in Beluchistan, which at one time was thought to be Dravidian, whilst some scholars would even now refer it to the Kolarian group; and (10) *Sinhalese*, the language of the southern half (perhaps at one time of the whole) of the island of Ceylon, doubtless imported from northern India, in the early centuries B.C., by Buddhist immigrants; with its literary dialect called *Elu*, and the dialect of the Aryanised aboriginal Veddas.

Many of these languages show a considerable number of dialectic varieties, especially the Hindi, by far the most important of all, of which as many as fifty-nine dialects are enumerated by Cust (*Modern Languages of the East Indies*). Not a few of these dialects are, however, of a very mixed character, owing to their being spoken by Aryanised tribes of one of the three other groups, and consequently showing a more or less strong non-Aryan element. A peculiar and important form (for it can scarcely be called a distinct dialect) of Hindi is *Urdu* or *Hindustānī*, which, being Hindi, with a more or less considerable admixture of Persian (and Arabic) words, and written in the Persian character, originated, after the Mohammedan conquest, through the official intercourse of the Persian-speaking rulers and their Hindu subjects—much as in English the original Teutonic groundwork has been overlaid by a thick layer of Romance and Latin vocables and formative elements—and has developed into a kind of *lingua franca* for the whole of India; a southern variety of it being called *Dakhnī* or *Dekhnī*. In point of the antiquity of its literary documents, Sinhalese stands pre-eminent among Neo-Aryan languages; its development from, or by the side of, Pāli being well authenticated by *Elu* works going back to the 5th century of our era, and by inscriptions of very early date. Next to it comes Hindi, commencing, about 1200 A.D., with the *Prithirāj Rāsau*, a heroic poem by Chand Bardāi, composed in an archaic form of Hindi which Trumpp proposes to call 'Old Hindui'; whilst the term 'Hindui' is applied by him to a somewhat more modern form, represented by the writings of the religious reformer Kabir (c. 1450 A.D.), the sacred books of the Sikhs (the *Granth*), and Tulsi Dās's translation of the Sanskrit epic *Rāmāyana*. In Marāṭhī the oldest existing work, a paraphrase of the Sanskrit philosophical poem *Bhagavadgītā*, claims to have been written in 1290 A.D.; whilst Bengali literature commences with the religious writings of the Vaishnava reformer Chaitanya, a contemporary of Luther. None of the other languages possess any literature above two or three centuries old.

(2) *Dravidian Group*.—The extension of the Brahmanical civilisation and literature has introduced into these languages, as into those of the other stocks, a very considerable element of Sanskrit words; whilst their grammatical structure has, on the whole, remained intact. As regards the ultimate affinities of this stock, Dr Caldwell, in his *Comparative Grammar of the Dravidian Languages*, has shown that Dravidian speech, in its formative features, betrays a 'family likeness' to the Seythic (Finnic-Tataric) stock; whilst he

also detects in it certain analogies, though of a rather indefinite and remote character, to Aryan speech. The people speaking Dravidian languages occupy a compact area extending over the whole of the southern part of the peninsula, with one or two *enclaves* in the Aryan territory. Dravidian scholars recognise twelve distinct languages, only four of which, also the most important in regard to population, have developed anything worthy of the name of a literature—viz. (1) *Tamil*, occupying the south-eastern; (2) *Telugu*, the north-eastern; (3) *Kanarese* (or *Kannada*, i.e. Karnataka), the north-western; and (4) *Malayālam*, the south-western portion of the Dravidian area. The remaining members of the family are (5) *Tulu*, between the two preceding ones, on the Malabar coast; (6) *Kodagu*, the language of Coorg, adjoining the last named, inland; (7) *Tuda* and (8) *Kotu*, both spoken by tribes of the Nilgiri hills; (9) *Gond*, in Central India; (10) *Khond* and (11) *Orāon*, west and north-west of Orissa; and (12) *Rājmahāl*, or *Māler*, the language of a tribe of the Rājmahāl hills in Bengal. Tamil, which has also extended its sway over the northern half of Ceylon, may boast of a rich and varied literature; its oldest works—the *Chintāmani*, an epic poem of 15,000 lines, and the *Kural*, a collection of ethical stanzas, both of them by Jain poets—probably dating back to the 10th century, if not earlier. In the sister languages, Nannaya's Telugu translation of the epic *Mahābhārata* and Kesava's Kanarese grammar probably belong to the 12th century; whilst Malayālam, originally a mere dialect of Tamil, commences with the heroic poem *Kāmācharita*, of uncertain date, but probably a century or two later than those works.

(3) *Munda Group*.—This term is preferred for a group which has also been called Kolarian (from the Kols). The people speaking these languages, settled chiefly in the jungle and mountainous tracts of the Central Provinces, are computed to number about two million, though many tribes, such as the Bhils, who have adopted other languages, especially Hindi, ethnologically doubtless belong to this group. Munda speech possesses a very complete suffixal system of inflection, its conjugational system being especially developed. Some of the chief points in which it differs from Dravidian speech are that it has a dual number for nouns, and that it lacks a negative form of the verb. Our knowledge of most of these languages is, however, still sadly defective. Brandreth proposes to include nine different languages under this group, to which Cust adds a tenth; but this scheme is so far only provisional. The best-known member of this family is the *Santalī*—spoken by a vigorous tribe inhabiting the so-called Santal Parganas (and adjoining districts) along the western frontier of Lower Bengal—of which we have a good grammar by Skreksrud (1873). The only other language of this group the grammar of which has been at all adequately treated is the *Mundari*, spoken by Mundas, Bhumijs, and Larka Kols; whilst of others, which are probably destined to die out before long, we have as yet only scanty vocabularies.

(4) *Tibeto-Burman Group*.—This field has also as yet been very imperfectly surveyed, most of its languages lying either wholly beyond the Indian frontier, or only just projecting into the British territory. They share the general agglutinative character of the only two literary languages of this family, the Tibetan and Burmese, whilst in them the tone of the voice also plays generally an important part in the meaning of words, though not to the same extent as in monosyllabic languages. Brandreth proposes to arrange these border-languages in nineteen different classes, which Cust re-

duces to a few geographical groups—viz. the Nepál, Sikkim, Assam, Manipur-Chittagong, and Trans-Himalayan groups—the last-named group consisting of the southern offshoots of the Tibetan branch of Tibeto-Burman speech.

A curious cluster of dialects, which seems to be independent of any of the four groups of Indian speech hitherto mentioned, is found in the Khási hills, in the province of Assam. There is a good *Khási* grammar by Pryse. This language, in which five or six dialects are distinguished, is of the monosyllabic order; but its exact relationship has not yet been determined.

The word Hindu has been used in various senses. In truth it means all those who profess the Hindu or Brahmanic faith, which, however, consists of many sects. This vast community of over 216 millions of souls is divided into several Castes (q.v.), high and low. The high castes are mainly Aryan, the lower castes partly Aryan and partly Dravidian or aboriginal. A person must be born into the high castes, and cannot enter them by conversion. If a person, as for instance an aboriginal, be converted, he can enter the lower castes only. The sections of Hindu community thus summarised differ not only in nationality and language in different provinces, but in customs and dress. Their languages are to be counted by scores.

The Mohammedan (or, strictly, Muhammedan) population, on the other hand (about 68 millions), in all parts of India affect the same customs, and generally speak one language—Hindustáni or Urdú. It is the one chiefly known to Europeans. It is the vernacular in the towns alone, and those, too, of the north-west only. In these provinces, also, it is the official language. It is, however, hardly known to the Mohammedans of eastern Bengal, who speak Bengali. Persian and Arabic are more or less known as classical languages to the Mohammedans of India, but are not spoken. The language of the courts of justice is everywhere the language of the province.

The aboriginal hill-tribes have caused trouble on the Assam frontier at various times, especially those on the north-east frontier near Assam. The hill-tribes of the Dravidian race also are in a primitive state socially. Of these the most important are the Bhils and Gonds, who are found in the Vindhya and Satpura regions, the Khonds and Kols, who inhabit the Eastern Gháts, and the Sontals on the hill-country west of Bengal. The Bhils were wont to live by plunder, and used to burst out of their jungles, committing many outrages; but in 1825, after various methods of subduing them had been unsuccessfully tried by the British government, it was resolved to tempt them into military service, with good results. The Khonds and Kols, driven into the jungles and mountains of Central India by the advance of the Aryan race from the north-west, have preserved the grim religion that prevailed in the country before Hinduism was heard of. That religion may be briefly characterised as Devil-worship, with efforts to propitiate the malignant deities by human sacrifice, principally of children. Successful efforts have been made by the British government to suppress these practices. As a tribe the Gonds are the strongest; they adopted parts of both Hindu and Mohammedan culture, founded a rude dynasty, and signalled their rule by works of material improvement. For more than a century past they have relapsed into their pristine condition. It is from among these aboriginal tribes, numbering in all perhaps ten millions, that proselytes to Hinduism are obtained.

National Character.—To the inhabitants of India, who, although generally a mixed race of Dravidian

and Aryan origin, now form many distinct nations, no general statement can apply. The acute but unwarlike inhabitants of the Gangetic delta are quite unlike the less intellectual but sturdier races of the upper basins of the Ganges and the Indus—i.e. the United Provinces and the Punjab. These latter again are dissimilar from the high-bred and chivalrous race of Rajasthan or Rajputana, and the hardy though humble Mahratta of the Western Gháts. Still further varieties are found in the half-warlike and partly refined races of the eastern coast and southern peninsula, mixed up with races of lesser spirit and culture. The races who in this generation are believed to have political aspirations are the Sikhs of the Punjab—the Sikh faith being really an offshoot of Hinduism—the Goorkhas of Nepál, and the Mahrattas of the Western Gháts; and perhaps some sections of Mohammedans, who might be aided by Arabs immigrating from Arabia. The Brahmins everywhere, to whatever nationality they may belong, or whatever language they may speak, have a homogeneous character, imbued with a lofty pride transmitted through long generations.

The Mohammedans of central Asiatic descent are strict adherents of their faith, and sometimes fanatical. But those who, like the inhabitants of eastern Bengal and of parts of the Punjab, are merely Hindus or aborigines made Mohammedans by conversion, are of course less orthodox. Their religion is a mixture of the doctrines of the Koran with the local idolatry. The Parsees, a mercantile and educated class, seated at Bombay and along the west coast of India, are the descendants of the fugitive fire-worshippers of Persia. See PARSEES.

The national character cannot be portrayed from this congeries of nationalities, yet some characteristics can be set forth as generally prevalent: for the upper and middle classes, domestic affection, munificence, tenacious adherence to custom, veneration with awe leading to superstition, love of external nature, an inclination for abstract meditation, mental acuteness and subtlety, litigiousness, shrewdness of observation; for the humbler classes, temperance, patience, docility, charitableness to the indigent, endurance, fortitude under disaster, and industry. 'Dharm' to the Hindu, and 'Dín' to the Mohammedan, means virtue under a religious sanction. In justice to the women, it must be said that, despite their subjection and seclusion, they have shown courageous fortitude in times of danger and charitable munificence when endowed with means. The suttee 'widow-burning' evinced supreme resolution. Predatory and pugnacious instincts, hereditary in some classes, are partly subdued by the *pax romana* of British rule.

Politically the leading factor was this, that the congeries of nationalities, despite community of faith, had no idea of national union or of self-organisation. This rendered them comparatively easy of government by a foreign power possessed of governing capacity. There is now a growing recognition of nationality, manifested in various ways, of 'India's place in the Empire,' and the need for unity.

Physical Qualities.—These vary together with race and climate. The stature is often tall in the north, and short in the south—very much as in Europe. Strength does not depend on height, of course. The Nepálese are short, so are the Mahrattas; both are strong. As a rule, strength with courage is found more in the north than in the south, but least perhaps in the Gangetic delta. Bengal is the only large province that furnishes no recruits to the army. Physical endurance, the power of making protracted bodily exertion with but scanty sustenance, is perceptible everywhere;

in some places it is extraordinary, and rarely to be equalled in any country. An Indian has hardly half the strength or nervous force of a European, perhaps not more than one-third; his work would be in the same proportion. In consequence of this and of the cheapness of living, his wages are not more than one-sixth of the British rate. A proposition of this sort cannot be stated accurately or definitely, but some such truth as this lies at the basis of the political economy of the country.

RELIGION.—Hinduism or Brahmanism is the religion of the great majority of the people, and Mohammedanism comes next. Of the 318,942,480 inhabitants of India, British and feudatory, in 1921, 216,734,586 were Hindus, 68,735,233 Mohammedans, 9,774,611 aboriginal pagans, 11,571,268 Buddhists (almost all in Burma), 1,178,596 Jains, 101,778 Parsees (chiefly in Bombay), 21,778 Jews. Excluding Indian states there were in Bengal 25,210,802 Mohammedans to 20,206,859 Hindus; in the Punjab, 11,444,321 to 6,579,260 Hindus and 2,294,207 Sikhs; in Bihar and Orissa, 3,690,182 to 28,166,459 Hindus. The Christians in British India number 3,027,881, those in Indian states and agencies 1,726,183. Buddhism at one period prevailed very generally throughout India; it is now practically confined to Bengal, Sikkim, and Burma. See **BUDDHISM, JAINS, MOHAMMED, PARSEES, SIKHS.**

Hinduism.—The first to be considered is that variety of creeds which is derived from Brahmanic sources, and known as the Hindu religion, or Hinduism. The following summary of the origin and development of Hinduism is from Goldsticker's essay (*Literary Remains*, 1879), originally written for the first edition of this work.

Hinduism may be divided into three periods, the Vedic, Epic, and Purānic, as our knowledge of the first is derived from the sacred books called the *Veda*, of the second from the epic poems the *Rāmāyana* and the *Mahābhārata*, of the third from the mythological works known under the name of *Purānas* and *Tantras*. Writers on this subject have marked the beginnings of certain divisions of Vedic works with 1200, 1000, 800, and 600 years B.C. The question of Hindu chronology will be more particularly considered in the article **VEDA**. Probably the latest writings of the Vedic class are not more recent than the 2d century B.C. Uncertainty hangs over the period at which the two great epic poems were composed, although there is reason to surmise that the lower limits of that period are not far from the beginning of the Christian era. The Purānic period, on the other hand, all scholars are agreed to regard as corresponding with part of our medieval history.

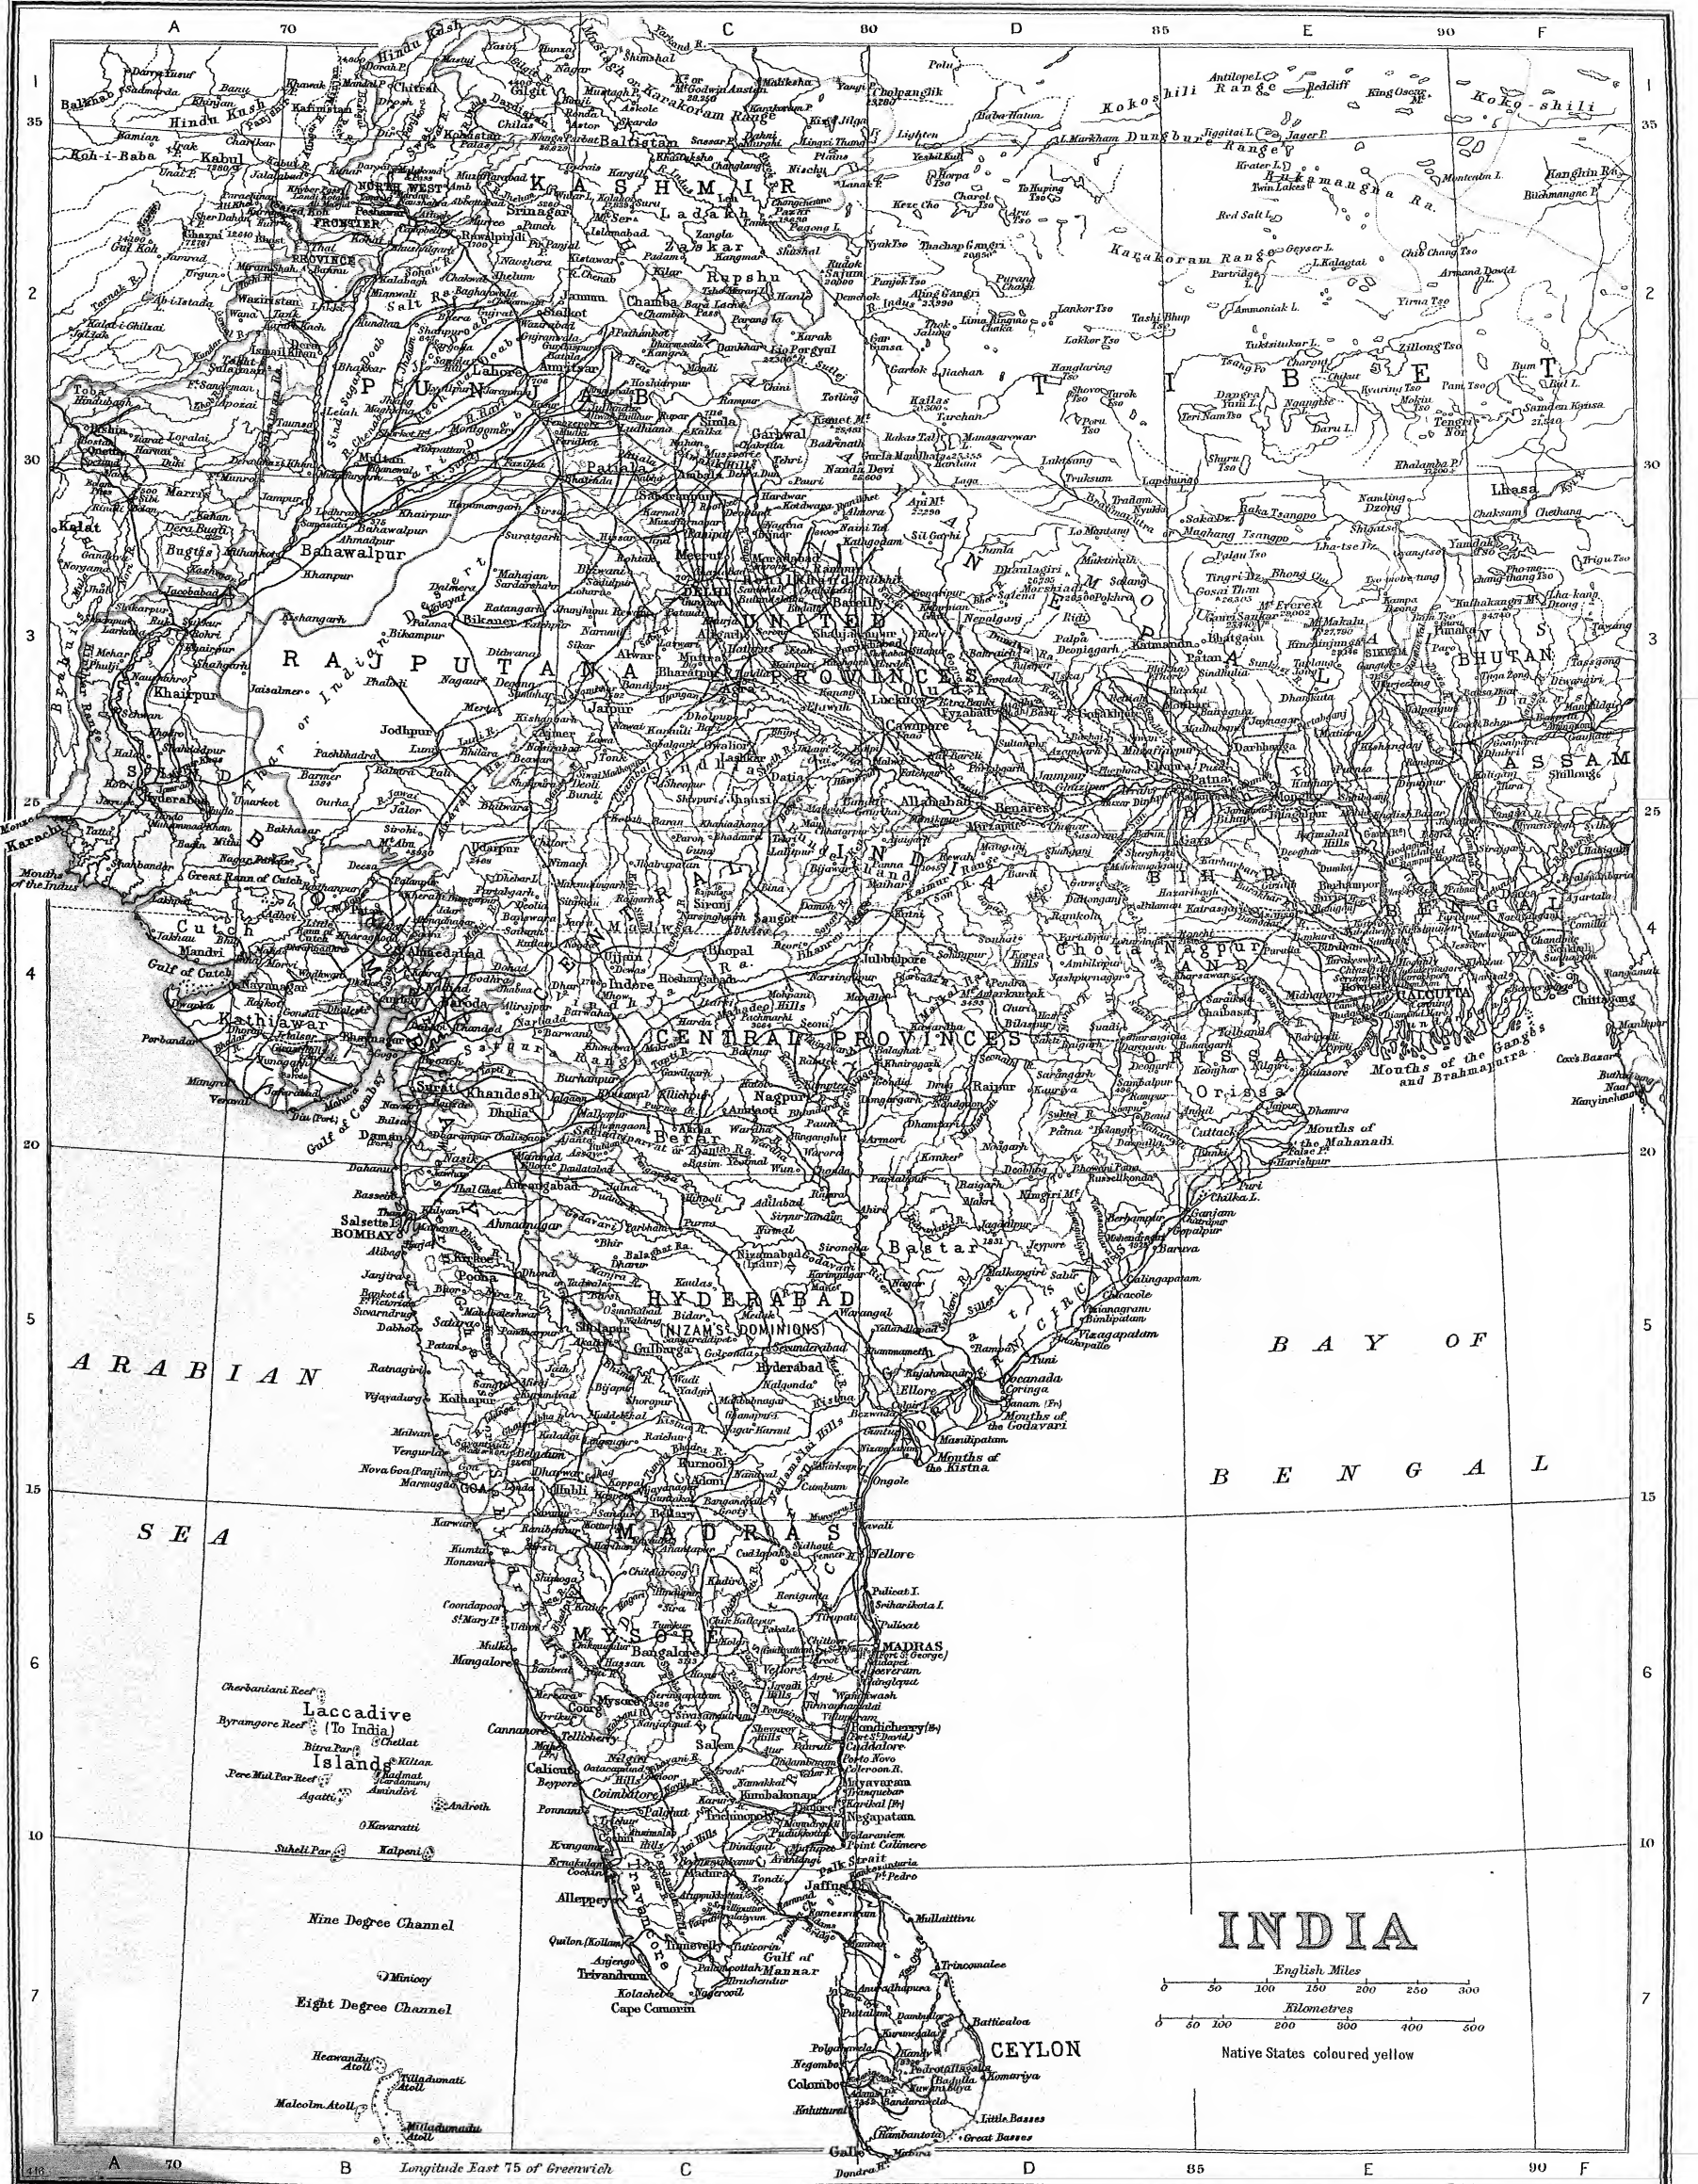

The Vedas.—If the *Rig-Veda*—the oldest of the Vedas, and probably the oldest literary document in existence—coincided with the beginning of Hindu civilisation, the popular creed of the Hindus, as depicted in some of its hymns, would reveal the original creed not only of this nation, but also of humanity itself. The Hindus, as depicted in these hymns, are far advanced beyond the starting-point of human society. Indeed they may be ranked among these communities already experienced in arts, defending their homes and property in organised warfare, acquainted even with many vices which only occur in an advanced condition of artificial life (see **VEDA**). Yet the ideas expressed in the greatest number of the *Rig-Veda* hymns are neither emanating from an artificial imagination nor largely affected by philosophy. The Hindu of these hymns is engrossed by the might of the elements. The powers which turn his awe into pious subjection are: *Agni*, the fire of the sun and lightning; *Indra*, the bright, cloudless firmament; the *Moruts*, or winds; *Sūrya*, the sun; *Ushas*, the dawn; and nature in general. He

invokes them, not as representatives of a superior being, before whom the human soul professes its humility, but because he wants their assistance against enemies—because he wishes to obtain from them rain, food, cattle, health, and other worldly goods. He seeks them, not for his spiritual, but for his material welfare. Sin and evil, indeed, are often adverted to, and the gods are praised because they destroy sinners and evildoers. But these words are not to be associated with our notions of wrong. A sinner, in these hymns, is a man who fails to address praises to those elemental deities, or to gratify them with the oblations they receive at the hands of the believer. He is the foe, the robber, the demon—in short, the borderer infesting the territory of the 'pious' man, who, in his turn, injures and kills the other. On the whole these hymns, so far from reflecting unfavourably on the internal condition of the Hindu community, seem, on the contrary, to bespeak the union and brotherhood which existed among its members.

The worship of the elementary beings was originally simple and harmless. Most of the *Rig-Veda* hymns mention but one sort of offering made to these gods. It consists of the juice of the *Soma* (q.v.) or moon-plant, which, expressed and fermented, was an exhilarating and inebriating beverage. There is a class of hymns, however, to be found in the *Rig-Veda* in which the instinctive utterance of feeling makes room for the language of speculation; and the mysteries of nature being more keenly felt, the circle of beings which overawe the popular mind becomes enlarged. Thus, the objects by which *Indra*, *Agni*, and the other deities are propitiated, become gods themselves; *Soma* is invoked as the bestower of all worldly boons. The animal sacrifice is added to the original rites; and the horse of the sacrifice especially is invoked by the worshipper.

Mystical language then shows that religion was endeavouring to penetrate into the mysteries of creation. This longing is expressed in other hymns, which mark the beginning of the *philosophical creed of the Vedic period*. The following extract will illustrate the nature of this third class of hymns, as they occur in the oldest *Veda*: 'Then there was no entity or non-entity; no world, or sky, or aught above it; nor water deep or dangerous. Death was not, nor was there immortality, nor distinction of day or night. But THAT breathed without affiliation, single with her who is within him. Other than he, nothing existed which since has been. . . . Who knows exactly, and who shall in this world declare, whence and why this creation took place? The gods are subsequent to the production of this world; then who can know whence it proceeded, or whence this varied world arose, or whether it uphold itself or not? He who in the highest heaven is the ruler of this universe, does indeed know; but not another one can possess this knowledge.'

As soon as the problem implied by passages, like these was raised, Hinduism must have ceased to be the pure worship of the elementary powers. Henceforward, therefore, we see it struggling to reconcile the latter with the idea of one supreme being. The first of these efforts is shown in that portion of the Vedas called *Brahmanas*, the second in the writings termed *Upanishad*. In the *Brahmanas* the mystical allegories are reduced to a systematic form. Epithets given by the *Rig-Veda* poets to the elementary gods are spun out into legends. A ponderous ritual, founded on those legends, is brought into a system which requires a class of priests. However much this ritual betrays the gradual development of the institution of castes (unknown to the hymns of the *Rig-Veda*), there are still two features in them

which mark a progress of the religious mind of the ancient Hindus. While the poets of the Rig-Veda are chiefly concerned in glorifying the visible manifestations of the elementary gods, in the Bráhmanas their ethical qualities are put forward for imitation and praise. Truth and untruth, right and wrong—in the moral sense which these words imply—are often emphasised in the description of the battles fought between gods and demons. A second feature is the tendency in these Bráhmanas to determine the rank of the gods, and to give prominence to one special god amongst the rest; whereas in the old Vedic poetry, though there may be a predilection to bestow more praise on some gods than on others, yet there is no intention to raise any of them to a supreme rank. Thus, in some Bráhmanas *Indra*, the god of the firmament, is endowed with the dignity of a ruler of the gods; in others the sun receives the attributes of superiority.

The Upanishads.—An answer to the question regarding the Almighty is attempted by the 'mysterious doctrine,' as laid down in the writings known under the name of *Upanishads*. Their object is to explain, not only the process of creation, but also the nature of a supreme being, and its relation to the human soul. In the Upanishads the deities of the Vedic hymns become symbols to assist the mind in an attempt to understand the true nature of one absolute entity, and the manner in which it manifests itself in its worldly form. The human soul itself is of the same nature as this supreme or great soul: its ultimate destination is that of becoming reunited with the supreme soul, and the means of attaining that end is not the performance of sacrificial rites, but the comprehension of its own self and of the great soul. Thus the Upanishads became the basis of a comparatively enlightened faith. They contain the germs whence the three great systems of Hindu philosophy arose. They advance sufficiently far to express belief in a supreme being, but acknowledge the inability of the human mind to comprehend its essence. See VEDA.

The Epics and the Philosophy.—The Epic period of Hinduism is marked by a development of the two creeds, the general features of which have now been traced in the Vedic writings. The popular creed strives to find a centre round which to group its imaginary gods, whereas the philosophical creed finds its expression in the groundworks of the *Sāṅkhya*, *Nyāya*, and *Vedānta* systems of philosophy. In the former we find two gods in particular who are rising to the highest rank, Vishnu and Siva; for as to Brahmá (the masculine form of Brahman), though he was looked upon now and then as superior to both, he gradually disappears, and becomes merged into the philosophical Brahma (the neuter form of the same word), which is a further evolution of the great soul of the Upanishads. In the epos *Rámáyana*, the superiority of Vishnu is admitted without dispute; in the great epos, the *Mahábhārata*, however—which, unlike the former epos, is the product of successive ages—there is an apparent rivalry between the claims of Vishnu and Siva to occupy the highest rank in the pantheon. Already there is a predilection during this Epic period for the supremacy of Vishnu; and the policy of incorporating rather than combating antagonistic creeds led more to a quiet admission than to a warm support of Siva's claims to the highest rank. One remarkable myth illustrates the altered position of the gods during the Epic period. In the Vedic hymns the immortality of the gods is never matter of doubt. The offerings they receive may add to their comfort and strength, but are not indispensable for their existence. It is, on the contrary, the pious sacrificer himself who, through his offerings,

secures to himself long life and immortality afterwards. And the same notion prevails throughout the oldest Bráhmanas. It is only in the latest work of this class, and more especially in the Epic poems, that we find the inferior gods as mortal in the beginning, and as becoming immortal through exterior agency. In the *Satapatha-Bráhmana* the juice of the Soma plant, offered by the worshipper, or at another time clarified butter, or even animal sacrifices, impart to them this immortality. At the Epic period Vishnu teaches them how to obtain the *Amrita*, or beverage of immortality, without which they would go to destruction.

The philosophical creed of this period develops the notion that the union of the individual soul with the supreme spirit may be aided by penances, such as peculiar modes of breathing, particular postures, protracted fasting, and the like; in short, by those practices which are systematised by the Yoga doctrine. The most remarkable Epic work which inculcates this doctrine is the celebrated poem *Bhagavadgītā*, which S'ankara, the great philosopher, declared to be founded on the Yoga belief. The doctrine of the reunion of the individual soul with the supreme soul was necessarily founded on the assumption that the former must have become free from all guilt affecting its purity before it can be merged into the source whence it proceeded. And, since one human life is apparently too short for enabling the soul to attain thereto, the Hindu mind concluded that the soul, after the death of its temporary owner, had to be born again, in order to complete the work it had left undone in its previous existence. This is the Hindu doctrine of *metempsychosis*. The beginning of this doctrine may be discovered in some of the oldest Upanishads, but its fantastical development belongs to the Epic time.

The Purānas and the Tantras.—The Purānic period of Hinduism is that of its decline, so far as the popular creed is concerned. Its pantheon is nominally the same as that of the Epic period. Brahmá, Vishnu, and Siva remain still at the head of its imaginary gods. But whereas the Epic time is generally characterised by a friendly harmony between the higher occupants of the divine spheres, the Purānic period shows discord and destruction of the original ideas whence the Epic gods arose. Brahmá is withdrawn from the popular adoration, leaving Vishnu and Siva to fight their battles in the minds of their worshippers for the highest rank. The divine element which still distinguishes these gods in the *Rámáyana* and *Mahábhārata* is now more and more mixed up with worldly concerns and intersected with historical events, disfigured in their turn to suit individual interests. Of the ideas implied by the Vedic rites scarcely a trace is visible in the Purānas and Tantras, which are the textbooks of this creed. Some Purānas, it is true—e.g. the *Bhāgavata*—make in some sense an exception to this aberration from original Hinduism; but they are a compromise between the popular creed and the Vedānta creed, which latter remains the faith of the educated and intelligent. They do not affect the worship of the masses as practised by the various sects, whether harmless, as with the worshippers of Vishnu, or offensive, as with the adorers of Siva and his wife Dúrga. It is this popular creed which, with further deteriorations caused by the lapse of centuries, is still the main religion of the masses in India. See PURĀNA and SANSKRIT.

The philosophical creed of this period, which is still preserved by the educated classes, is derived from the Vedānta philosophy. It is based on the belief of one supreme being, who is invested with all the perfection conceivable by the human mind. But the nature of that being is declared to be

beyond the reach of thought, as not possessing any of the qualities by which the human mind is able to comprehend intellectual or material entity. See **VEDĀNTA**.

The sects which arose during the third period of Hinduism suppose that their worship is countenanced by the Vedas; but its real origin is derived from the *Purānas* and *Tantras*. There are three chief divisions of these sects—the adorers of Vishnu (Vaishnavas), of Siva (Saivas), and of the wives or female energies of these gods (Śāktas). For the philosophy, literature, &c., see **SĀNSKRIT**.

The Popular Faith.—This must be noted as it is seen among the Hindus to-day. The triad of Brahma the creator, Vishnu the preserver, and Siva the destroyer is still remembered. One of them (Brahma) has lapsed into an abstraction, and practical adoration is divided between the other two. The Sivaites are chiefly, but not entirely, in the north; the Vishnuites in the south. The Sivaite worship is chiefly attracted by the wife of Siva, under various names—Kālī, Dūrga, Parbatī, and so forth. Vishnu, again, is almost lost in the worship paid to his two incarnations (avatars), Rama and Krishna. Lesser divinities, such as Hanuman, the 'monkey-god,' and Gaṇeś, the 'elephant-god,' are also honoured. The sanctity of the Ganges (Ganga) remains, and when the river is lost in the delta that sanctity is to some extent continued to the Hooghly, flowing past Calcutta. The Nerubudda also is sacred. The ling or phallus is still an emblem, and gives its name to the Lingayet sect in the Deccan. It is hard to gauge the thoughts of Hindus regarding a future state. They think of a heaven (Swarga) and a hell; also of giant demons (Rakshas). From their demeanour in the presence of certain death it may be inferred that they expect absorption into the divine essence or entity, through the intervention of the god or gods they have worshipped. It is hard to measure the extent to which this faith may have been weakened by the western education of to-day in the minds of the rising generation. The undermining is, however, extensive. Still, in the upper class there are many who cling to Brahmanic orthodoxy, and with the mass of the people the adoration at the temples, the floral and votive offerings, the ceremonies, the festivals, the pilgrimages, are all maintained. The rule of life is still comprehended in the term Dharma, which includes religious fidelity and moral virtue.

The Caste System, which is a potent factor in the national life, does not appear to have been a part of the Vedic religion originally. But it arose subsequently with a religious sanction which is still maintained. The Brahman caste, including the priests, is held to have something divine in it. Most of the several millions of Brahmans follow secular employment; but even the humblest of them is hedged round by a certain sort of sacredness. This caste, together with the Kshatri or warrior caste, and the Vaisya or trader caste (including the subdivision of Kayasths or writers), are held to be twice-born (dwija). This character does not attach to the Śūdra caste, which includes the masses. The restrictions in respect of food and drink (water) in the caste system are most severe and narrow. Caste is lost from any of the infringements that are inevitable in foreign intercourse. But restoration to caste, though often expensive, is sufficiently facile. Within each caste as a division of the people there are subdivisions infinitely numerous, which as a whole have been reckoned at several thousands. See **CASTE**.

The Brahmos.—But a new religion is arising among the Hindus educated after the western manner: this may be termed Brahmoism or

theism. Their community is termed the Brahma Samaj (q.v.). These theistic reformers look primarily to the Vedas, but refer also to the Christian Bible, eschewing caste and almost everything Brahmanic. This intellectual, moral, and spiritual movement may have infinite development under the national education now established, and is to be reckoned among the phenomena of the country. Even more important politically and socially has been the Arya-Samaj (q.v.), a reformed and theistic Hinduism, professedly based on the Vedas, and not on any Christian or alien doctrine or authority.

The Sikhs.—Their faith, though not quite what it was in the preceding generation, is still a living power. In the Punjab and the protected Sikh states it really was a sort of reformation, and a moral system engrafted on Brahmanism. Otherwise it recognises all, or nearly all, the Brahmanic tenets, caste included. Its sacred book, the Granth, is well known. Its spiritual teachers (Gurus) have a status irrespective of the Brahman priesthood, and it has religious orders endowed with fighting qualities. A man is not born into its system, but is initiated. Practically the initiated ones are all Hindus, who thus become Sikhs or disciples. There are two modes of initiation, something like baptism: the first, that of the foot, practised by the founder, Baba Nānak; the second, that of the sword, as practised by Govind Sing, the warlike propagator. The former has more of a religious character, the second is more militant. The popularity of the latter culminated in the palmy days of the Sikh kingdom, when the temple of initiation at Amritsar, near Lahore, was daily crowded.

Buddhism is now for the people only a *nomini umbra*; probably the words 'buddh,' as abstract wisdom, and 'nirvāna,' as a haven of celestial quiescence, are remembered. In the Eastern Himalayas, Sikkim, and Bhutan it is really Lamaism (q.v.), or the medieval corruption of Buddhism, of which the headquarters are at Lhasa, in Tibet, with the Dalai Lama and the incarnations. The representations of Buddha or Gaṇtama have the aspect of ineffable repose which Buddhism has everywhere exhibited. The caste system does not exist, but the monastic order is all-powerful. In Burma the faith is still mainly that which was settled at the last great council of Asoka, in northern India, before the Christian era. Here also caste is not acknowledged; but the priestly and monastic orders, though they cannot arrogate a status like Brahmans, are very influential.

Jainism is believed to have originally sprung from the same school of speculative thought as Buddhism. It has sacred books and saints of its own, in a long line or series, and it promises a future quiescence hardly distinguishable from annihilation. It has an excessive tenderness for animal life. It recognises caste. Its adherents are largely found in the banking and mercantile classes.

Mohammedanism.—This is, in many parts of the country, strict and exactly preserved, and 'din,' or orthodoxy, is still a word to conjure with. The two sects, Sunnis and Shīahs, exist in this as in other countries; the dynasties have been mostly Sunni, and the people chiefly belong to that sect, but the Shīahs have always been numerous at Lucknow. In eastern Bengal, however, the faith is much modified and debased, and this remark applies to nearly half of the Moslem population. The ramifications of the fanatical Wahabī sect in Arabia have spread to the Indian empire, thereby causing occasionally political trouble.

The Parsees preserve the Zoroastrian faith and practice—the fire-worship, and so forth. Their

'towers of silence,' inside of which the dead are deposited, are conspicuous objects. There are traces still in India of the old worship of trees—the Bo, the tulsi, and others, and of the serpent (Naga). The aboriginal cult consists of veneration for the great spirit and for malignant powers, including smallpox, and even the tiger, with worship of stocks and stones.

Religious Endowments.—The several religions have from time immemorial received endowments from the native dynasties, which endowments are in part maintained under British rule. The value of these endowments consisted in the alienation of the land revenue in favour of religious institutions as grantees. The government has severed itself from any share in the management of these institutions, but it regards the landed endowments as property, and has maintained them after due investigation of tenure, title, and the like.

Christianity.—The traditions of St Thomas (q.v.) the Apostle survive in the south, where also a Syrian Church was planted in the early centuries after Christ. In the 5th century Nestorianism came from Babylon, and still survives. In the 16th century Roman Catholic missions arrived from Portugal, and soon afterwards came the famous St Francis Xavier (q.v.) with the Jesuits. The Jesuit missions had great success on both sides of the Peninsula in a certain way, but their ministers were somewhat orientalised. Just two centuries later—i.e. at the middle of the 18th century—the Society of Jesus was broken up in Europe, and the south-Indian missions languished in consequence. Early in the 19th century the society was re-established, and ere long its missions were resuscitated.

The Danish settlement on the south-east coast at Tranquebar saw the first Protestant mission, which was Lutheran, under Ziegenbalg, in 1705. He was followed by Schwartz (1750) in the Peninsula. Towards the end of the century the Baptist mission was set up at the then Danish settlement at Serampore. In the early years of the 19th century Henry Martyn, the Church of England chaplain, began to work as a missionary. The bishopric of Calcutta was established in 1814, and then followed the operations of the two great associations of the Church of England—the Church Missionary Society and the Society for the Propagation of the Gospel. The Church of Scotland began its missions in 1830, the Free Church after 1843. Next came the Wesleyan and Baptist missions (British and American), the Basel, the London Missionary Society, the United Presbyterian. In 1835–37 the bishoprics of Madras and Bombay were established, the Bishop of Calcutta becoming Metropolitan; and now there are bishops for the Punjab and Sind, for the United Provinces of Agra and Oudh, for the Central Provinces, and for Burma, besides five missionary bishops for the Peninsula. There is no state church established by law in India, though in a sense the Church of England is the church of the government. Presbyterian chaplains are also provided at certain centres, and in many places are ministers of other denominations. Roman Catholic priests are ministering everywhere, and many of them are salaried by the government as ministers to the European soldiers of their faith. Besides these there are the European ordained missionaries—many hundreds of all denominations—and under these a fast-growing native ministry.

The following was the distribution of the Christian population, by race, in India in 1921: European, 175,737; Anglo-Indian, 113,041; Indian, 4,464,396—total, 4,753,174. More than one-third of the total are in the Indian states. The following

is according to denomination at the census of 1921: Church of England, 533,180; Presbyterians, 254,838; other Protestants, 1,180,313; Roman Catholics, 1,823,079; Syrians, 791,556; all others, 170,208—total, 4,753,174.

The missionaries have now, for more than a century, worked with pastoral devotion, literary labour, and educational efficiency, in Western as well as Eastern knowledge. They have studied religions, translated the Scriptures into the principal languages, issued numerous works on Christian teaching, supervised schools, founded colleges, managed the cure of congregations. They have long constituted a moral force in the country, with beneficial effect, socially and politically. The increase in the number of native Christians has been proportionally great.

Social Customs.—Four-fifths of the population are affected largely by the caste system already described as being partly at least connected with the popular religion. A religious sanction in some degree attaches to infant marriage, or child marriage, with all classes; also to the seclusion of women, and to the prohibition against re-marriage of widows, with the upper and middle classes. In practice the women of the masses are not secluded, but, on the contrary, appear everywhere, and work out of doors; they re-marry, too, if in widowhood. The burning of widows (suttee or sati) on the funeral pyres of their husbands has long been suppressed by the criminal law under British rule. Polyandry is found only among a few of the aboriginal tribes. Polygamy is sanctioned, but not enjoined; it is, of course, confined to those who can afford to maintain more than one wife. Here, again, in practice the masses of the people are monogamist. In all classes the marriage expenses, arising chiefly from the offerings made to the priesthood, are so excessive as frequently to cause embarrassment to families. Many of the social customs above indicated are regretted and deprecated by native reformers as being injurious to the national progress, and benevolent efforts for reformation are made. The laws of inheritance, dower and divorce, women's property, adoption, partition, and other social matters are held to have a quasi-religious sanction. They are generally observed in the courts of justice under British rule, both for Hindus and Mohammedans. Three criminal practices have been severely dealt with by the British government: female infanticide, arising from the presumed exigencies of caste; the murderous and treacherous Thuggee connected with the goddess of destruction; and the Meriah or human sacrifices by some of the hill-tribes.

The Village System.—This is a factor in the rural life of the Hindus, and from them has been adopted by the Mohammedans. A village does not merely mean a collection of houses, but corresponds to a township or a parish. It is an area of some hundreds or thousands of acres of land, according to circumstances, and is under the administration of hereditary functionaries, the principal of whom is the *potail* (head-inhabitant), a small local magistrate, who superintends the affairs of the community, settles disputes, attends to the rural police and the collection of taxes. Among the other functionaries may be mentioned the accountant and notary (*kurnum* or *patwari*), who keeps a register of the produce and the names of the proprietors, and draws up all deeds of sale, transfer, &c.; the Brahman, or village priest; the schoolmaster; and the watchman. Besides these almost every village has its astrologer, smith, carpenter, potter, barber, and bard, all of whom are rewarded out of the produce of the village-lands. 'Under this simple form of municipal government the inhabitants of the country have lived from time immemorial.'

The boundaries of the village have been but seldom altered; and though the villages themselves have been sometimes altered, and even desolated by war, famine, and disease, the same name, the same limits, and even the same families, have continued for ages. The inhabitants give themselves no trouble about the breaking up and division of kingdoms; while the village remains entire they care not to what power it is transferred, or to what sovereign it devolves; its internal economy remains unchanged; the potail is still the head-inhabitant, and still acts as the petty magistrate.

Costume.—This is in these numerous nationalities characterised universally by the ease, lightness, and looseness common in the East and suitable to the hot climate. But it varies in the many provinces, and, indeed, with every nationality. The turban (*pagri*) has every sort of dimension, from minute neatness to turgid massiveness. The waistband (*dhoti*) extends often below the knee, in which case there is no trouser. Jackets in many styles are common. The women's dress in many respects resembles that of the men. The petticoat is not universal. The head-dress is often extended, so as to hang gracefully down the back. The shoe is not always worn; indeed, the humbler classes are generally barefooted. With them the blanket is often a plaid. The black colours of Europe are seldom seen, but indigo blue is common. Otherwise white, set off by gay margins, and rich scarfs and shawls, is the prevailing colour. As a whole the national dress is picturesque, and a holiday crowd has the appearance of a flower-garden.

Architecture.—This is not generally remarkable in the humbler dwellings. In the Gangetic delta the materials are bamboo and thatch, and the cottages, being covered with creepers, are picturesque. In the north both walls and roofs are of indurated earth, the effect being utterly plain. In the south wood and brick are used. The street architecture in the cities and towns is diversified in a manner conducing to pictorial effect. The Europeans have not invented any style for their buildings, except at Calcutta, where the private houses have a stately architecture suited to the climate. Otherwise for their churches they have adopted the Gothic style, and for their civil structures the leading styles of Europe, with certainly a noble, even magnificent effect at Calcutta and Bombay. At Madras, in Rajputana, and elsewhere, they have used adaptations of the old oriental styles.

The indigenous styles of architecture for many centuries have been the chief ornaments of the land. Their study has been greatly elucidated by the Archaeological Survey. They begin with the Buddhist era; for the preceding or Vedic era there are no remains. The best authority regarding them is Fergusson, from whose works the following classification is taken. It must suffice to note the salient points only.

The Hindu Styles.—In the Buddhist architecture the characteristic features are, first, the *Tope* (a corruption of *Stupa*, or 'monumental mound'), encased with masonry, having a superstructure at the top, and corridors round the base, with four entrances marked by gateways, often of great beauty; secondly, the *Lati* or pillar, generally monumental; the *Chaitya* or hall of worship; the *Vihara*, or monastery, with cells for the monks. The two last named are often rock-cut, and thus have an extraordinary interest. One tower only, that of *Buddh Gya* in Behar, has been found, and it is one of the noblest dimensions. Almost all parts of the architecture are adorned with bold yet graceful carvings of men and women, and of animals. In some of the rock-cut chambers or cave-temples are remains of frescoes immensely valuable to the student.

The only living architecture of Buddhism is in the Eastern Himalayas, in Sikkim. There the figures of Buddha are beautifully executed in terracotta; and the monasteries are protected from the snow by umbrella-shaped roofs. In Nepal there is one tapering pagoda in the Burmese style. In Burma the circular dagobas have been developed into the exquisitely-tapering pagodas, with gilded surface, and the masonry is set off by wood-carving of the most elaborate description.

In the Jaina architecture the original characteristics were somewhat similar—Jainism and Buddhism being cognate faiths. But simplicity begins to be lost in ornament. Extensive remains are discovered on hill-tops far removed from one another—Parasnath in Bengal, Abu in Rajputana, Satranj in Kathiawar. There is a disposition to congregate small temples in great number on hill-tops, so as to form, as it were, cities of the gods. The general effect of these, however, is not picturesque. The large towers become rounded and ribbed, with a circular addition something like a rose on the apex, surmounted by a finial, so that the general effect is not unlike a spire. Arches and domes become prominent features. Elaborate ornamentation is introduced into the stone masonry. Pillars and lesser towers of great beauty are erected.

The styles which follow are historically Brahmanic. In the Himalayas there are two styles: one in Kashmir, with Hindu affinities, but with greater simplicity of outline and of detail in gray limestone; the other in Nepal, with Chinese and Burmese affinities, the most striking examples being those of temples built in stories, with sloping roofs, copper-gilt, and projecting eaves; the walls being often of enamelled brickwork, and the wood-carving very rich.

The Dravidian style prevails in the southern peninsula, where the Tamil language is spoken. It is called after the old Dravidian race, which has still a distinctive existence in this region. The towers of the temples lose the rounded and spiral forms, and become nearly pyramidal. The temple enclosures have vast gateways (*gopuras*) of comparatively square shape, though narrowed towards the top. The surface ornamentation, though very fine in some respects, is on the whole grotesquely profuse. At some points, however, the redstone sculptured figures are superb. Granite is largely employed in this style, also the exquisite stucco obtained from shell-lime. The styles heretofore mentioned were devoted almost entirely to religious purposes. But this Dravidian style is adapted to civil uses, and appears in stately palaces, public offices, pavilions, elephant-stables, and so forth. This has been ascribed to the influence of Mohammedan example. The arch becomes prominent; and at Madras especially there is an arched hall of real magnificence.

The Chalukyan style is named after a Hindu dynasty that reigned in the central Deccan. It is found originally in that region, but extended to Mysore, where its noblest works were arrested in their construction by the Mohammedan invasion. Its materials are often of volcanic and granitic stone. The pyramidal shape prevails, and the patient elaboration of surface-ornament excites wonder; but in the general outline stiffness and solidity prevail over gracefulness.

The Indo-Aryan or Brahmanic style is more widely spread than any of the others, extending as it does throughout the northern and central regions. Its examples are varied; many are too small to be effective or significant, but some, such as the group near Jaganath, in Orissa, and that at Brindaban, on the Jumna, are of the grandest type. Artistically the Orissa examples are perhaps the

best in the whole country. The forms are influenced by Mohammedan example. The rounded and coroneted tower already mentioned in the Jaina style is found to perfection here. In northern India it is called the *Shiwāla*. This style is adapted not merely to temples, but to cenotaphs for the repose of ashes after cremation, to palaces and summer-houses, to fortresses, to the dams of artificial lakes, to travellers' rest-houses, to wells, and to the spacious reservoirs that are famous under the name of *Baoli*. The domes and lesser cupolas become frequent. The balconies and windows are much to be admired. One palatial summer-house at Deeg, in Rajputana, is one of the most beautiful buildings of its kind in the world. The modern Hindu work chiefly belongs to this style, and is still going on. In general terms, observation of nature, aspiration for beauty, and artistic feeling have characterised the Hindus—whether Buddhist or Jain or Brahmanic—and imparted to their architectural achievements an art-culture rarely surpassed by any nationality.

The Indo-Saracenic Style.—This may be divided into two parts, the Pathan and the Mogul. It begins with the 11th century, and ends with the 15th. The early Pathan style, whether in stone, as at Ahmedabad, near the west coast, or in brick, as at Gaur, in Bengal, far eastwards, consists, with one notable exception, of the Hindu architecture already described, but adapted for a simple worship, and modified with a certain breadth of conception to which the Hindus never attained. The exception is this, that sculpture of the human form is excluded, as being idolatrous. The later Pathan style was based on northern models. Plainness and grandeur are its characteristics, both in the northern and the central regions. The dome, the arch, the minaret are nobly developed; indeed, the dome at Bijapur, in the Deccan, is the grandest object of its kind in the world, and is equally remarkable for structural skill.

The Mogul style began with Akbar the Great in the 14th century. At first it appeared in a somewhat Hinduised form, because the Moslem princes married Hindu princesses. But it soon became purified from a Moslem point of view, and resumed the severe simplicity and grandeur of the later Pathan style, superadding thereto a grace and dignity never surpassed in human art. At first the materials were red sandstone and marble intermixed. But by degrees marble was used more and more, till the culminating example of this style, the Taj Mahal at Agra, was encased entirely with this material, inlaid with precious and parti-coloured stones (see illustration at AGRA). After this the Pearl mosque (marble) at Agra and the palace fortresses at Agra and Delhi, and the Jama mosques at Delhi and Lahore (Punjab) are the most renowned examples.

The Indo-Saracenic style is applied largely to tombs, it being the practice of the sovereign to erect his tomb in his own lifetime. Besides this class and the other classes of structure, it was largely applied to caravanserais and to educational institutions (*Madrasas*). In all its later stage, it was marked by surface decoration in coloured enamel on earthen material, with hues of which the brilliancy and quality cannot be imitated in modern times. After the break-up of the Mogul empire, a debased modification of the style was introduced at Lucknow. High as was the art culture in the architecture of the Hindu predecessors, it was even surpassed by the Moslem successors.

III. GOVERNMENT AND MILITARY DEFENCE.

The Empire.—Since Queen Victoria was proclaimed Empress in 1877, India is an empire, includ-

ing the British territories and the Indian states, or, in other words, the Indian allies, feudatories, and vassals of the said empire from the Tibetan and Tatar watershed of the Himalayas to Cape Comorin. It includes, too, every acre within their geographical limits, without any exception, save the comparatively small settlements belonging to France and Portugal. The empire is under one supreme authority in India—viz. the Governor-general (popularly 'Viceroy') in Council. It may be divided into two categories—the British territories, comprising about three-fifths of the total area, and nearly four-fifths of the total population; and the native states. It will be convenient to dispose of the latter first.

The Indian States.—The relations between these and the British government are regulated by treaties in full detail. These treaties have been published in many volumes, and form a record of the utmost value to the student of modern India. Some states do not ordinarily appear in the official tables, though they form an integral part of the empire and are in communication with British political agents. In their internal affairs they are uncontrolled. These are the important Himalayan state of Nepal, and the lesser states of Sikkim and Bhutan. The native states which appear in the official tables occupy more than a third of the area of the Indian empire, and contain more than one-fifth of its entire population. They are, thus grouped in the census table of 1921:

Native States	Area in sq. miles.	Population, 1921.
Assam State (Manipur).....	8,456	384,016
Baluchistan States.....	80,410	878,977
Baroda State.....	8,127	2,126,522
Bengal States.....	5,434	896,926
Bihar and Orissa States.....	28,648	3,959,669
Bombay States.....	68,458	7,409,429
Central India States.....	51,581	5,997,023
Central Provinces States.....	31,176	2,066,900
Gwalior State.....	26,857	3,186,075
Hyderabad State.....	82,698	12,471,770
Kashmir State.....	84,258	3,320,518
Madras States.....	10,696	5,460,312
Mysore State.....	29,475	5,978,892
North-west Frontier Province (Agencies and Tribal Areas).....	25,500	2,825,186
Punjab States.....	37,059	4,416,086
Rajputana States.....	128,987	9,844,884
Sikkim State.....	2,818	81,721
United Provinces States.....	5,949	1,124,851
Total.....	711,082	71,939,187

The corresponding total population in 1911 was 70,888,854. Hyderabad as given above is exclusive of Berar, which, though part of the Nizam's Dominions, is administered as part of British India.

The relations of the Indian princes to British authority differ very widely. Some are practically independent sovereigns, except that the suzerain power does not permit any of them to make war on one another, or to form alliances with foreign states; while some are under tolerably strict control. As a rule they govern their states under the advice of an English resident appointed by the Governor-general. Thus at every considerable Indian court there is stationed a British agent, political or diplomatic. There are in all about 693 states, allied or feudatory, great and small, of which 175 are in political relations with the government of India.

Another classification is mainly according to the religion and race of the reigning dynasty:

I. *Mahratta*. The chief states are: (1) Gwalior or Sindhia (pop. 3,186,075); (2) Indore or Holkar (pop. 1,133,277); and (3) Baroda (pop. 2,126,522). These are Hindu in faith, but may conveniently be distinguished from the other Hindu states. See MAHRATTAS.

II. *Hindu*. Of these the chief are: (1) Mysore (q.v.; pop. 5,978,892); (2) the Rajputana states, such as Udaipur or Mewar (pop. 1,380,063), Jeypore (pop. 2,338,802), Jodhpur (pop. 1,841,622), and some

18 smaller states; (3) the Madras states, such as Travancore, Cochin, Pudukota; (4) the Bombay feudatories, over 360 in number; (5) the lesser states of Central India, including Rewa and Bundelkhand; (6) Punjab states, including the protected Sikh states, 10 larger and 24 smaller, Patiala being the largest.

III. Mohammedan. The greatest are: (1) Hyderabad of the Deccan, or the Nizam's Dominions (pop. 12,471,770, of whom three-fourths are Hindus, though the dynasty and military power are Moslem); (2) Bhopal (pop. 971,387, nine-tenths Hindus by faith); (3) Bahawalpur (pop. 781,191).

IV. Frontier, mainly Himalayan and north of Bengal and Assam. (1) Kashmir with Jamu (pop. 3,320,518); (2) the Pathan (Afghan) tribes; (3) Manipur (pop. 384,016); (4) Bhutan (pop. 250,000); (5) Nepal (pop. 5,600,000).

The feudatory states (excluding Nepal and without counting small states which have no armies) have together armed forces amounting to 93,000 men. In addition, 29 states contribute contingents of imperial service troops aggregating about 22,000 men, comprising 10,000 infantry, 7500 cavalry, 700 sappers, transport and camel corps of 2700 and 700 respectively. Gwalior contributes nearly 4000 men, and Kashmir over 3500; Patiala, Hyderabad, and Alwar over 1000 each. These troops are available for imperial service when placed at the disposal of the British government by the rulers of the states to which they belong. They are under regular inspection by British officers. They rendered valuable services during the Great War.

These states are loyal to the British crown as paramount and suzerain. Their loyalty was proved during the imperial crisis of 1857-58, and in the war of 1914-18. In the aggregate they form a preservative and constitutional force in the country. The British government takes a paternal interest in the welfare and good government of these states. Misgovernment is effectually prevented. Colleges and schools under British auspices are established for the education of young native princes.

As descendants are frequently wanting in these old families, it was important that the principle of adoption should be recognised, otherwise the state might on the death of the native prince without issue lapse to the British government as paramount. All fears on this account were set at rest by a decree in 1858 sanctioning the right of adoption according to Hindu or Mohammedan law.

The British Territories.—These, containing 1,094,300 sq. m. and 247,003,293 (1921) souls, are broken up into nine major provinces and six minor. There were originally but three divisions, the 'Presidencies' of Bengal, Madras, and Bombay.

Provinces.	Area in sq. miles.	Population, 1921.
Ajmer-Merwara	2,711	495,271
Andamans and Nicobars	8,143	27,086
Assam	53,015	7,606,220
Baluchistan	54,228	420,648
Bengal	76,843	46,695,586
Bihar and Orissa	83,161	54,002,159
Bombay	133,621	18,943,219
Burma	233,707	13,212,192
Central Provinces and Berar	99,876	13,912,760
Coorg	1,582	163,338
Delhi	593	483,138
Madras	142,260	42,318,935
North-west Frontier Province	13,419	2,251,340
Punjab	99,846	20,635,024
United Provinces of Agra and Oudh	106,295	45,375,787
Total	1,094,300	247,003,293

Burma in the foregoing table includes the Shan States, the Chin Hills, and the Karen country. The North-west Frontier Province was formed in 1901 out of Peshawar, Kohat, and parts of three other Punjab districts, and areas occupied by frontier tribes from Baluchistan to Chitral, not previously included in India. The United Provinces were

till 1901 the North-west Provinces and Oudh. Bombay Presidency includes Sind and Aden. Berar was in 1905 joined to the Central Provinces. Bengal, divided in 1905 into Bengal and Eastern Bengal and Assam, was repartitioned in 1912 into Bengal, Bihar and Orissa, and Assam, when Delhi was detached from the Punjab.

These figures, large as they are, fail to give a definite impression of the enormous area and population under British authority in this part of the globe. The districts under direct British administration have an area more than seven times that of the United Kingdom. The area of the native states is as large as Norway, Sweden, Spain, Holland, and Belgium put together. The British territories (without the native states) contain more than one-seventh of the inhabitants of the entire globe.

Machinery for Governing.—In 1858 the government was transferred from the East India Company (q.v.) to the crown. In 1877 Queen Victoria assumed the title of Empress of India (Kaisar-i-Hind). The government of India is in the highest resort vested in a Secretary of State in London, who is a member of the cabinet, and has a parliamentary under-secretary and a council of eight to twelve members. The executive government in India is administered by the Governor-general in Council, acting under the control of the Secretary of State. The Governor-general, appointed by the crown, has an executive council, which consists of as many members as the king may think fit to appoint. The Indian legislature consists of the Governor-general and two chambers, viz. the council of state and the legislative assembly. The council of state consists of not more than sixty members, nominated or elected in accordance with rules made under the Government of India Act. The legislative assembly consists of 140 members, of whom 100 are elected and 40 nominated. Among the nominated members are 26 officials. The proceedings in both chambers are public.

As the result of changes due to the Government of India Act, 1919, in nine major provinces—Bengal, Madras, Bombay, the United Provinces of Agra and Oudh, the Punjab, Bihar and Orissa, the Central Provinces, Assam, and (later) Burma—the government consists of a governor, an executive council of not more than four members, and two or more ministers. The six minor provinces are administered by the central government of India through chief commissioners. Coorg is under a commissioner.

The provincial governors have each a legislative council for provincial legislation. The governors are appointed by the crown. The executive government in governors' provinces is a dual organisation. Reserved subjects are administered by the governor and his executive council appointed by the king, transferred subjects by the governor acting with the advice of ministers, who hold office during his pleasure, and must be members of the provincial legislative council. The more important transferred subjects are local self-government, medical administration, public health, education, public works, agriculture, excise, and development of industries. The members of the legislative councils are now appointed some by nomination and, since 1910, some by election.

The Units of Administration.—The larger units are the districts (generally called collectorships in English and *zillahs* in the vernacular), of which there are in all the provinces above mentioned about 270. Each district, if in regulation territory, is under a collector-magistrate; if in non-regulation territory, a deputy-commissioner. The head of the district has most multifarious and responsible duties; he is fiscal-officer, charged with collecting the revenue, as well as magistrate, and besides

superintends police, jails, education, sanitation, and roads. In parts of the non-regulation territory he is also the civil judge, but not in regulation territory. The subordinate officers are deputy-collectors and assistant-magistrates. The district may be compared to an English county or a French department, and varies in size from an area containing 3,000,000 inhabitants to one with only 50,000. Within the district the lowest unit is the village or parish (*mouzah*), according to the village system already described. There are about 550,000 such villages or parishes in the British territories. In all the divisions of the empire, except Madras, the districts are formed into groups, several to each group, under a commissioner. Of these there are more than fifty.

The State Services.—The administration is conducted by members of the Indian civil service (formerly called the covenanted) and the provincial civil services. The Indian civil service is recruited from the successful candidates at competitive examinations held in London, and (since 1922) in India, but a few vacancies are filled by nomination of natives of India and Burma by the government of India. The Indian civil service is at present predominantly European, but in accordance with the present policy of government the proportion of Indians is to be increased until the service consists of almost equal numbers of Europeans and Indians. Special provisions were made under act of parliament for nominating to the Indian civil service in 1919 and 1920, without competitive examination, persons who served in the war and more than thirty natives of India. To this service most of the higher administrative appointments are secured by act of parliament; but governments in India may, subject to rules approved by the Secretary of State for India, appoint *natives of India* to offices reserved for the Indian civil service. Members of the provincial civil services may be promoted to offices reserved for the Indian civil service. These provincial services, appointments to which are made by the authorities in India, are composed of natives of India including domiciled Europeans. Some other Europeans are appointed in England, especially those who belong to scientific departments and the Indian educational service.

The European community—merchants, manufacturers, barristers, lawyers, and other professional men—constitutes a force of independent opinion, mainly in Calcutta, Madras, Bombay, and some of the other larger cities. It is supported by an English press, published not in the 'presidency cities' merely, but in the provincial capitals and elsewhere.

The Army.—In 1859 the troops of the East India Company became the Indian military forces of the British crown. The forces were divided into three armies, named after the 'presidencies' of Bombay, Madras, and Bengal. But this arrangement was found to be inconvenient and faulty, as only the Bengal army was under the direct control of the commander-in-chief, and in 1895 it was abolished and the army divided into four 'commands'—Punjab, Bengal, Bombay, and Madras—each under a lieutenant-general, under the direct control of the commander-in-chief. Lord Kitchener (commander-in-chief) in 1904 made considerable changes in the organisation of the army towards greater efficiency and preparedness for war in the distribution of the troops. The regiments of the native army were renumbered, and the distinguishing names of Madras, Bengal, and Bombay as parts of the army abolished, and the special corps, the Hyderabad contingent, the Punjab Frontier Force, &c., were all absorbed into the line. There are now four commands divided into fourteen districts, comprising 37 brigades and brigade areas. An Indian

Staff College was established in 1905 at Quetta and a Military College at Delhra Dun in 1923. In 1924 the total strength of the army in India was about 280,500, and consisted of: British Army, 60,500; Indian Army, 137,000; Auxiliary Force, 35,000; Indian Army Reserve, 32,000; Indian Territorial Force, 16,000. In addition there are the Indian State Troops, formerly called the Imperial Service Troops, maintained by certain of the feudatory states. These number about 37,000. The Indian troops are recruited by voluntary enlistment, with good prospects of pay and pension, from all nationalities and from all castes, Brahmans or others. Though the regiments are commanded by European officers, there are Indian commissioned as well as non-commissioned officers, and in 1923 eight units were selected for complete Indianisation as soon as possible.

The Maritime Force.—The special force of ships and men furnished by the East India Company's navy was abolished after a long and honourable career in 1863, and the command of Indian waters was undertaken by the royal navy. Six or seven vessels are stationed in these waters, with headquarters at Bombay, under an admiral commander-in-chief. Bombay harbour for spaciousness and defensibility ranks in the first class of harbours in the world. Madras has merely an open roadstead. But Calcutta has to be approached by eighty miles of river-navigation, which can be conducted only by pilots of life-long training; and it is therefore absolutely defended by nature. Rangoon, near the mouth of the Irawadi, has a similar advantage, but in a lesser degree. Kurrachee, near the mouth of the Indus, though good, is not large enough for the importance of its situation.

Two great steam-navigation companies, with headquarters in London, but plying in eastern waters, form an addition to the maritime resources of the country for war or other emergency. Their ships, though officered of course by Europeans, are manned chiefly by Mohammedans from the coast districts (Lascars), who are excellent sailors.

IV. CIVIL ADMINISTRATION.

Law and Justice.—The fundamental institutions of the Indian empire have been established by parliament in a series of statutes, consolidated in 1915 into one act entitled the Government of India Act. The regulations of the East India Company provided for civil procedure, leaving the native laws to be observed in social affairs, and British justice to be followed in other affairs. The supreme courts established by the crown in the presidency towns of Calcutta, Madras, and Bombay, towards the end of the 18th century, administered the English law. In 1833 the English government set up a commission to frame a body of substantive law, civil and criminal, for the British-Indian territories. This commission and its successors laboured up to about 1850; and with their help a penal code, a civil procedure code, and several other fundamental laws have been passed. The legislative work, both civil and criminal, is highly scientific as well as practical, and is framed after the best models to be found anywhere. In 1853 a legislative council in India was set up. In addition to this several local legislatures were established in 1861, and these have since been enlarged. About the same time the supreme courts were abolished, and in their stead High Courts were established to control the whole administration of justice inside and outside the presidency towns. Courts of various grades exist in all parts of the districts already described, so as to be accessible to the people. In such a society as that of India there must needs be defects and shortcomings in the judicial system, but on the whole it commands

popular confidence, as is proved by the extent to which it is brought into use. In the criminal department about 1,600,000 crimes and offences are reported annually; for these cases about two million persons are brought to trial, of whom about half are convicted. The suppression of gang-robbery and other crimes of overt violence forms a marked feature of British administration—besides the extinction of the criminal practices mentioned under the head of *Social Customs*. See *Anglo-Indian Codes*, ed. Whitley Stokes (1887-91).

Police and Prisons.—The regular police comprises a force of 206,000. The constabulary is a native force, the principal officers only being for the most part Europeans. It is subject in all respects, except internal discipline, to the magistracy, and in each province is under an inspector-general. There is one regular constable to 6 sq. m. and 1500 inhabitants—which indicates the peaceful habits of the people. Besides the regular police there are village watchmen. Great care has been taken in the scientific construction and supervision of a prison in almost every district. There are upwards of 750 jails, with about 115,000 prisoners, exclusive of 11,000 transported to the convict settlement at the Andaman Islands.

Education.—The existing system may be dated from 1854, though various efforts had been made long before that date. Measures have been passed allowing municipalities or other local bodies in Bombay, Bengal, the Punjab, the United Provinces, and Bihar and Orissa to enforce primary education within their jurisdiction. There are universities at Calcutta, Madras, Bombay, Allahabad, Lahore, Patna, Benares, Dacca, Aligarh, Lucknow, Rangoon, and Delhi. These, while only examining bodies, have affiliated colleges, in which a prescribed education in arts, law, medicine, engineering, teaching, veterinary science, commerce, forestry, and agriculture is given. The pupils attending these colleges in 1920-21 numbered 61,324, of whom 1388 were females. Of the total number 9814 graduated—in arts, 6699; medicine, 425; engineering, 117; other faculties, 2573. A proposal for a university at Nagpur is under consideration. Mysore state has a university. The educational institutions are of several kinds, public, aided, private, and unaided; all together they amounted in 1920-21 to 206,158 in number, with 8,377,027 scholars. These numbers, though actually large, are not so relatively to the population. Of the total students 1,412,979 were girls. The income comes from various sources, including provincial revenues, local rates and cesses, municipal funds, endowments, and fees paid by the parents. The English language, with Western literature, arts, and sciences, is taught to the upper students everywhere. Much remains to be desired in physical science, and technical instruction is in its infancy; the native mind has until quite recently shown a tendency towards literature rather than exact science, towards the cultivation of the memory and the imagination rather than of the reasoning faculties. But intellectual assiduity is evinced in a commendable degree. There are numerous missionary colleges. Schools of art have been organised in the capital cities; there is an imperial museum at Calcutta, and museums in all the chief cities and towns. The native languages, classical and vernacular, are now cultivated more sedulously. A vernacular literature of primers and elementary works, also of more advanced works, chiefly translations, is springing up under the auspices of the British authorities, vast numbers of such works appearing annually.

Trade.—Of the imports the principal item consists of cotton goods; the next most important are sugar, metals, machinery, railway plant and rolling-stock,

hardware, oils, provisions, manufactured silk, and woollen manufactures. Among the exports the principal items are coffee, cotton (raw, twist, and yarn) and cotton manufactures, grain (including rice and wheat), hides and skins, jute (raw and manufactured), seeds (oil chiefly), tea, wool, dyes, and manganese ore. The growing exportation of food-grains in vast quantities has disturbed or dissipated any notion to the effect that the increasing population might be in want of sufficient sustenance.

Communications.—There were in 1921 37,029 miles of railways open for traffic, including over 26,000 miles of state lines, and 4400 miles of Indian state lines.

Road-making was being vigorously prosecuted, but became somewhat superseded by the introduction of railways. Several magnificent trunk-lines have been constructed. Of the total length in the whole country (173,000 miles) about one-fourth has been bridged and macadamised. Similarly the railways compete with the old boat traffic on the great rivers. This traffic, however, still exists to a wonderful extent in eastern Bengal, where the boats of varied size and build form a conspicuous feature in the country.

Manufactures.—These, whether in metals or in fibres, have always been very fine, and are still maintained; local manufactures of cotton goods are very extensive, and most of the beautiful fabrics of all sorts are produced. No doubt foreign trade during the 19th century checked the development of indigenous manufactures. On the other hand, it has stimulated new manufactures, especially in jute and cotton. The cotton-mills at Bombay, organised on the British model, with British capital and direction, but with native labour, have been considerably developed, and have entered into competition for the Indian market. Factory laws on somewhat like English principles, though not with English provisions, have been introduced since 1881.

Irrigation and Canals.—Native dynasties all distinguished themselves in this department; drought and famine have always urged every government to action, and the work was taken up by the British government with its Western skill and capital. The Ganges canal with its branches, the canal systems of the deltas of the Mahanadi, the Godavari, the Kistna, and the Kaveri, are among the greatest works of their kind in the world. Great canals are drawn from the five rivers of the Punjab, and the Indus is to Sind what the Nile is to Egypt. These irrigation canals are but little used for navigation. The total length of these, their branches and distributaries, is calculated at 67,000 miles. Besides the canals there are in many districts artificial lakes; wells also for irrigation are found in most of the valleys everywhere. The value to India of these works it is impossible to estimate. The total area irrigated by all classes of works in India in the year 1921-22 amounted to about 27,750,000 acres, of which 21,000,000 acres were watered by canals.

Famine Relief.—Owing to extensive failures of the monsoon rains at periodically recurring intervals, droughts and famines have occurred. Though the people bore up against their misfortune with admirable fortitude, and brought out reserves of food such as few nationalities could produce, and though the authorities put forth strenuous efforts, yet the loss of life has been sometimes tremendous. Of late the principle has been followed of devoting the entire resources and power of the government to the mitigation of distress or the saving of life. An annual sum is set aside out of current income to meet the cost of relieving distress in time of famine. During the period 1911-21

about £1,000,000 annually has been charged against Indian revenues for famine relief and insurance, including the construction of protective railways and irrigation works.

Municipalities.—Municipal corporations (at Calcutta and Bombay elected by the ratepayers) have been established in all the cities and large towns of the empire, their total number being about 750. In many districts the establishment of district boards, by popular election, for purposes resembling those of county government in England, has been undertaken since 1880.

Vital Statistics and Sanitation.—This subject has for many years past received systematic attention. The water-works at Calcutta, Bombay, and other places rank high among works of this character in any country of the world; and the purification of the drinking-water in many centres of population has beneficially affected the public health. The instruction of the natives as qualified medical men and as medical assistants has for many years been supported by the government. Medical colleges at the capital cities, and medical schools at other places, have been established successfully. There are dispensaries for gratuitous medical relief. Sanitation is everywhere a department of state administration; and every province has a sanitary commissioner. The death-rate for the empire in the ten years from 1911 to 1920 ranged from 28·72 (1913) to 30·84 (1920) per thousand.

Emigration.—Owing to the excessive density of population in several parts of the empire, government for many years encouraged and facilitated emigration to the tropical and subtropical colonies, the annual emigration of coolies in 1892–1902 varying from 13,000 to 26,000. Emigration was, however, suspended in 1917, and has not been resumed. In the ten years to 1916–17 the emigration to Mauritius amounted to 1200 persons; Natal, 21,000; British Guiana, 18,000; British West Indies, 26,000; Fiji, 25,000; Dutch Guiana, 8500; Mombasa, 2200; other places, 5800—total, about 107,000. There is a considerable migration from the plains and low hills of the central regions to the rice-plains of Burma, and also to the tea-plantations in Assam and in the Eastern Himalayas.

Finance.—The currency is in silver rupees, which alone are legal tender—the subordinate parts of the rupee being sixteen annas, and those of the anna being twelve pai (pies) in copper. The monetisation of silver as sole legal tender to an unlimited amount dates from 1835. There is also a government paper currency, legal tender, amounting to about 113 millions sterling in value. The rupee is nominally equal in value to two shillings; and in former days ten rupees were held equal to a pound sterling. While for Indian purposes the finances were generally exhibited in rupees, of which the higher numbers were a lakh or 100,000, and a crore or 100 lakhs, yet for English purposes they were always exhibited in sterling money; thus, a lakh was reckoned as equal to £10,000, and a crore as equal to a million pounds, and for many years the Indian accounts were exhibited in England in sterling by the process of dividing the rupee totals by ten. In the then relative values of gold and silver this plan answered well, for generally ten rupees were really equivalent to one pound or thereabouts. But owing to the depreciation of the rupee, which fell at times below one shilling and a penny in the exchange, this simple plan became no longer possible, though the Indian accounts for England were generally shown in tens of rupees (or ₹x), whereby the comparison between the figures of recent and of former years was maintained. The expenditure has been greatly increased of late years by the depreciation of the rupee. In order to discharge an obligation of 20 millions sterling India had until

recently to remit to Britain 30 millions of tens of rupees; thus it is estimated that, as compared with former years, the depreciation of silver imposed on her a burden of some 10 millions annually (in tens of rupees). In 1902 it was resolved to try to relieve this embarrassment, to some extent at least, by experimental legislation. In 1903 a law closed the Indian mints to the coining of silver; 1s. 4d. was fixed as the gold price of silver; but provision was made that when the value of the rupee rose to this proportion the mints should be again opened. And the value of the rupee did rise considerably. Since 1900 the government returns of Indian finances have been given in pounds sterling, the rupee being valued at 1s. 4d., or ₹15 = £1. The rupee rose considerably above its old value of 2s., but fell again below 1s. 4d.

Banks.—There is a state or presidency bank, with branches, at Calcutta, at Madras, and at Bombay. Besides the three presidency banks, there are twenty-two joint-stock banks having their head offices in India. The savings-banks in India are now only those of the post-office, those connected with the presidency banks having been closed in 1897.

Land-taxation and Land-system.—This claims notice on social and economic grounds as well as fiscal. The tax is collected in money instead of in kind, as was often the case under native rule. It consists of a portion taken by the state from the agricultural rent—and much the smaller portion. Apart from this, the incidence of tax on the value of the gross produce is reckoned to range from 4 to 10 per cent. in the several provinces of the empire. In all these provinces, except Bengal, for the assessment of the tax a survey of every field, besides a general survey of every village, has been made. In every village there is a register showing the ownership, occupancy, rights, and interests in every field. This is revised yearly, and called the Record of Rights. This cadastral survey and this Domesday Book for so vast a country, executed by the British government, together constitute the largest operation of the kind ever undertaken in any age or country. Thus the government has either conferred *de novo* on the people, or recognised as belonging to them from antiquity, something which is equivalent to property in land, whether such property existed under previous native rule or not, which is sometimes doubtful. This property is attended by transactions of sale, mortgage, trust, loan, security. The land-tax is the first charge on it; but it is rendered valuable by the moderation in the assessment of the tax.

As regards the land-system, there are several tenures, varied by the conditions under which the tax is fixed. The first is that of fee-simple after redemption of the tax, under which government lands are sold to European planters of tea or coffee, and others. The next is that where the tax has been fixed for ever, in Bengal, Bihar, Benares, and part of Madras, and is styled *Zemindari*. The tenure in Orissa, Oudh, Sind, and the Central Provinces is similar, save that there the tax is fixed for twenty or thirty years. Next is the peasant proprietary tenure of the United Provinces and the Punjab, where the tax is fixed for thirty years, and the proprietors are grouped together in their villages as communities or coparcenaries: this is styled *Mouzalwari*. Resembling this in all respects except one is the *Ryotwari* (*Raiyatwari*) tenure of Madras and Bombay—the exception being this, that the Ryot or peasant-proprietor is assessed individually for each field he holds. Similar to this is the tenure in Assam and in Burma. The village organisation is almost everywhere preserved.

Below the land-owners, great and small, are the cultivators. They are divided into two categories, the occupancy tenants and the tenants at will.

The occupancy tenant inherits his tenure, but as a rule cannot sell it without the owner's consent. He is protected by law against exaction and from interference or eviction, so long as he pays the customary or stipulated rent; and generally his rent cannot be increased against his will without a decision of a court of law.

Opium Revenue.—This was for the most part levied on the exportation of the drug to China, but the trade with China has now been ended, and the revenue has greatly decreased; the very small portion consumed in India is taxed under the head of excise. The cultivators of the poppy bring their produce to the government factory, and thence it is sent to the seaport, where it is taken up by the exporters. These arrangements are made to secure the revenue and to prevent illicit consumption.

The *salt-tax* is derived from salt partly obtained on the sea-coast of Madras and Bombay, from the salt lake in Rajputana, from the rock-salt in the Punjab, and imported from England. It is the only tax universally paid by the poor. The rate up to 1901-2 was 2½ rupees per maund (82-2857 lb.); from 1916, 1½ rupees per maund. It was again increased to 2½ rupees per maund in 1923.

Excise.—The farming system which used to prevail in the excise on drugs and spirits, for the manufacture of which the materials are to hand everywhere in superabundance, has been condemned as likely to lead to the encouragement of drinking with a population that is generally temperate. This is being superseded by a better system of central distilleries known as the contract supply system.

Wages and Prices.—Both wages and prices have risen under British rule. In a family the women and children earn some wages. Clothing is scanty and cheap; fuel but little needed, and can be got without payment. Rent for cottages is but little known. The masses of the rural population, however, are not labourers, but live on their lands either as owners or occupants. Incomes from land are not assessed to income-tax. Lastly, there is not, and never has been, anything like a poor-law; nor is there any apparent need for one.

V. FRENCH AND PORTUGUESE INDIA.

French India.—The French had already made several unsuccessful attempts at trading with India, when the *Compagnie des Indes* was formed in 1642-64. In 1668 an expedition of this company took Surat, and established a factory there. In 1672 the French took St Thomé from the Portuguese, but the Dutch drove them out. Pondicherry was acquired in 1674. For subsequent history, see the articles LABOURDONNAIS, CLIVE, DUPLEX, and those on the five establishments that remain French: Chandernagore, Yanaon, Pondicherry, Karikal, and Mahé. French India has an area of 200 sq. m., and a population of 270,000. It has an elected council, and is represented in the French parliament by a senator and a deputy.

Portuguese India has an area of 1600 sq. m., and a population of 600,000. It consists of Goa, Damão, and Diu. See the articles on these, and on Vasco da Gama, Francesco de Almeida, and João de Castro.

VI. THE HISTORY.

Phases of Civilisation.—With a country of 1½ million of sq. m., containing a population of 319 millions, of many languages and nationalities, with traces reaching backwards more than three thousand years—and indeed recent finds in the Punjab and Sind point to a connection with Elam and Sumer in the third millennium B.C.—an historical summary would become an Indian jungle of names and dates unless it were arranged on a plan and guided by some leading ideas. Without such a method no lesson from the facts would be conveyed. Now, in

these days a strange and complex civilisation is perceived in the Indian empire, and the student should inquire by what steps through the ages this has been brought about. At the basis of this immense social fabric is the prehistoric status of aboriginal races. Of these races many an indication is still perceptible, and of them some are still surviving. This status was largely effected by inroads, Dravidian and other, from central Asia, many centuries before the Christian era. From one of these invasions, which was Aryan, sprang the early civilised Hindu or Vedic system. This became overlaid with corruptions, and was reformed by the Buddhistic system some five or six centuries B.C. Then came the Greek invasion under Alexander the Great and some of his successors, which affected only the north-western parts of the country. It was followed by other invasions from central Asia, some styled Bactrian, others Saka or Scythian, which extended much farther than the north-western regions. Meanwhile Buddhism had strengthened and extended itself till it obtained the sovereignty over the whole country. Thus established as a state religion, it lasted for some centuries after the Christian era. Then it gave way to the old Hindu system, revived under an elaborated form which should be styled Brahmanism, and which represents the modern Hinduism. Brahmanism after its re-establishment in the 6th century flourished till the 11th century A.D., when the first Mohammedan invasion took place. This was followed by successive invasions, till the greater part of the country was subdued and parcelled out into various Mohammedan kingdoms. Many of these kingdoms were subdued by one Mohammedan dynasty known as the Mogul. Thus the Mogul empire was established, embracing most parts of the country, in the 15th century. It lasted for less than two centuries, and then began to shrink. Its fall was precipitated by the rise of the Mahrattas, who brought about a revival of Hindu power on the ruins of the Mogul dominion in the 17th century. Meanwhile European influence was beginning to be felt—Portuguese, Dutch, French—all round the coasts, but not far in the interior. This gave way to the British influence, which was established in the middle of the 18th century, and by the middle of the 19th had spread over the length and breadth of the land, being soon afterwards formally proclaimed as the Indian empire. Thus in the India of to-day are to be found traces of (a) an aboriginal condition with some Dravidian civilisation, (b) a civilisation early Hindu or Vedic, (c) Buddhist, (d) Greek, (e) Bactro-Scythian, (f) later Buddhist, (g) Brahmanic or modern Hindu, (h) Mohammedan, (i) Mahratta, (j) continental European, and (k) British. The following summary will briefly indicate the course of events as concerning the several stages in the national life and the development of the mixed civilisation which is seen to-day.

The Aboriginal.—This is prehistoric, and is both without written record and also without coins or inscriptions; but there are philological traces and rude monuments. Roughly, it may be said that there were at least several aboriginal races, and that incursions of tribes from without took place—not, like subsequent invasions, from the north-west, but from various quarters by sea and land. Rude stone monuments are found, and sepulchral remains with primitive implements have been excavated in several parts of the country widely distant from each other. These are of the highest antiquarian interest. They hardly indicate civilisation, but they prove at least a social organisation of a semi-barbaric character. The population was sparse; the face of the country was a primeval

forest, dotted about with cultivation and habitations. The stature of the people was small, the skin dark, and the features of a Tatar cast, with broad cheek-bones, low forehead, nose small, mouth somewhat large. Upon this people, whatever it may have been, two inroads were made, one by a race known as the Kolarian, now represented by the Sonthals, the Bhils, and other tribes; the other, from the north-west, called the Dravidian. The origin of the Dravidians is still doubtful. They must have had some civilisation which spread over the whole country, and which, though absorbed by some subsequent systems in the north, is still traceable in the south. Their race in its ruder form is still represented by hill-tribes—Gonds, Khonds, and others.

The Early Hindu or Vedic.—At least a thousand years B.C.—probably much more, perhaps fifteen hundred—an Aryan race from central Asia descended across the Western Himalayas into northern India through the north-west corner, and gradually spread over the whole country. They were, ethnologically, of the so-called Caucasian type, with fair complexion, straight profile, lofty brow, compressed mouth, tall stature. But their complexion was darkened by sojourn below the Himalayas; their hardihood was softened, while their intellect was refined by the hot climate. They received the name Hindu from Hind, that quarter which they first overran. Their language, the Sanskrit, is one of the most highly elaborated forms of human speech. They brought with them the Vedic religion. They produced the sacred verse of the Vedas and the legends on which the two great epics, the Mahābhārata and the Rāmāyana, were founded in a subsequent century. They formed the rules of social ethics afterwards embodied in a code known as that of Manu, or the moral laws of the Manava priests. They came originally without any divisions of caste, but afterwards their society became broken up into castes, rigidly separated from each other. The first or priestly caste, styled Brahman, was held to have a divine sanction, and was kept separate without intermixture from generation to generation. The two secular castes were those of the soldier (Kshatri) and the trader (Vaisya), including all civil pursuits. These three originally consisted of those who immigrated, but they must have been largely recruited by those whom they found in the country, especially the Dravidians. Below these was the Śūdra or low caste, consisting of aborigines and miscellaneous country-folk. At the bottom of the social scale were the Pariahs, who were outside the pale of caste. The dynastic and territorial arrangements of this era are but slightly known, but there were capital cities on the Ganges near the modern Patna and on the site of Allahabad.

The Buddhist.—As the faith and civilisation above sketched became corrupted and overlaid by mythology, a reformer arose, afterwards known as Buddha, a man of a noble family, in the region near the modern province of Oudh. Though his memory has been shrouded by fable and mysticism, he was a real personality. He lived about 500 B.C. The simplified and purified faith as he left it to his disciples had spread largely but not entirely over India by the year 337 B.C., when the Greeks arrived. Up to this time there are no proper materials for composing history. The Sanskrit language, though preserved as a classic, had ceased to be a spoken language. It had been succeeded by a modified form known as the Pali, which was the chief of the local vernaculars called Prakrit.

By this time Jainism had arisen. It is considered by many to be cognate with Buddhism; at all events it sprang from the same school of specu-

lative thought. It maintained a separate existence on similar if not the same principles, and spread from the western regions, where it first flourished, to other parts of the country. After Buddhism had been banished from the land, Jainism remained, and still continues an effective faith.

The Greek.—Alexander the Great, having invaded India from the north-west corner, penetrated only as far as the Sutlej, and subdued the basin of the Indus and its tributaries—i.e. exactly the modern provinces of the Punjab and Sind. Beyond this his influence was not felt in the main portion of the country. One of his successors, Seleucus, however, entered into relations with Chandra Gupta, a Hindu king of the eastern region, who had not yielded to Buddhism, and whose name was turned into Sandrocottus by the Greeks. For this epoch there are historic materials from Greek sources.

The Bactro-Scythian.—The Greek invasion was succeeded by several invasions of tribes from central Asia. The Bactrians were orientalised Greeks, planted in Balkh or Bactria by Alexander, together with central Asiatic Aryans; of these the records are scanty. The Sakas or Scythians were also Aryans from central Asia. In the absence of records, it is here that numismatics begin to play an important part. Coins have been discovered indicating lines and lives of kings, and dynasties which would otherwise be unknown. These tribes penetrated as far as the central parts of the country, and held their position for some centuries after the Christian era.

The Later Buddhist.—Meanwhile Buddhism had produced some great rulers. In the direct line from the Chandra Gupta already mentioned, there arose As'oka, himself a convert to Buddhism, and the greatest sovereign that ever propagated that faith. He established something approaching to an empire about 230 B.C., his original kingdom being in the lower valley of the Ganges. His general edicts have been preserved. He held several councils, the last of which settled the rule of faith for observance during subsequent centuries. For this era stone inscriptions come into use. Then followed the Bactrian and Scythian invasions already mentioned; but the invaders embraced Buddhism. Thus in a certain sense the several tribes of Aryan invaders became amalgamated, and for some centuries after Christ Buddhism in faith and in civil government prevailed over India. Meanwhile it had spread to neighbouring regions, Ceylon, Burma, Tibet, China, and even Afghanistan. From the visits of Chinese pilgrims recorded on two occasions, separated by considerable intervals of time, much is learned of the then condition of the country. But while the faith endured in those regions, it yielded to the old Hinduism, which should now be called Brahmanism. Before it fell Buddhism raised many architectural monuments in various provinces, which still attest its greatness and culture. Simplicity and purity of faith were its original characteristics, and were probably maintained throughout its Indian career, however much it may have become overlaid by superstition elsewhere. At its best it was probably better than any of the native systems that have succeeded it.

The Brahmanic or Modern Hindu.—The subjugation or suppression of Buddhism may be dated from the time of the Brahmanist king Vikramaditya or Vikramajit, in the 6th century A.D. He overcame the Sakas or Scythians, who it is to be remembered had mostly become Buddhists, expelling some, but amalgamating most of them in his own system. He reigned at Ujjain in the Vindhya region. He antedated, so to speak, his era, placing it back 600 years, or 56 years B.C., and this is the Samvat or modern Hindu era. Thus Brahmanism finally

superseded Buddhism. Its doctrines were expounded by the reformer Sankar Acharya in the Deccan, but it soon became crusted over with fables and inventions. The time of Vikramaditya has in western phrase been termed the Renaissance of Hinduism. Certainly it was so as regards Sanskrit literature. This language, long dead for all matters save religion, was revived for the drama and for descriptive poetry. Kalidasa, of this epoch, is among the sweet singers of the olden time. There were searchings and efforts after knowledge in astronomy, medicine, and other sciences. The caste system may have lost its religious efficacy for some centuries, but it retained its secular vitality. The Brahman caste had held its own. The other castes had absorbed most of the immigrants from central Asia. Then for full four centuries the Brahmanic system was re-established all over the country. It was upheld by Hindu states at Avantipur in Kashmir, at Ajodhya in Oudh, on the coast of Orissa, at Kanouj and Benares on the Ganges, at Delhi on the Jumna, at Surat on the west coast, at Vijayanagar in the southern Deccan, and elsewhere. It produced many splendid fanes, the ruins of which delight the modern observer. It was characterised by a fantastic mythology and a somewhat sensuous idolatry. It produced, in addition to the old code of Manu, a further set of regulations under the name of Yajnavalkya. Minute ceremonial observance, varying for every class, cramped the soul. Thus the spirit of the people was enslaved, their sentiments were cramped, and their thoughts awestruck. Their mind was turned to superstitious requirements rather than to the practical questions of public life. Their society was further enfeebled by the subjection of women. Maternal and conjugal influence must have existed, but in an irresponsible way. Each one of the countless sections of the community, each tribe or class, each cousinhood descending from a common ancestor, within its narrow circle became tenacious of its own traditions, guarding them against all the world, and caring little for anything extraneous. Hence arose the system of village communities, which was consolidated and hardened by the recurring troubles of the time. Each community was a brotherhood within its village only, with cohesion like that of a square of infantry. This institution saved Hindu society during the convulsions of the 11th and succeeding centuries. But a society thus constituted was manifestly a ready prey for northern invaders. During the later part of this era there were apparently some internal revolutions among the Hindus themselves. Then in 1001 A.D. came the Mohammedan invasion. Up to this date of the history of the country not much has been written, in the English language at least; but see *Early History of India—600 B.C. to Mohammedan Conquest*, V. A. Smith (rev. Edwardes, 1924).

The Mohammedan.—In 1001 Mahmud of Ghazni invaded India through the passes of the Suliman Mountains. From this time onwards the history of India can be fully understood from abundant materials, though the details are intricate. Several Mohammedan dynasties in succession established themselves at Delhi, others at Mandu in the Vindhya, at Ahmedabad on the west coast, at five places in the Deccan, of which the two most famous are Golconda and Bijapur. At all these points architectural remains bear witness to culture and power. Thus almost all India fell under Mohammedan dominion. About the year 1200 the Mongol Genghis Khan devastated the north-western part of the country. Succeeding Mongol invasions were repelled by the Indian Mohammedans, but in 1397 the Tatar Timur or Tamerlane advanced to Delhi and proclaimed himself emperor

of India. This title lapsed for a while, till in 1525 his descendant Baber revived it, and became the first who bore the famous title of the Great Mogul. His descendants subdued one by one most of the Mohammedan states in the upper half of India, and became emperors in reality; but the states in the southern half preserved independence more or less. Baber's grandson, Akbar the Great, made this empire effective with the aid of a Hindu minister, Todur Mul. He was perhaps the greatest sovereign that India has ever seen. His code of regulations, the *Ayin-i-Akberi*, is still studied. His reign and the reigns of his three successors were splendid, and their architectural remains evince an artistic culture hardly surpassed in any age or country. Of these three the last was Aurungzebe, a man of masterful ability, disfigured by a cruel bigotry. In his time the empire began to shake, and a new Hindu power was set up—the Marhattas. After his death in 1707, the decline and fall of the Mogul empire set in rapidly. In the general cataclysm which followed four fresh Mohammedan kingdoms rose to the surface—viz. that of the Nawab Wazir of Oudh, that of the Nizam of Hyderabad in the Deccan, that of the Nawab of the Carnatic, that of Hyder Ali and Tippoo at Seringapatam in Mysore. All four are much heard of in the 18th century. After the fall of the empire the titular Great Mogul remained at Delhi till 1857. The Mohammedan system inculcated simplicity of faith and morals. It was bitterly opposed to idolatry, and was at first iconoclastic, but in the end it extended toleration to Hinduism. It fairly respected the landed property and endowments of that religion. It introduced some fresh ideas, and imparted some breadth of ideas generally, and some improved notions of statesmanship and organisation. Otherwise it produced but little effect upon Hindu civilisation. It imposed its own official language and its own criminal law; but it maintained civil laws and customs for the most part. It undertook no public instruction save that which was Moslem. It planted Moslems all about the country, but did not convert the indigenous people in large numbers anywhere except in one quarter. That exception was eastern Bengal, where the inhabitants embraced the Moslem faith; but how this came about is a question not settled. It has been conjectured that Buddhism survived here without caste, and that the inhabitants were not unwilling to adopt Mohammedanism, as a casteless faith. Be this as it may, the eastern Bengal population has multiplied till it amounts to 25 millions, and is the largest Mohammedan people now existing in any one country. Finally, the Mohammedan power endured so long as it was recruited from trans-Himalayan regions and the hardy north: it soon lost its strength when its supporters came to dwell from generation to generation in the hot country below the mountains.

The Marhatta.—The rising of the Marhattas against the Mohammedan domination was begun in 1657 by Sivaji in the Western Ghats. Their dominion advanced as that of the Great Mogul receded. It was a low-caste Hindu confederation, with a hereditary Brahmin chief at its head, under the title of Peshwa, at Poona in the Deccan. Though it absorbed the Mogul empire, it never overcame the four fresh Mohammedan states above mentioned; but it was the principal power existing when the Europeans appeared in force on the scene. It governed its native Deccan territories tolerably well; and to the north of them it founded several states which still endure prosperously. Still, it had less civilisation than any power since the Vedic-Aryan invasion, and it threw many parts of the country into confusion. Under

its shadow some fresh evils sprung up, such as Thuggee and the organised bandit system known as Pindarry. During this hapless time occurred irruptions under the Persian Nadir Shah and the Afghan Ahmed Shah; but these invaders came, slew, sacked, devastated—and turned back again without permanently affecting the country. In the overthrow of the Mogul power that ensued, there arose a fresh system in the Punjab—viz. the Sikh. A prophet arose named Baba Nanak, who preached a reformation of Hinduism. He was followed by Govind Singh, who established the system by force of arms in the Punjab, and even as far as the Jumna. Thence arose a Sikh dynasty, which lasted till the middle of the 19th century. This essentially Hindu power cut off the Indian Mohanmedans from what had been their original base in Afghanistan, and left them isolated amidst their foes.

The Continental European.—In the time of the Moguls and the Mahrattas several European nationalities appeared in India as travellers, traders, missionaries. The Dutch had several settlements, of which the memory still remains. The Portuguese, after the discoveries of Vasco da Gama, controlled virtually the whole west coast, excepting Bombay, then a small place. Their headquarters were at Goa, on the coast south of Bombay, which became a town and a harbour of the first rank in the 18th century. The Portuguese influence affected civilisation in the western region to a perceptible degree. In the 18th century the position of the French rivalled that of the English; the wars between the two nations were carried into the East, and the contest was waged on the waters as well as on the land of India. The name of the great Frenchman Dupleix is respected by the British in India as of the worthiest of foemen. Thus the British had to contend simultaneously with French rivals as well as native enemies on Indian soil.

The British.—This begins to be a dominating influence from the battle of Plassey in 1757, won by Clive over the Mogul, which gave to England the dominion of Bengal and Behar, the most populous provinces in the whole country. The British East India Company had been settled in India since 1653. It had three trading settlements on or near the coast at Calcutta, Madras, and Bombay. These grew into establishments for fighting and governing, and the territorial nucleus thus formed soon expanded. The acquisition of Bengal with Behar raised the company's territories into a dominion of magnitude. Thus the company in the later half of the eighteenth century appeared as one of the powers. It really rose on the ruins of the Mahratta dominion. Within sixty years from Plassey, that is by 1818, when Poona, under the last of the Peshwas, fell to the British, the East India Company was the master of India as far as the Indus basin, but not in the Punjab nor in Sind. Within these limits it had acquired the whole basin of the Ganges and the coast districts on both sides of the peninsula. The Great Mogul, now powerless, was under its care at Delhi. It had conquered the Mohammedan state in Mysore and restored a Hindu sovereign there. The two Mohammedan states of Oudh and Hyderabad (Deccan) were its dependent allies, though with all honour. It was maintaining many native states, Hindu and Mahratta, in the same position. Among these must be included (after severe fighting) Nepal, the one Himalayan state which was capable of waging war, and which had contended sturdily with British forces. The Pindarries, who raised a robber-organisation almost to the rank of a power, had been subdued. The British dominion had been founded by Clive, preserved during a world-wide crisis for England by Warren Hastings,

extended by Cornwallis, and still further advanced by Wellesley, and almost perfected by the Marquis of Hastings. By 1828 there was a Pax Britannica throughout India after centuries of internal war and revolution. How far the East India Company was the aggressor in any of these transactions may be a controversial question. It was often induced to participate in the contests of the native states among themselves; in self-defence it had to fight the combinations formed against its very existence; and being the victor, it had to deal with the vanquished. Thus by various means the fabric of its dominion rose. It had raised a large native army and some European forces of its own, but these had to be sustained by royal troops from England; consequently on each renewal of its charter the company passed more and more under the control of the British government. The next imperial step was in 1825, when the first Burmese war occurred under Amherst; it ended in some acquisition of territory, which was the beginning of a new dominion across the waters of the Bay of Bengal. There was then a development of peaceful civilisation under Lord William Bentinck till 1835. But in 1838 it was decided to set up a native sovereign in Afghanistan under British protection, as a means of guarding the north-western frontier. This led to the first Afghan war, after which the British evacuated that country. This was the first check in a victorious career of eighty years since Plassey. There remained the basin of the Indus yet unconquered—i.e. Sind and the Punjab; the former was conquered under Ellenborough, the latter under Hardinge and Dalhousie after severe fighting in two wars, in which the Sikhs were the aggressors. Thus the Sikh kingdom so ably founded by Ranjit Singh succumbed. Then at length it was said that not a shot could be fired in anger throughout India without leave of the British government. Under Dalhousie also a second war broke out with the Burmese; the result extended British dominion over the delta of the Irawadi. At this time all the works of peace, moral and material, were prosecuted. Shortly after Dalhousie had handed over his charge to Canning the mutiny in the Bengal native army broke out in 1857.

A crisis arose of which the dimensions can readily be gauged by the reader who has followed the various facts already set forth in this article. After the occurrence of some isolated mutinies in the Bengal native soldiery, generally called sepoys, during the early part of 1857, the native portion of the garrison at Meerut, near Delhi, broke out on 10th May; the European garrison failed to prevent them, and the mutineers marched straightway to Delhi, and were joined by the native troops there and by the city mob. The rebels set up as emperor the titular Great Mogul, who dwelt in the ancestral palace there under British protection, and proclaimed the restoration of the Mogul empire. This event was rapidly followed by the revolt of almost the whole native army of the Bengal Presidency. Their comrades of the Bombay Presidency were but slightly affected, and those of Madras hardly at all. At that time the native forces numbered more than 247,000 men of all arms; of these about 50,000 belonged to Madras, 30,000 to Bombay, and the remainder to Bengal; among the latter, however, were many troops called irregular. A large part of the irregular troops remained staunch; but of the Bengal regular troops only seven battalions continued in service. From 80,000 to 90,000 soldiers, horse and foot, were in revolt, having in many cases murdered their officers, and sometimes the European families also. The mutineers, too, who were cantoned over many stations in broad provinces, held forts, arsenals, treasuries. They were armed with British weapons, had been

organised with British discipline, were in possession of much artillery, of a great number of cavalry horses and other transport, and of vast sums of treasure. In Hindustan, in Oudh, and in parts of Malwa, throughout the summer the British power was insulated at certain points, such as the camp before Delhi, the cantonment at Meerut, the fortresses at Agra and Allahabad, the weak fortifications at Lucknow. Elsewhere the European magistracy with their families had been either killed or hunted away, and the court-houses with their records burnt. The disaster extended over at least an area of 100,000 sq. m., with a population of 40 millions. It occurred, too, at the worst season of the year. If not speedily stamped out the fire must spread over the whole country. The year was a centenary of historic events. It was just one hundred years since Clive founded British dominion at Plassey, and two hundred since Sivaji the Mahratta struck a deadly blow at the Moslem power. Many an enemy thought that the knell of the empire had sounded. And certainly, unless the resources of the British Isles could be brought to bear upon the scene of revolt within a few months, the British authority would be narrowed to its three original seats—namely, the presidency towns resting on the sea-board.

At that time there were 40,000 European troops in the country. Several thousand men on their way from England to China at Lord Elgin's disposal were, with his co-operation, diverted to India. Some 40,000 European soldiers were despatched from England round the Cape of Good Hope by a sea-voyage of 12,000 miles. Meanwhile the disasters at Cawnpore and elsewhere in Hindustan had been partially retrieved by Henry Havelock. At the outset a force, largely consisting of Europeans, marched against Delhi. After a severe siege of four months, the place was recaptured by assault. The communications had been maintained continuously with the Punjab, under John Lawrence, as a base whence reinforcements were derived. Native troops were raised from the loyal Punjab in place of the mutineers of Hindustan. Lucknow, for a long while after the death of Henry Lawrence besieged by rebels, was first relieved and afterwards recaptured by a European force under Colin Campbell. The districts were speedily reoccupied by British authority. Though many influential individuals, some chiefs and princes, and some classes, including the worst part of the mob, had joined the rebellion, or rather the military revolt, still the mass of the people in these districts had remained passive, and readily returned to their allegiance. The principal native princes and their states had set an important example of loyalty. Within six months of the outbreak the imperial danger was surmounted, though troubles lasted here and there, and the embers smouldered for more than a year, especially in the hilly parts of the central regions. The cost of suppressing this rebellion is reckoned at 40 millions sterling. Unlike all the earlier foreign dynasties, the British power had never been naturalised or domesticated in the country, but was then, as ever, recruited constantly from the British Isles. Its officers serving in the country had been born and educated in Europe, and possessed as a reserve against danger all the imperial qualities of their race.

Many causes were assigned for the Indian mutiny. The greased cartridges served out to some of the Bengal troops operated as an immediate provocation. The Brahmins were too numerous in the ranks; they were fanatical, and they had the brains to contrive mischief when discontented. The Kabul disaster had broken the spell of invincibility. Certain chiefs near the scene of the outbreak were labouring under a sense of wrong, real

or supposed. Some native states had been alarmed at British policy with regard to the right of adoption. The annexation of Oudh, however righteous in itself, had induced many Mohammedan conspirators to excite mutiny, and to turn it to political account. This brought about a very unusual combination between Mohammedans and Hindus. Still, these and other lesser causes would never by themselves have brought about such a crisis as that which has been described. The prime, the fundamental cause was a large and simple fact, namely this. The native forces were much too large relatively to the European. There was only one European soldier to six native soldiers, whereas now there is one to two. The sepoys then had the physical force in their hands, and they knew it. The distribution, too, of these excessive numbers aggravated the peril. The sepoys were, as already seen, in charge of the stations containing the state resources, civil as well as military. It was the sense of power which gave them the mind to revolt. Their interests, including employment, pay, pension, and the like, were indeed bound up with the British rule. The government was over-slow to believe that the men would revolt to the destruction of their own prospects. But their conduct proves that there are moments when religious fanaticism, national sentiment, pride, and passion will prevail over self-interest. The occurrence was only a question of time, and many will wonder why it did not happen before. But an analysis of historic circumstances would show that never before had a complete opportunity offered. Mutiny of particular bodies of troops had often occurred already, and had been overcome. Thus the British authorities came to be insufficiently alive to the symptoms which portended the events of 1857. But after the storm had burst they evinced qualities rarely surpassed in the annals of the nation, and the history of the time is aglow with genius, valour, and capacity.

The crisis past, no time was lost in rectifying the military faults which had rendered the revolt possible. The native troops were reduced in number, the European troops were augmented. The physical predominance at all strategic points was placed in the hands of European soldiers, and almost the whole of the artillery was manned by European gunners.

Peace and order having been restored to the empire in 1858, various changes, constitutional and other, were made. The East India Company, the greatest corporation ever known to history, ceased to exist, and the government was assumed by the British crown. The army was reorganised so as to guard against the danger from which the country had just been saved. As compared with the relative proportions of former times, the European force was doubled, while the native force was reduced by more than one-third. Thus, as already seen, the European and the natives were as one to two; moreover, the European was placed in charge of the strategic and dominant position, so that the physical power was now in his hands. The dominion was consolidated by the work of peace under successive viceroys, Elgin, Lawrence, Mayo, Northbrook, with material improvement and moral progress. In 1878, under Lytton, a second Afghan war was waged, which led to the strengthening of the north-western frontier. The work of peace was continued under Ripon till 1884, when, under Dufferin, it became necessary to proceed against the king of Ava, and subsequently to annex Upper Burma. The years 1896-1905, under Lord Elgin and Lord Curzon, saw famine, plague, earthquakes in Assam, the reorganisation of the army by Lord Kitchener, and the successful mission to Tibet. In 1899-1905 the Indian revenue increased

from £68,500,000 to £84,700,000, and commerce and industry had correspondingly developed. The partition of Bengal (q.v.) led to much discontent and agitation amongst the Bengal Hindus; a 'Swadeshi' movement sought to boycott European manufactures in Lord Minto's viceroyalty (1905-10); and hostility (under the guidance of educated natives) having taken aggressive forms, accompanied by assassination and bomb-throwing, an explosives act and a stricter press law were passed in June 1908. In November 1911 the king and queen visited India, and held the coronation durbar at Delhi on 12th December. At the close of the durbar the king announced the transfer of the seat of the government of India from Calcutta to Delhi, the creation of a governorship of Bengal, and of a new lieutenant-governorship of Bihar and Orissa. This latter announcement involved the reversal of the partition of Bengal and the disappearance of Eastern Bengal and Assam as a separate province. India contributed freely in men and money in the war, and was represented among the imperial delegates at the Peace Conference as well as at the Imperial Conference and the Imperial Cabinet.

On 20th August 1917, a declaration made in the House of Commons laid down as the goal of British rule in India the progressive realisation of responsible government of the kind enjoyed by the self-governing dominions. The reforms of 1919 provided the first step towards the attainment of this goal, and the association of India with other parts of the empire in the Imperial Conferences, the signature of the Peace Treaty by representatives of the government of India, and the admission of India as an original member of the League of Nations, are indications of the recent great advance of India in international affairs.

For history, see *The Cambridge History of India*, ed. Prof. E. J. Rapson (1922 *et seq.*), the great works by Mill and Thornton, and the shorter one by Marshman; for special periods, Mountstuart Elphinstone, for the Mogul era; Keene, for the decline and fall of the Mogul empire; Grant-Duff, for the Marhattas; Malletson, for the French in India; Kaye, for the first Afghan war; Kaye and Malletson, for the Mutiny; Trotter and Maine, for the Victorian era. Much light is derivable from the biographies of Clive, Warren Hastings, Metcalfe, Macaulay, the Lawrences (Henry and John), Mayo, and Dalhousie. There are histories of India from the earliest times by Trotter (1890), Talboys Wheeler (1891), H. G. Keene (1893), and Vincent Smith (1919); of Ancient India, by Romesh Chunder (3 vols. 1889-91), Vincent Smith (revised by S. M. Edwardes, 1924); of the British Dominion in India, by Sir A. Lyall (3d ed. 1894); of the Portuguese in India, by Danvers (1894); a series of 'Epochs of Indian History,' edited by J. Adams; and valuable papers on the Indian Mutiny, selected by G. W. Forrest. See also the *Imperial Gazetteer of India* (3d ed. 1907-9); government reports on moral and material progress; and the statistics published by the India Office. The *Journal of the Royal Asiatic Society* and the *Calcutta Review* supply quite a mine of materials. Some light is thrown by Tod's *Rajasthan*, Rajendralal Mitra's *Antiquities of Orissa*; Lyall's *Asiatic Studies* (2d ed. 1884), Edward Thomas's numismatic essays, and Ferguson's *History of Indian Architecture*. Indian architecture is illustrated at the articles on Agra, Benares, Elephanta, Ellora, &c. And see articles on religions, persons, places, &c., in this work.

India, STAR OF. See INDIAN ORDERS.

Indiana, popularly known as 'the Hoosier State,' is the thirty-seventh state of the American Union in area, and the eleventh in population, and is centrally situated between 37° 47' and 41° 50' N. lat., and 84° 49' and 88° 2' W. long. It is bounded on the N. by Lake Michigan and Michigan state, on the E. by Ohio, on the S. by Kentucky, from which it is separated by the Ohio River, and on the W. by Illinois, the Wabash River being the line of division a part of the way. Its greatest length north and south is 276 miles, its average breadth

140 miles, and its area 36,350 sq. m. The coastline on Lake Michigan is about 60 miles.

The surface of the country has a slight slope towards the west and south-west, the highest point, near the eastern boundary, being 1250 feet above sea-level. Drainage is in four main directions: through the St Joseph River to Lake Michigan, the Maumee River to Lake Erie, the Kankakee River to the Mississippi, and the Wabash and other streams to the Ohio; small streams intersect the state in every direction, and in the northern part there are numerous small lakes. The northern half of the state is generally level, except for occasional irregular ridges forming 'divides' between streams. Hills increase in frequency from the centre of the state to the south and south-east, and along the Ohio 'knobs' 200-500 feet high are almost continuous, with deep gorges and river-bottoms between. Much of the north-western regions is inundated with water the greater part of every year; but this land is being actively reclaimed by a system of drainage. The fertility of the soil, whether clay or sandy loam, is greatly increased by a vast system of under-draining, which has been very successful. Returns show that about 91·2 per cent. of the land area in 1920 was in farms.

The minerals include coal, bog and hematite iron ores, and stratified limestones and sandstones in abundance, ochre-beds, kaolin, fireclays, and some gold. The actual workable coalfield covers an area of 6000 sq. m. The production of coal of all kinds amounted in 1830 to 1,500,000 tons, in 1901 to 7,000,000 tons, and in 1921 to 20,000,000 tons, mostly block coal, although there is also abundance of bituminous and some cannel coal. The natural-gas field, the centre of which is in Delaware county, 40 miles N.E. of Indianapolis, has been developed since 1886. The yield is one of the largest in the world, though the decreasing pressure indicates a coming exhaustion. A large quantity of it is transported to Chicago. In the gas region, and in the districts within reach of its pipes, it became for a time almost the only fuel. Petroleum is one of the most valuable products of Indiana, though the annual production is insignificant compared with that of the neighbouring state of Illinois. Another valuable product is Portland cement, Indiana's supply of limestone being practically inexhaustible. Other mineral products are coal-tar, oil-stones, pyrites, fire, brick, and potter's clays, kaolin, and good sandstone. The climate is healthy but variable; the winter is severe but short, the summer hot.

The principal industry is agriculture, the chief crops being maize, wheat, oats, rye, barley, buckwheat, hay, potatoes, and tobacco. Of live-stock swine and cattle are the most numerous. There are many sheep also, the wool clip being 3,000,000 or 4,000,000 pounds. Recently the production of tomatoes for canning has received much attention. Flax and sorghum are raised, as are also enormous quantities of apples and peaches. Dairy-produce is exported. Honey, maple-sugar, cider, and vinegar are made, and fruit and vegetables are preserved.

The manufactures of Indiana present great variety, and are often important. Among the largest manufactories of their class in the world are the automobile and plough factories at South Bend, and there are numerous and extensive manufactories in Indianapolis and other cities, the chief industries being flour and grist-mill produce, agricultural implements, woollen goods, iron-ware, machinery, automobiles, lumber, leather, boots, shoes, and clothing. Pork-packing, centred at Indianapolis, is a large and important industry. Indiana turns out much furniture, largely made from the valuable timbers of the Wabash and its tributaries. The wood-pulp industry

has also become important. The abundance of natural gas available as fuel has attracted many manufacturing of iron and steel, which are now among the most important in the state. Flour-milling is also extensively carried on, and printing and publishing and the manufacture of fireclay products deserve mention. The trade is almost wholly internal, though Michigan City has trade with Canada; navigable rivers and canals greatly facilitate commerce. The central portion of Indiana compels all main through-lines from the east and west to cross the state. In 1880 there were 4020 miles of railway in operation; in 1901, 6500 miles; in 1922, 10,800 miles (steam and electric), affording such facilities that the Wabash and Erie Canal, and the White Water Canal from Lawrenceburg to Hayestown, have been superseded and abandoned. The Ohio is navigable throughout its length within the state; the Wabash is navigable to Lafayette, and its branch, the White River, for about 60 miles.

The population in 1800 numbered 4577 whites and 163 coloured, 135 of the latter being slaves. In 1860 the population was 1,350,428; in 1910, 2,700,876; in 1920, 2,930,390. The cities with over 50,000 population in 1920 were Indianapolis (314,194), Fort Wayne (86,549), Evansville (85,264), South Bend (70,983), Terre Haute (66,083), and Gary (55,378). Great care is devoted to education, which is compulsory from 7 to 14 years (16 if unemployed). The number of teachers is about 20,000. There are about 800 high schools and many institutions of a collegiate character. There are a state university at Bloomington, the Purdue University at Lafayette, state normal schools at Terre Haute and Indianapolis, and a normal college at Covington. In addition are several private normal schools and schools of law, medicine, and theology; also various charitable institutions. In most of the colleges, as in the common schools, the sexes are educated together.

The state is divided into ninety-two counties. The governor is elected for four years. The general assembly, composed of fifty senators and one hundred representatives, meets every two years. Indiana has two senators and thirteen representatives in congress. The judges of the supreme court, five in number, are elected for six years.

History.—Indiana was discovered by La Salle in 1671, and constituted part of New France. In 1763 France ceded the country to Great Britain: by the treaty of 1783 it became a part of the United States, under the general term of the north-west territory, which later was divided into the territories of Ohio, Indiana, Michigan, Wisconsin, and Illinois. In 1816 Indiana was admitted to the Union, and the state government was finally settled at Indianapolis in 1825. By the ordinance of 1787 slavery was prohibited in the territory. The Indian troubles resulting from the influx of settlers culminated in the battle of Tippecanoe (see HARRISON, W. H.) in 1811. Indiana supplied five regiments for the war with Mexico, and during the civil war furnished for the government service 208,367 men, of whom 24,416 were killed or died of disease.

Indianapolis, the capital and largest city of Indiana, is on the west fork of White River, on a level plain, near the centre of the state, 195 miles SSE. of Chicago by rail. It is a regularly-built and beautiful city. Its streets, many of them 100 feet wide, for the most part cross at right angles; but four main avenues, radiating from a central park, cross the others diagonally. There are in Indianapolis a handsome state capitol, the federal building, university, art school and museum and other colleges, state-house, fine court-house, city hall, public library, asylums for the insane, the blind,

and the deaf and dumb; and the city possesses an imposing monument to the soldiers and sailors who fell in the civil war. Indianapolis is one of the chief railway centres of the United States, fifteen main lines converging there. The trade in agricultural produce is very extensive. Pork-packing is the leading industry, but there are also large flour and cotton and woollen mills, numerous foundries, and manufactories of furniture, carriages, tiles, &c. (see INDIANA). The site of Indianapolis, then covered with dense forest, was selected for the future capital in 1820, and the city was founded in 1821. In 1860 the pop. was 18,113; (1870) 48,244; (1880) 75,056; (1890) 105,436; (1900) 169,164; (1910) 233,650; (1920) 314,194.

Indian Ocean. The Indian Ocean is bounded on the W. by Africa, on the N. by Asia, on the E. by Australia and the Australasian Islands. According to modern geographers it is limited to the S. by the 40th parallel of south latitude, in which region it opens widely into the Southern and Antarctic oceans. It gradually narrows towards the north, and is divided by the Indian peninsula into the Bay of Bengal on the east and the Arabian Sea on the west, the latter sending northward two arms, the Persian Gulf and the Red Sea. Within these limits the Indian Ocean is estimated to have an area of 19,347,000 sq. m.

At the dawn of history the Indian Ocean was known as the Erythraean Sea; the Phœnicians are said to have been familiar with this southern ocean at a very early date. Necho, an Egyptian monarch who flourished about 610 B.C., is reported by Herodotus to have sent some of his vessels, manned by Phœnicians, into the Erythraean Sea with orders to return by the south of Africa and the Columns of Hercules. Whether or not this voyage ever took place, it appears certain, from their reports as to the position of the sun to the north of them, that these early navigators penetrated far south (see the article GEOGRAPHY). From a very early date there was a coasting trade between India and the Persian Gulf, but the voyage of Nearchus, one of Alexander's generals, from the Indus to the Persian Gulf, is the earliest reliable record of these coasts. Hippalus, an Egyptian navigator who flourished about the beginning of the Christian era, was the first to observe the regular alternations in the direction of the monsoons of the Indian Ocean, and to profit by them to open up a direct route across the high seas from the Red Sea to India. The shore routes were henceforth abandoned, and a fresh impulse was given to voyages into oriental waters. In the 9th century the Arabs made frequent voyages across the Indian Ocean, Soleiman of Siraf being probably the first to cross the Bay of Bengal and pass into the China Sea. In 1486 the Portuguese rounded the Cape of Good Hope, and in 1498 Vasco da Gama reached the coasts of India by the same route. In 1521 the one remaining ship of Magellan's squadron crossed the southern Indian Ocean in completing the first circumnavigation of the world.

The mean depth of the Indian Ocean is estimated at about 2300 fathoms, or slightly greater than that of the Atlantic (q.v.). The greatest depths are in the eastern part to the south of the equator, where

INDO-CHINA

English Miles
0 50 100 150 200 250
Kilometres
0 50 100 150 200 250

it is estimated that there are about 1,185,000 sq. m. with a depth of over 3000 fathoms. Over 12,000,000 sq. m. of this ocean's floor lie between the depths of 2000 and 3000 fathoms.

The area of land draining into the Indian Ocean is estimated at 6,813,600 sq. m., and the annual rainfall on this land is equal to 4379 cubic miles of water. The rivers flowing from the Asiatic continent are by far the most important, and they carry an immense amount of detrital matter into the Bay of Bengal and Arabian Sea, these forming extensive deposits of blue mud. Along the African coasts, in depths from 100 to 1000 fathoms, there are great deposits of glauconitic sands and muds, and on these as well as other coasts there are coral muds and sands, and blue and green muds in the shallower depths. In the deeper parts of the ocean, far from land, there are vast deposits of red clay, Radiolarian ooze, and Globigerina ooze. In the Southern Ocean, towards the Antarctic, the bed of the ocean is covered with a Diatom ooze.

The temperature of the surface waters of the Indian Ocean varies much in different parts of the ocean, and at the same place at different times of the year or states of the wind. In tropical regions the temperature usually varies from 70° to 80° F., and the yearly range is only 7° or 8° F. Off the Cape of Good Hope and off Cape Guardafui, however, the annual range of temperature may be from 20° to 30° F. For instance, sudden and great changes of temperature are often noticed off Cape Guardafui when the wind blows off shore, for in this way cold and deep water is drawn up along the African coast to take the place of the warm surface water which is driven eastward by the wind.

The temperature of the water at the bottom of the Indian Ocean is very uniform and subject to little, if any, annual variation. In the Bay of Bengal and Arabian Sea temperatures of 33°·7 F. and 34°·2 F. have been recorded at the bottom; these are not more than the fraction of a degree higher than those observed by the *Challenger* in 50° of south latitude. It is certain, therefore, that this deep cold water is slowly drawn into the Indian Ocean from the Antarctic to supply the place of the warm surface currents that are driven southward by the winds. The currents of the Indian Ocean are less constant than in the other great oceans, and are largely controlled by the direction and strength of the monsoons (see MONSOONS). Some of the most characteristic coral atolls and islands are to be found towards the central part of the Indian Ocean, such as the great Maldivé group, the Chagos, Diego Garcia, and the Cocos Islands. Almost all the tropical shores are skirted by fringing and barrier reefs. Christmas Island is an upraised coral formation. St Paul's, Mauritius, Rodriguez, and others are of volcanic origin; while Madagascar, Ceylon, and Socotra are typical continental islands.

Indian Orders. Three British orders of knighthood take their name from India. (1) The Imperial Order of the Crown of India, instituted 1st January 1878, consists of the Queen, certain princesses of the royal house, of numerous native Indian princesses, and the wives and other female relatives of the viceroy of India, the governors of Madras and Bombay, the Principal Secretary of State for India, and the Commander-in-chief in India. (2) The Most Exalted Order of the Star of India, instituted in 1861, and enlarged from time to time, consists of the sovereign, a grandmaster (the viceroy), Knights Grand Commanders (G.C.S.I.), Knights Commanders (K.C.S.I.), and Companions (C.S.I.). The badge is a light-blue ribbon with thin white stripes, and the motto, 'Heaven's Light our Guide.' (3) The Most Eminent

Order of the Indian Empire, instituted in 1878 to commemorate the proclamation of Queen Victoria as Empress of India, and enlarged at various times, consists of the sovereign, a grandmaster (the viceroy), Knights Grand Commanders (G.C.I.E.), Knights Commanders (K.C.I.E.), and Companions (C.I.E.). The motto of the order is *Imperatricis Auspiciis* ('Under the favour of the Empress').

Indian Poke. See HELLEBORE.

Indian Red, a silicate of iron, imported from the Persian Gulf.

Indians, RED. See AMERICAN INDIANS.

Indian Shot. See CANNA.

Indian Territory, a region of the United States forming part of the Louisiana Purchase of 1803, and set aside in 1832 as a place of residence for the Indian tribes of the southern states. The western half of this region was organised into Oklahoma Territory in 1889, and in 1907 the two territories were united into the present state of Oklahoma. For description, see OKLAHOMA.

Indian Tobacco. See LOBELIA.

Indian Turnip. See ARUM.

India-rubber, CAOUTCHOUC, or GUM ELASTIC, extensively used in the arts, on account of its elasticity and flexibility, its insolubility in water, and its great impenetrability to gases and fluids in general, is found in the milky juices of plants, and most abundantly in the natural orders Moraceæ, Artocarpaceæ, Euphorbiaceæ, Apocynaceæ, and Asclepiadaceæ. It exists in the milky juice of plants growing in temperate climates; but, as the quantity is small and the amount of resin too great, it is only in tropical and subtropical countries that it occurs so abundantly as to be of economical importance. The principal South American tree is the Euphorbiaceous *Hevea brasiliensis*. *H. guianensis*, also called *Siphonia elastica* or *Jatropha elastica*, is inferior. The Mexican *Castilloa elastica* is Artocarpaceous. In the East the *Ficus elastica* (of the order Moraceæ), akin to the Banyan (q.v.), is a tree of noble proportions, the appearance of whose glossy leaves is well known in Europe from small specimens grown in pots as ornamental plants. Various Apocynaceous trees (Willughbeia, Landolphia, Ureola, &c.) yield commercial quantities of rubber in Malaya, Borneo, and Central Africa. Many wild rubbers produce a caoutchouc which is too resinous even to mix with a good quality.

Balls made by the Haytians of the gum of a tree, bouncing better than the wind-balls of Castile, are mentioned by Herrera in his account of Columbus's second voyage. In 1615 Juan de Torquemada mentions the tree which yields it in Mexico, describes the mode of collecting the gum, and states that it is made into shoes; also that the Spaniards use it for waxing their canvas cloaks to make them resist water. More exact information was furnished by M. de la Condamine in 1735. As 'rubber,' for rubbing out black-lead pencil marks, it was imported into Britain in small quantities at the end of the 18th century, and sold at 3s. the cubic half-inch. Flexible tubes for the use of surgeons and chemists had been made of it; but it was not till after 1820 that the manufacture of waterproof cloth first gave it commercial importance. About the same time a method was discovered of fabricating articles by casting india-rubber in moulds.

More than half of the world's supply used to come from Brazil. Large quantities come also from Ceylon, India, Java, the Federated Malay States, Peru, Bolivia, Guiana, and from various parts of Africa, especially Belgian Congo and West Africa. Up to about 1910 the world's supply of rubber was obtained chiefly from wild rubbers, but since that time plantation rubbers have greatly exceeded

wild, though these have not seriously diminished. The popularity of bicycles and motor-cars, requiring large quantities of rubber for their pneumatic tires; the advance of electrical industries, in which it is valuable as a non-conductor; and innumerable other new applications, as in rubber-cored golf-balls and vulcanite fountain-pens, have caused an enormous increase in the importation of rubber.

India-rubber is sometimes collected by cutting the trees down (a ruinous process), but usually by making simple incisions in the trunks. In a few hours the milky juice dropping from the cuts fills tin cups which are fixed to the tree by means of clay. The sap, or latex, as it is called, is not coagulated as it collects, but may be preserved by the addition of 3 per cent. of ammonia until the collection is completed. A good tree will yield four ounces of juice daily, and twenty gallons in a season; frequent tapping, if carefully performed, does not appear to cause much injury to the trees. The average amount of rubber collected in one season varies between 200 lb. and 450 lb. per acre. Fine qualities of rubber are often injured by adulteration and careless collecting.

In order to separate the caoutchouc different methods are adopted. That which is considered the best is used on the Amazon for the preparation of Pará rubber, and consists of dipping a paddle in the latex, then holding the wet blade over a specially prepared smoky fire and turning so as to dry both sides equally. The paddle with its thin coat of rubber is again dipped and dried, this process being repeated until the rubber 'biscuit,' as it is termed, weighs about 10 lb. In other methods of coagulation, the evaporation of the water is obtained by natural warm air or by the heat of the native operator's body. Creaming, churning, and chemical methods also have many adherents. Among recently employed chemicals are dilute acetic, sulphuric, and hydrofluoric acids, mercuric chloride, formalin, and common salt; and electrolytic separation of the caoutchouc is now in use. The latex which is used for Pará rubber contains from 30 to 40 per cent. of caoutchouc, and the dried rubber on being washed previous to manufacture loses from 15 to 20 per cent. of its weight; the loss in weight from other varieties ranges from 10 to 50 per cent.

Pará india-rubber is the best, and commands the highest price. Unvulcanised india-rubber is a tough, fibrous substance, possessing elastic properties in the highest degree. When cooled to the melting-point of ice (32° F.) it hardens, and in greater part, if not entirely, loses its elasticity, but does not become brittle. When heated to the boiling-point of water it softens and becomes much more elastic than at ordinary temperature. It is insoluble in water and alcohol, is not readily acted upon by alkalis or acids, except when these are concentrated or heat is applied, but is soluble in ether, chloroform, bisulphide of carbon, naphtha, petroleum, benzol, and the essential oils of turpentine, lavender, and sassafras. Many other essential and fixed oils, when heated with rubber, cause it to soften, and produce thick glutinous compounds, especially linseed-oil, which, in the proportion of 1½ lb. of the oil to 4 oz. of rubber in thin strips of films, yields a solution which, when strained, is of great use in rendering shoes, cloth, &c. waterproof. Rubber begins to melt at about 250° F., and if cooled in thin layers again hardens. If stronger heat is applied the oily mass which results does not harden on cooling. At 600° F. it is completely decomposed, and by dry distillation yields a highly complex liquid, the chief constituent of which is caoutchene or dipentene; this substance possesses great solvent powers over india-rubber and other substances.

To soften and purify the raw material it is boiled for some time in large tanks. It is then put through powerful machines which masticate and reduce it to shreds, and while undergoing this operation a stream of water is constantly running over it and thoroughly cleansing it from all impurities. It is then rolled out into thin sheets and hung up to dry in a room heated by artificial means, and thus freed from all moisture. Or, after cleansing, the material undergoes a process of kneading under very heavy rollers, which causes the adhesion of the various pieces of rubber to each other, and ultimately yields a mass or block of rubber in which the condensation is so perfect that all air-holes and other cells and interstices disappear. The block of rubber is then cut under water by powerful knives or shears into sheets, from which bands or threads may be obtained. In the manufacture of square threads cutting only is had recourse to; and the delicacy of the operation may be understood when it is stated that one pound of rubber will yield 32,000 yards of thread. The round elastic thread is prepared from rubber which has been treated with about double its weight of bisulphide of carbon, containing about 5 per cent. of alcohol, which yields a soft material resembling in consistence bread-dough or putty; and this, being squeezed through a series of small holes, produces minute round threads, which are first received on an endless piece of velvet, and ultimately on an endless web of common cloth 500 to 600 yards long. During the transit of the threads across this the solvent evaporates, and leaves the india-rubber. When it is wished to weave these threads into cloth they are wound upon bobbins, care being taken to stretch the rubber as much as possible, so as to deprive it for the time being of its elasticity; and after it has been woven into the cloth, a hot iron is passed over the fabric, and immediately the rubber resumes its elasticity.

The method for making waterproof clothing or 'mackintoshes,' the first application of rubber on a large scale, suggested by Professor Syme in 1818, was patented in 1823 by Charles Macintosh of Glasgow. Dissolved in naphtha or other solvent it is amalgamated with other ingredients according to the nature of the material it has to be applied to. It is next spread on the surface of the cloth, a process formerly done by hand, but now by means of spreading-machines, which apply it in very thin coats—so thin that with pure Pará proofing as many as twelve coats are spread to make the cloth air-proof, but so thin is each coat that the twelve only measure one ninety-sixth part of an inch; for ordinary waterproof purposes, however, five or six are generally sufficient. For double textures the cloths are then pressed together between heavy rollers. These cloths are all vulcanised, and this can be performed by a number of processes—by the 'cold' process, by vaporising, by steam, and by dry heat. The garments are then cut out from the cloth, and fastened together by means of pure rubber cement, which makes the edges adhere. Rubber latex, however, can now be shipped in a liquid state, and it can be used directly to impregnate a cotton fabric, in tire-making, for example. Raw latex can also be used in paper-making.

Vulcanised India-rubber.—Pure india-rubber is now used only to a limited extent in the arts, but it is applied in the vulcanised state to a very large extent. The remarkable change which caoutchouc undergoes when mixed with sulphur and heated, according to circumstances, from 240° to 310° F., was discovered by Charles Goodyear, in America, in 1834-44, and independently, about the same time, by Thomas Hancock, in England. There are two principal kinds of vulcanised rubber, one hard

and horny in its texture, the other soft and elastic. In the case of the former the purified caoutchouc is kneaded on hot rolls with about one-half of its weight of flowers of sulphur. After pressing in tin-lined moulds, the required article is heated with steam under pressure between 250° F. and 300° F. for six to twelve hours. After cooling, it is found to be brittle and jet-black in colour, and is known as vulcanite, or ebonite. In order to obtain variations in colour and hardness, there are usually added, in addition to sulphur, substances such as resins, chalk, magnesia, sulphides of zinc, antimony, and mercury, the latter being in the form of vermilion. Pink and red vulcanites are used in the plates of artificial teeth, and are moulded by the dental operator to the required shape before vulcanisation.

For the softer vulcanised rubber the proportion of sulphur required is small, ranging from 2½ to 15 per cent., and the heat to which it is subjected in the vulcanising-chamber is considerably less than for the hard rubber goods. In both cases, as a rule, the articles are moulded before the rubber is heated. For thin sheet goods vulcanisation or 'curing' can be secured by dipping into a very dilute solution of sulphur monochloride in carbon bisulphide. Any excess which, if left in the fabric, would destroy the article is removed by washing with water. Many other substances can be used in vulcanising rubber, but their high cost, as in the case of iodine and certain iodides, prevents their use.

Another method of vulcanising rubber without heating was discovered by Mr S. J. Peachey in 1920. The rubber, solid or dissolved, is treated with sulphur dioxide and then with hydrogen sulphide. Both gases are absorbed; their interaction produces water and free sulphur in a very active form by which the rubber is vulcanised. By this method it is possible to combine vulcanised rubber with materials such as leather scraps, sawdust, paper, and various colouring matters which cannot stand heat.

Although sulphur is the only essential ingredient required for vulcanising rubber, yet other substances are usually added. Thus, in the case of machinery belting, pipes, and some other articles, silicate of magnesium (French chalk) is used to prevent adhesiveness. Litharge and carbonate of lead are frequently mixed with the rubber and sulphur for certain purposes, and so are asphalt, tar, lime, lampblack, whiting, rosin, sulphide of antimony, and ground cork. Vulcanised caoutchouc has its elasticity greatly increased, is not hardened by cold, and does not soften or become viscid at any temperature short of its absolute decomposition. It is no longer self-adhesive, and the ordinary solvents for rubber can only swell it up without dissolving it. Very often, however, the natural oil in some cloths, or oils used in manufacture, tend to make the rubber decay, and this has often caused rubber manufacturers a large amount of trouble. The action of chemicals is very similar on unvulcanised and vulcanised rubbers, but of course the nature of the loading materials in the latter is a new factor, and must be carefully studied by manufacturer and user.

Belting for machinery and some kinds of tubing are formed of alternate layers of canvas and vulcanised rubber. India-rubber when melted at 398° F., and mixed with half its weight of slaked lime, forms a useful cement or lute, which can be easily loosened, but it will dry and harden if red-lead is added. A very tenacious glue is formed by heating caoutchouc, coal-tar, and shell-lac together. It forms an ingredient in some special kinds of varnishes, and it also improves the lubricating qualities of mineral oils when a small quantity is dissolved in them.

Rubber-seed-oil compares favourably for many purposes with linseed-oil, for paints, varnishes, rubber-substitutes, oil-cloth, soft soap, &c.; and the resulting oil-cake is said to be as good for cattle-feeding as that from linseed.

Rubber, vulcanised and compounded, has been used for making roads and pavements. For india-rubber shoes, see GOLOSHES. Both coats and shoes of this material have the objectionable property of preventing the escape of moisture from the skin. Belting, buffers, wheel-tires, washers, valves, pipes, fire-hose, and other engineering appliances form a large branch of the rubber-trade. It is largely used as an insulator for electric cables. For medical and surgical purposes many articles are made of this material. Vulcanised rubber thread and tobacco-pouches are made in great quantities.

Vulcanite is made into a great many small articles, such as combs, chains, bracelets, boxes, penholders, paper-knives, knife-handles, buttons, &c., as a substitute for materials like horn, bone, ivory, and jet—being formed by moulding, cutting, carving, polishing, and other processes.

SYNTHETIC RUBBER.—Owing to the high cost of india-rubber many cheap substitutes have been invented, but none of them equal in durability the pure caoutchouc. In 1882 Professor Tilden, of London, discovered that isoprene could be made to yield a substance not unlike rubber, and from that time many attempts have been made to prepare isoprene by a commercially successful process. The following method was patented in 1907 by A. Heinemann, London: A mixture of acetylene and ethylene is heated to a dull-red heat, with the production of 'divinyl'; this body is, by the action of methyl chloride, converted into isoprene. In 1911 F. Bayer & Co., Germany, took out a patent in France for producing synthetic rubber from isoprene as follows: Isoprene is heated alone, or dissolved in glacial acetic acid or benzene, to a temperature which may vary from about 95° C. to 200° C., the time required being between ten hours and eight days, according to the conditions adopted. By some process such as this the isoprene molecules are polymerised or condensed, two molecules forming one of caoutchouc. In 1910 Dr F. E. Matthews and Professor Carl Herries independently discovered that sodium polymerises isoprene. Isoprene rubber vulcanises well, and behaves chemically like natural rubber. Owing to the cost of isoprene, synthetic rubber cannot at present compete with the natural product.

Indicator. See HONEY-GUIDE.

Indicator-diagram, a diagram drawn on an *indicator-card* by the pencil of the *indicator* of an engine at work. The object in view is to ascertain the relations between, and also the product of, the varying pressure and the corresponding variations of volume of the working substance—steam, explosive gas mixture, hot air, or other material. The variations of volume are, in a cylinder, well represented by the movements of the piston; the varying pressure may be followed by making the steam, &c., press out the piston of a small side-cylinder against the resistance of a spring. If a pencil be attached to this piston it will mark on a piece of paper or card held in contact with the point a straight line traced and retraced with varying velocity. If the steam be shut off from this side-cylinder the pencil assumes the position of 'no pressure.' If now, on the other hand, the piston of the main cylinder be made to draw the paper or card past the pencil-point in a direction at right angles to the former, the varying velocity with which a straight line is traced and retraced on the paper will reproduce the varying velocities of the main piston itself. If these two actions be now

combined the pencil will move, say, up and down, while the paper will oscillate or be unrolled backward and forward. The pencil-point will accordingly describe upon the paper an irregularly curved figure which will, in uniform working, be a closed curve, and will always tend approximately to reproduce itself during each successive cycle of the engine. Upon the scales on which the linear traces of the pencil represent, in directions at right angles to one another, the variations of pressure and the piston-movements respectively, the area enclosed by this curve will represent the work done by the engine during each cycle; and its *form* enables the actual pressures and volumes of the working substance to be traced out for each successive portion of the cycle, and thus enables the working of the engine to be carefully studied in detail. See article INTERNAL-COMBUSTION ENGINE for diagrams.

Indicatoridæ, a small family of birds. See HONEY-GUIDE.

Indiction, a period or cycle of fifteen years, the origin of which is involved in obscurity, but which was originally a fiscal term. It began to be used in reckoning time, chiefly by ecclesiastical historians, during the life of Athanasius; it was afterwards adopted by the popes, who still continue to use it, and through whose influence it came to be so generally employed during the middle ages that the dates of charters and public deeds of this era are expressed in indictions as well as in years of the Christian era. The first indiction is supposed to have commenced on September 24, 312, the day of Constantine's victory over Maxentius. If we reckon backwards to the commencement of the Christian era, it will be seen that 1 A.D. does not correspond to the 1st but to the 4th year of an indiction; hence, *if to any given year of the Christian era 3 be added, and the sum divided by 15, the remainder will give the position of that year in an indiction*—thus, 1910 A.D. is the eighth year of an indiction. Of course, such a method of marking time was necessarily incomplete, for it included no statement of the number of indictions which had elapsed since the first adoption of that method of computation.

Indictment. See CRIMINAL LAW.

Indies. See EAST INDIES AND WEST INDIES.

Indigestion, or **DYSPEPSIA**, literally means difficulty in, or failure of, digestion, and is the name given to pain or other uncomfortable sensations associated with the process of digestion. Indigestion may therefore be caused by many different diseases, but in this article only functional indigestion occurring in otherwise healthy people will be considered. The unpleasant symptoms are sometimes due to a definite mechanical cause, such as an unusual shape of the stomach, or the presence of an unhealed ulcer setting up spasms under the irritation of the food, or a scar or adhesion due to some previous disease causing difficulty to the exit of the food from the pyloric end of the stomach. Again, the difficulty may be of a secretory nature, when either too much gastric juice is secreted and the excessive acid irritates the stomach, or too little juice is formed and the food is not properly broken down into a semi-fluid chyme, but tends to remain unduly long in the stomach, undergo putrefactive changes, and dilate this organ. In another class of case the symptoms are dependent on causes outside the stomach, of which the functions are disturbed by nervous influences from disease in the appendix, the ovaries, &c., or from general debility. Still another and very important group of cases is caused by some condition of the food, such as insufficient mastication due to haste at meals or bad teeth, or excessively large meals, or improper cooking. For the purpose of recognising the type of error

and for treatment, indigestion may be conveniently classed as follows: *acid dyspepsia*, which tends to affect young persons of sedentary occupation, those who are bloodless, and persons of highly energetic nervous temperament; *chronic catarrh* of the stomach, which may come on after many years of acid dyspepsia, may be caused by undue use of alcohol, or may be associated with disorders of the circulation; *atonic dyspepsia*, occurring in persons of feeble general health, or persons exhausted by great mental or physical efforts, in whom it is liable to be associated with the moody critical state known as 'hypochondriasis'; and *fermentative dyspepsia*, in which the stomach is dilated and the food remains long in the organ and decomposes.

Acid dyspepsia appears when some time, perhaps an hour, has elapsed after a meal, with heaviness in the pit of the stomach, later a burning feeling (heartburn) about the centre of the chest, and sometimes the pouring out of great quantities of saliva (water-brash). The pain may come and go in a spasmodic manner, and if vomiting occurs the vomit is intensely sour and may contain streaks of blood. In treating this condition, regularity of meal-times, sufficient exercise in the open air, proper chewing of the food, the avoidance of constipation, and the taking of small meals are important. All condiments such as vinegar, mustard, pickles, and particularly salt, as also meat and strong stock-soups, should be avoided. The food should be simple and unstimulating, such as eggs, fish, thick soups, milk-puddings, and the like. When pain is severe, it may be eased by taking powders of rhubarb, soda, and bismuth after meals, or by small doses of Dover's powder. *Chronic catarrh* is associated with a furred tongue, and with a poor, capricious appetite; there are discomfort, eructations, and choking sensations after a meal, and very often vomiting, especially in the morning, when much mucus is brought up. Alcohol should be stopped; pickles, salted food, and other stimulating articles of diet are allowable; the appetite may be increased by taking bitters like calumba, condurango, and nux vomica half-an-hour before meals. A glass of warm water taken in the early morning with a saline aperient if necessary is often very beneficial. *Atonic dyspepsia* requires the administration of tonics of various kinds; persons whose work is very engrossing should rest for half-an-hour before and after each meal. When the secretion of gastric juice is poor it is a good plan to commence a meal with well-seasoned clear soups of meat extract; otherwise the food should be highly nutritious and of small bulk. *Fermentative dyspepsia*, in which a constant sense of weight is felt in the pit of the stomach, relieved at times by vomiting large quantities of fermenting, frothy, and partially digested food, requires the avoidance of fats and starchy food; the meals should be as dry as possible, and the fluid limited. Washing out of the stomach is often very beneficial in this form. The chemical examination of the gastric juice and the X-ray examination of the patient after a 'bismuth meal' have both added much to the precision of diagnosis in this and other forms of dyspepsia.

Indigirka, a river in the Siberian government of Yakutsk, rises in a western offshoot of the Stanovoi Mountains, and, after a northerly course of 870 miles through a desolate and frozen desert, falls into the Arctic Ocean in 71° N. lat. and 150° E. long.

Indigo (Lat. *Indicum*, the Indian substance or pigment), a dyestuff which was used in India and Egypt before the Christian era, and is still regarded as one of the most important of all colouring matters. It was introduced into Europe in the 16th century, but for a long time Western culti-

vators of the woad-plant (*Isatis tinctoria*—its European rival) were instrumental in prohibiting its general use. The woad, though still grown in some parts of Europe, is now only employed along with indigo in the 'woad-vat' process in wool-dyeing. Natural indigo is prepared from various plants, the genus *Indigofera* being its chief source; but to some extent it is also obtained from *Wrightia tinctoria* (India), *Polygonum tinctorium* (China), *Lonchocarpus cyaneus* (Africa), &c.

The bulk of natural indigo comes from India, smaller quantities also being imported from Java, Guatemala, Egypt, &c.

Indigo does not exist as such in the plant, but is contained principally in the leaves as a colourless compound called *indican* ($C_{12}H_{17}O_6N \cdot 3H_2O$), a glucoside of *indoxyl*, $C_8H_7\langle\begin{smallmatrix} C(OH) \\ NH \end{smallmatrix}\rangle CH$. The conversion of indican to (natural) indigo is effected by 'steeping' and 'beating' (operations employed in the manufacture of the dyestuff), and is mainly due to the united action of a specific enzyme called *indimulsin* or *satase* (which hydrolyses the indican to glucose and indoxyl—bacteria also apparently playing a minor part in this 'fermentation'), and of atmospheric oxygen (which oxidises the resulting indoxyl to *indigotin*). To indigotin, which is the blue colouring matter of indigo, and its most important constituent, the following formula is assigned: $C_8H_7\langle\begin{smallmatrix} CO \\ NH \end{smallmatrix}\rangle C:C\langle\begin{smallmatrix} CO \\ NH \end{smallmatrix}\rangle C_8H_7$. In addition to this compound natural indigo contains varying proportions of *indigo red* (indirubin), *indigo brown*, *indigo yellow* or *kämpferol* (from *I. arrecta*), *indigo gluten*, mineral matter, and moisture.

Bengal indigo (which is now mainly employed in England) is made from *Indigofera sumatrana*. The latter, however, is now being replaced by *Indigofera arrecta* (the Natal plant), from which better results are obtained. An outline of the manufacture from *I. sumatrana* is given here. The seed of the plant is sown about the end of February or the beginning of March, and by the middle of June the first crop is gathered, a second crop being secured about three months later. The plants, after being cut down, are tied in bundles and directly conveyed to the indigo-factory. Here, under suitable conditions of time and temperature, an *aqueous extract* of the plant is prepared in 'steeping-vats.' The orange-to-green liquor thus obtained is then run off into lower 'beating-vats,' where it is freely brought into contact with atmospheric oxygen by 'beating'—a process now generally accomplished by various artificial methods—e.g. by means of steam blowers or air compressors. The resulting indigo is then allowed to settle. It is next collected as a mud (called 'mal'), and prepared for the market after being sterilised by boiling, pressed, cut into cubes, and dried.

The average amount of indigo from 100 lb. of fresh plant is stated to be about 4 oz. Superior qualities of natural indigos have a deep violet-blue colour, and, among other properties, show a bronzy lustre when rubbed with the finger-nail. Good Bengal indigo contains on an average from 60 to 66 per cent. of indigotin.

The synthetical production of indigotin (identical with natural indigotin) has also been effected. This was first accomplished in the laboratory in 1878, when Baeyer synthesised *isatin* ($C_8H_5NO_2$); for in 1870 Baeyer and Emmerling converted *isatin* into *indigotin*. The first patent for the production of so-called 'artificial' or 'synthetic indigo' was taken out by Baeyer in 1880, who prepared it from *ortho-nitrocinnamic acid*, $C_8H_7(NO_2)CH:CH \cdot COOH$; and in 1882 Baeyer and Drewsen obtained it from *ortho-nitrobenzaldehyde*, $C_6H_4(NO_2)CHO$. Neither of these methods, however, proved a commercial

success. Since then synthetic indigo has become a very serious rival to the natural varieties; but for its successful preparation either of the cheaper coal-tar products *benzene* or *naphthalene* has served as a starting-point. Some account of these processes is now given. In 1890 Heumann discovered a synthesis from *phenylglycine* ($C_6H_5NHCH_2COOH$), which was subsequently so developed that in 1897 'artificial indigo' was placed on the market as 'indigo pure' by the Badische Anilin und Soda-Fabrik. *Naphthalene* ($C_{10}H_8$) is the raw material for this synthesis (Heumann's). By means of fuming sulphuric acid (in the presence of mercuric sulphate acting as a catalyst), *naphthalene* is finally changed to *phthalic anhydride*. The latter compound is converted by ammonia into *phthalimide*, and this on treatment with an alkaline hypochlorite yields *anthranilic acid*. On condensing the last-named compound with monochloroacetic acid, *phenylglycine-ortho-carboxylic acid* is obtained. The latter compound on fusion with caustic alkali (potash) is changed first into *indoxyl acid* and then into *indoxyl*. The fused mass thus obtained, on treatment with water and exposure to atmospheric oxygen, yields *indigotin*. These successive changes may be represented by the following scheme:

Heumann's synthesis, with its various modifications covered by numerous patents, has proved one of the most successful methods for the production of 'artificial indigo.' Of other processes now in use for the same purpose, which, however, start from *benzene* (C_6H_6), mention may be made of Rahtjen's improved method of Sandmeyer through *diphenylthiourea*, $SC(NHC_6H_5)_2$, and more particularly that successfully employed by the Höchst Farbwerke, which depends upon the action of *sodamide* on the sodium salt of *phenylglycine*. The various steps in the latter process may be thus indicated:

The introduction of artificial indigo into the market in 1897 soon affected the price and output of the natural dyestuff. Thus by 1905 artificial indigo was sold at one-half the price of the natural dye, and in 1907 the total production of artificial indigo was four-fifths of the world's consumption. To-day the synthetic dyestuff has very considerably supplanted the natural varieties. That the latter still retain even a portion of the world's markets is no doubt due to the investigations of Rawson, Perkin, Bloxam, Bergtheil, and other experts, which have led to the adoption of scientific methods for improving the agricultural and manu-

facturing side of the industry in India and elsewhere.

Indigotin is a blue compound showing a bronzy lustre when rubbed. It is not soluble in water, but dissolves in glacial acetic acid, nitrobenzene, &c. Heated in vacuo it forms a coloured crystalline sublimate from which pure indigotin may be obtained. Reducing agents change indigotin to *indigo white* ($C_{16}H_{12}N_2O_2$), which in alkaline solution and exposure to air is oxidised back to *indigotin* ($C_{16}H_{10}N_2O_2$). These reactions are important, for on them the use of indigo as a dyeing and printing agent is based. Oxidising agents change indigotin into isatin, and with sulphuric acid (concentrated and fuming) various indigotin sulphonic acids result. Of these the *tetra-sulphonic acid* may be used in purifying commercial indigo for analysis, and the sodium salt of indigotin disulphonic acid, $C_{16}H_8N_2O_4(SO_3H)_2$, also known as sulphindigotic acid, constitutes commercial *indigo carmine*.

Of late the attention of chemists, dyers, and calico-printers has been directed to *synthetic* 'vat-dyes,' which can be used in dyeing like indigo. Some of these compounds exceed indigo in brightness and fastness, and, while several of them—the so-called '*indigoids*'—are similar in constitution to indigotin, a large number are really derivatives of *anthraquinone*. The *halogen* derivatives of indigotin can be regarded as representatives of one class of 'indigoids,' while derivatives of it containing *sulphur* typify another class. To the latter belong the technically important *thioindigotins*, e.g. *thio-indigo red* B, $C_8H_4 \begin{smallmatrix} \diagup CO \\ \diagdown S \end{smallmatrix} C=C \begin{smallmatrix} \diagup CO \\ \diagdown S \end{smallmatrix} C_8H_4$; *thio-*

indigo scarlet R, $C_8H_4 \begin{smallmatrix} \diagup CO \\ \diagdown S \end{smallmatrix} C=C \begin{smallmatrix} \diagup CO \\ \diagdown S \end{smallmatrix} C_8H_4 NH$, &c.; and to the former the *bromindigotins*, e.g. *Ciba blue* 2B (5:7:5':7' tetra-bromindigotin), *indigo* 2R (5 bromindigotin), &c. One of the bromindigotins, viz. 6:6' dibromindigotin,

although not a commercial article, is nevertheless of interest, for it has been proved to be identical with the Tyrian purple of the ancients, which, however, was of animal origin. Artificial indigo and the various indigoids are met with commercially as powders and pastes, the former compound as a powder of 98 per cent. purity, and as a paste containing about 20 per cent. indigotin.

Indigo Bird (*Cyanospiza cyanea*), a bird of the Finch family (Fringillidae), found in the United States in summer, and Central America in winter. It is about 5½ inches in length, of a beautiful blue colour, variously tinged and shaded. It frequents open places on the edges of woods, and has a very sweet song.

Indigofera, a tropical genus of Leguminosae, yielding Indigo (q.v.).

Indium, a metal (In; trivalent; atom. wt. = 114.8; atom. numb. 49), soft, silver-white, malleable, soluble in HCl. Its sulphate forms alums with alkaline sulphates. It was discovered in 1863 by Reich and Richter in Freiberg zinc-blende, through observing in its spectrum two characteristic indigo-blue lines.

Individualism. See SOCIALISM.

Indo-China, the eastern of the two great Asiatic peninsulas which extend southwards into the Indian Ocean, sometimes called Further India. It is washed on the east by the Gulfs of Tongking and Siam and the Chinese Sea, and on the west by the Bay of Bengal. Accounts of the various countries which it embraces will be found under

the headings ANNAM, BURMA, CAMBODIA, COCHIN-CHINA, MALACCA, SIAM, and TONGKING.—The term *Indonesia* is sometimes used for the Indian Archipelago, the islands to the south-east of Asia.

Indo-European, Indo-Germanic. See ARYANS, PHILOLOGY.

Indore, a Mahratta principality of India, comprising the territories of the Holkar dynasty, and consisting of several detached tracts, covers an area of about 9500 sq. m. The bulk of it lies between Sindhia's dominions on the north and Bombay Presidency on the south, its length from north to south being 120 miles, and its breadth 82. It is traversed from east to west by the Nerbudda, which almost bisects it; by the Vindhya Mountains, their loftiest point within its limits being 2500 feet above the sea; and by the Satpura Mountains. Principal products, cotton, tobacco, wheat, rice, millet, silk, &c.; principal industry, cotton manufacture. Pop. over 1,000,000. The Vindhya and Satpuras have from time immemorial been the home of the Bhils (q.v.), the wildest of the aboriginal tribes in India. The Holkar State Railway (Indore to Khandwa) is a section of a branch of the Rajputana-Malwa railway traversing the state. The climate is sultry, the thermometer ranging from 60° to 90° F. in the shade. The state was founded about the middle of the 18th century by Malhar Rao, a soldier of fortune, who served the Peshwa. In 1818 the ruler of the Holkar dominions was reduced to the position of a feudatory prince of the British Indian empire.

Indore, the capital of the Maharaja Holkar's dominions, is situated in 22° 42' N. lat. and 75° 54' E. long., 1786 feet above sea-level. Population 93,000, mostly Hindus. During the revolt of 1857, though the maharaja remained faithful to the British government, his troops mutinied on 1st July, holding their prince a prisoner in his own palace, and butchering many Europeans in cold blood. The town dates only from 1770. Close to the town is the district specially set apart for the residence of the Governor-general of India's agent for Central India. Within this district stand a celebrated European hospital and a college for sons of Central Indian chiefs.

Indorsement, the term generally used to denote the writing of the name of the holder on the back of a bill of exchange or promissory note, on transferring or assigning it to another. Signing the name 'A. B.' alone is a blank indorsement; and if the transferee is named it is an indorsement 'in special' or 'in full.' The usual form is 'Pay C. D. or order. (Signed) A. B.' Indorsement may also be restrictive—that is, may prohibit further negotiation. When personal liability is to be avoided the words 'without recourse' are added, and in this case no demand can come back on the indorser, who would otherwise be liable. The word indorsement is also frequently used in English law to denote any matters written or indorsed on the back of writs or deeds, as indorsements on declarations, on writs of summons, &c.

Indra, the name of one of those Hindu deities that were worshipped more especially in the Vedic period of the Hindu religion, but enjoyed a great legendary popularity also in the Epic and Puranic periods. In those R'ig-Veda hymns which form the oldest portion of Vedic poetry Indra is a mighty ruler of the bright firmament, and his principal feat is that of conquering the demon *Vritra*, a symbolical personification of the cloud which obstructs the clearness of the sky and withholds the fructifying rain from the earth. All his wonderful deeds are performed by him merely for the benefit of the good, which, in the language of the Veda, means the pious men who worship him in their songs, and invigorate him with the offerings

of the juice of the Soma (q.v.) plant. He is therefore the 'lord of the virtuous,' and the 'discomfiter of those who neglect religious rites,' and at the same time he has all the attributes of a war-like god, and is invoked as the destroyer of cities. During the Epic and Puranic periods, where ethical conceptions of the divine powers prevail over ideas based on elementary impressions, Indra ceases to enjoy the worship he had acquired at the Vedic time, and his existence is chiefly upheld by the poets, who, in their turn, however, work it out in the most fantastic detail. A remarkable trait in this legendary life of Indra is the series of his conflicts with Krishna, an incarnation of Vishnu, which end, however, in his becoming reconciled with the more important god. When represented in works of art Indra is generally seen riding on his elephant; and where he is painted he is covered with eyes.

Indre, a department of France, formed principally out of the western portion of the old province of Berri, lies immediately south of the department of Loir-et-Cher; area, 2664 sq. m., of which about four-fifths are in tillage and pasture; pop. (1872) 277,693; (1886) 296,147; (1921) 260,535. It is quite flat, and well watered by the Indre (which flows from the department of Creuse, 152 miles north-westward to the Loire) and the Creuse. It contains three well-marked districts—a stony, woody region with sandy soil in the south, a fertile agricultural region in the east, and in the north-west a region of moors, marshes, and ponds, interspersed with forests. The more notable products are wheat, oats, potatoes, turnips, fruits, and wine. The sheep are excellent as food, and produce first-rate wool. Much poultry is reared. The principal manufactures are of iron, cloth, paper, leather, and porcelain. The department is divided into four arrondissements—Châteauroux, Le Blanc, Issoudun, and La Châtre. The capital is Châteauroux.

Indre-et-Loire, a department of France, formed chiefly out of the ancient province of Touraine, is crossed by the Loire from N.E. to S.W.; area, 2337 sq. m.; pop. (1872) 317,027; (1911) 341,205; (1921) 327,743. It is watered by the Loire and its tributaries, the Cher, Indre, and Vienne, all of them navigable. The valley of the Loire is very fertile, studded with orchards and gardens and vineyards; it is called the 'garden of France.' South of this lies the monotonous but productive plateau of St. Maure, north of it the sterile region of Gâtine. The products include grain, wine, fruits (especially plums), and hemp. The industry has never recovered from the blow struck by the Edict of Nantes. The chief manufactures are powder, flax, cloth, paper, and leather. The department is divided into the three arrondissements of Tours, Chinon, and Loches; capital, Tours.

Induction, one of the great processes of scientific discovery and proof. It is the operation of *discovering* and *proving* general propositions; while deduction, on the other hand, is the method of *applying* general propositions once discovered to particular cases considered to be included within their scope. By induction we establish the law that heat expands bodies; by deduction we apply it to explain why a clock goes slower in summer than in winter; owing to the changes of the length of the pendulum. It should be mentioned that what has been called *perfect induction*—the observation of *all* the instances and a statement of the result in one general proposition—is not by Mill or the moderns recognised as proper induction at all. Induction is the process of real inference—in other words, by it we proceed from the known to the unknown; or from a limited range of facts we affirm what will hold in an unlimited range.

All things that we do not know by actual trial or ocular demonstration we know by an inductive operation. Deduction is not real inference in this sense, since the general proposition already covers the case that we apply it to; in a proper deduction the conclusion is more limited than the premises. By the inductive method we obtain a conclusion much larger than the premises; we adventure into the sphere of the unknown, and pronounce upon what we have not yet seen. Nothing is more common than the making of bad inductions, and accordingly it is now considered a part of logic to lay down the rules for the right performance of this great operation.

See Mill's *Logic* (book iii.); more recent works on logic by Fowler, Venn, Bradley, Bosanquet, Welton, Boyce Gibson (1908); Hobhouse's *Theory of Knowledge* (1896); also the article LOGIC.

Induction is a term used in England to denote the investing or giving possession of a benefice to a clergyman. This is done by a mandate from the bishop to the archdeacon (in some places the dean and chapter) to make the induction. The inductor takes the clergyman by the hand, and lays it on the key of the church-door (or some part of the church itself), then opens the door and causes him to enter the church alone, and to toll one of the bells as a public notification to the parishioners. The incumbent's possession of the benefice is completed by 'reading himself in'—i.e. reading, generally on the following Sunday, the Thirty-nine Articles, and immediately thereafter making a formal declaration of assent to their doctrine, and giving a pledge of his conformity to the rules of the church.—In Scotland the presbytery induct the minister.

Induction, in Electricity and Magnetism, is a term of various application. In every case, however, there is a certain idea present—the idea, namely, of an effect produced at an apparent distance from the producing cause, the effect being essentially a reproduction of the cause. More accurately stated, induction is the name of a method or mode by or in which a particular electric or magnetic condition is made to pass from one material system to another without the intervention of any obvious material connection. Thus, in static electricity a metallic body or other conductor brought into the neighbourhood of an electrified body becomes itself electrified by induction. Similarly, a piece of iron or other magnetisable metal, when brought near a magnet, or, more generally, when brought into a magnetic field, becomes itself magnetised by induction. Indeed, according to Faraday's view, induction is the essential feature in all electric and magnetic interaction. These two fundamental cases of induction will be found treated in full under ELECTRICITY and MAGNETISM.

There is, however, a third and very important group of electric and magnetic phenomena to which the name induction belongs. These were discovered by Faraday, and will be treated in a general way under MAGNETISM. The essential peculiarity of this class of induction phenomena is the production of electric currents in conductors or circuits in which there exists no source of electrical energy. These induced electric currents are in all cases the result of some magnetic change in the region occupied by the conductor. This magnetic change may be produced by the approach or withdrawal of a magnet; or it may be produced by the motion of the conductor in a constant magnetic field; or it may be due to variations of primary currents in neighbouring conductors, or even in the conductor itself. In this last case the variations of these primary currents cause

corresponding variations in the magnetic fields existing with them, so that the induced current can always be explained in terms of a magnetic change. According to Ohm's Law (see ELECTRICITY), the strength of a current flowing through a given circuit depends on the electromotive force which excites the current, and on the resistance of the circuit through which the current is made to flow. In the case of induction of currents the electromotive force is directly due to, and is measured in terms of, the rate of change of the number of lines of magnetic force embraced by the circuit; and this rate of change depends on the geometrical form of the circuit and on its space relations to the magnetic field surrounding it. Thus the induced current depends on three things—viz. the form of the circuit, the varying space relations of the circuit and the magnetic field, and the ordinary ohmic resistance of the circuit.

One of the readiest ways of producing induced currents is to have two coils of wire, one placed inside the other, and to pass through the inner or *primary* coil a current of varying strength. At every variation of the primary current a current is induced in the outer or *secondary* circuit. The direction of the secondary current depends on the manner of change of the primary. If the primary current is decreasing in strength, the induced current in the secondary circuit flows in the same direction as the primary in its circuit; but if the primary current is increasing, the secondary current flows in the reverse direction. The best effects are produced at the 'making' and the 'breaking' of the primary circuit; for by these operations the primary current is made to have its greatest variations. This is the principle of action of the *Ruhmkorff Induction Coil*, one of the many forms of which is shown in the figure. The coils are wound, the primary inside the secondary, on the

portion marked W. The battery wires, attached to the binding screws, *p*, *n*, are brought into connection with the terminals of the primary coil by means of the commutator, C. The terminals of the secondary coil are fixed to the brass heads of the glass pillars, P, P', which are furnished with pointed rods capable of universal motion. The true way of looking at the action of this instrument is to regard the primary current as the source of a magnetic field within and around the coils. To intensify the magnetic field it is usual to introduce a soft iron core into the centre of the coils. In virtue of magnetic induction this iron core, under the influence of the magnetic force due to the primary current, becomes powerfully magnetised, and the magnetic field within the coil greatly increased. When the primary current is interrupted the iron core loses nearly all its magnetism, and accompanying this great decrease in the strength of the magnetic field an intense induced current flows in the secondary circuit. Now it is only when the magnetic field is varying that the induced electromotive force exists; and, since in a given secondary circuit the total current induced is proportional to the total change in the

magnetic field, it follows that the more abrupt this change the more concentrated will be the flow of the secondary current.

In the induction coil matters are so arranged that the induced current is sufficiently concentrated to pass across a considerable air-space, which really forms part of the secondary circuit. By taking the terminals of the secondary circuit in our hands we may make ourselves part of this circuit, and experience the curious throbbing sensation of a galvanic shock. Or we may attach the terminals to the platinum wires of a Geissler tube, and produce the beautiful effects of electric discharge through gases in a state of great rarity. In most forms of induction coil the primary current is broken and made automatically, the varying magnetic strength of the iron core being used for this purpose. When the primary current passes, the iron core becomes a powerful magnet, and attracts a small iron disc set opposite one end. By means of a simple form of lever attachment this disc when so moved interrupts the primary circuit. The current then ceases to flow, the iron core loses most of its magnetism, and the small iron disc thus freed returns to its original position. With this return of the disc the primary circuit is again completed, the current flows as before, and the same order of effects is repeated, and so on indefinitely. In the secondary coil there is, of course, a possible induced current at make as well as at break. But, as in such instruments the corresponding magnetic change is not nearly so rapid at make as at break, the induced current is not so concentrated. Hence, practically, in working with an induction coil we have to do only with the induced current due to the interruption of the primary circuit.

The Telephone (q.v.) is an instrument whose action depends largely upon the laws of electromagnetic induction; and in the same category we may include the induction balance of Professor Hughes, which illustrates in a marvellous way the sensitiveness of a variable current flowing in a circuit to the presence of a small piece of metal or other conducting material.

Indulgence, in Roman Catholic theology, means a remission, by church authority, to a repentant sinner of the *temporal* punishment which, in the Catholic theory, remains due after the sin and its eternal punishment have been remitted. By the discipline of the first centuries a severe course of penitential observance was exacted of all who fell into any grievous crime, especially apostasy, murder, and adultery, such sinners being excluded from church communion for various periods, in some cases even till the hour of death. These penitential observances, which Protestants regard as purely disciplinary, were designed, according to the Catholic view, as an expiation on the part of the penitent for the *temporal* punishment which, after sin and the *eternal* punishment due to it have been remitted by God, still remains to be undergone: and some of the most acrimonious of the early controversies, the Montanist and the Novatian, arose as to the power of the church to relax these penitential observances, and to admit grievous sinners to communion. These ancient relaxations (of which they regard that referred to in 1 Cor. v. 5 and in 2 Cor. ii. 10 as a type) are considered by Catholics as examples of the modern indulgence; and the practice which grew up in the 3d and 4th centuries, and which even then was carried to great extremes, of granting such relaxations on the recommendation of martyrs or confessors, is held by Catholic theologians to be an illustration of that principle of vicarious atonement according to which, in the theory of indulgences, the church

is supposed to supply from the inexhaustible treasure of the merits of Christ, and of the 'supererogatory' works of the saints, what may be wanting to the completeness of the atonement of the less perfect but yet truly penitent sinner to whom she grants the indulgence. That this practice of relaxation, whatever may have been its real import, was to be used according to the judgment of the bishop as to the disposition of the penitent, is expressly laid down by the Council of Ancyra in 308 and by that of Nice in 325. In all cases, however, the person granting the relaxation was to impose certain good works as a partial substitute for the penalty which had been relaxed; and among these works, which had at first been purely personal, came by degrees to be included money payments for certain religious or charitable objects, as the building of a church or the foundation of a monastery or hospital.

The name indulgence appears to have originated late, the first recorded instance of its use being by Alexander II. in the 11th century; but the institution itself is found in full development during the wars of the Crusades, the serving, or the contributing to service in which, 'provided it were for devotion alone, and not from motives of greed or of glory,' was accepted in the Council of Clermont 'as an equivalent substitute for all penance.' Such an indulgence was called 'plenary'; where a portion only of the penitential works was relaxed it was called 'partial'; and in order to put a bar to their excessive multiplication and to other abuses Innocent III. declared the power of granting 'plenary indulgences' to be reserved to the pope alone, bishops being only authorised to grant the 'partial' or limited indulgences described above. The fourth Lateran council condemns the 'indiscreet and superfluous' granting of indulgences; and among the abuses which grew up in the church during the western schism one of the most remarkable was the lavish dispensation of indulgences, in the granting of which the contending popes rivalled each other in prodigality. The last extreme, however, was not reached until the beginning of the 16th century, when, with a view to raising the funds necessary for the erection of the great church of St Peter's at Rome, the pope, Leo X., published a plenary indulgence, the principal condition for the gaining of which was a contribution to this work. Catholic historians contend that in itself such a condition was perfectly justifiable, and that if duly explained to the people it might be lawfully and even meritoriously complied with; but they admit that Tetzel and many more preachers of the indulgence in extolling its natural effects went to indefensible extremes, and that, even making the fullest allowance for exaggeration, it cannot be denied that grievous abuses both of doctrine and of practice were committed in Germany and in Switzerland. Hence the decree of the Council of Trent, while it affirms that the use of indulgences, as being 'most salutary for the Christian people, and approved by the authority of councils, is to be retained in the church,' yet orders that 'in granting them moderation be observed, lest by excessive facility discipline may be enervated.' Upon the special instructions of this council all the modern legislation on the subject of indulgences has been founded; but as the decree of the council does not explicitly declare what is the precise effect of an indulgence it is further explained by Pope Pius VI., in his celebrated bull *Auctorem Fidei*, that an indulgence received with due dispositions remits not alone the canonical penance attached to certain crimes in this life, but also the temporal punishment which would await the penitent after death to be endured by him in purgatory.

From the above explanation it will be gathered that Catholics do not understand by an indulgence a remission of sin, much less a permission to commit sin or a promise of forgiveness of future sin. They contend, moreover, that, since the benefit of an indulgence can only be enjoyed by a sinner who has repented of sin and resolved to embrace a new life, the imputation of introducing laxity of principle and easy self-indulgence is entirely unwarranted. And although for the most part the good works which are required as the condition of obtaining indulgences may appear easy and even trivial, yet the one indispensable preliminary—sorrow for sin and sincere purpose of amendment—involves the highest effort of Christian virtue.

See vol. iii., H. C. Lea's *History of Auricular Confession and Indulgence* (1896).

THE DECLARATION OF INDULGENCE, proclaimed by James II. in 1687, promised to suspend all laws which tended to force the consciences of his subjects. His real aim was, of course, merely to relieve the Roman Catholics; hence the declaration was very unpopular, and the refusal of the Seven Bishops to command their clergy to read it from their pulpits was but the culminating point of universal public dissatisfaction. Two similar indulgences in English history were those issued by Charles II. in 1662 and 1672, both of which were equally unpleasant to the dissenters alike in England and Scotland, who declined to share their toleration with their Roman Catholic fellow-subjects.

Indus (Sansk. *Sindhu*), a river of India, whose source was discovered by Hedin in 1907, rises in a sacred spring, the Singikabab, on the N. side of the Trans-Himalayan range, NNE. of Kailas, 16,946 feet above the level of the sea. Its general course is at first towards the north-west, through Tibet and Kashmir. In the north-west of Kashmir, in about 34° 50' N. lat. and 74° 30' E. long., it turns abruptly southwards, and follows that direction, varied by stretches to the south-south-west, right down to the sea. In the mountains its current is very rapid; the river passes through deep, wild gorges (one near Iskardoh, in north-west Kashmir, having a sheer depth of considerably more than 10,000 feet), and is liable to floods, which come with terrible swiftness, rise very high, and cause tremendous damage. The Indus enters the Punjab about 800 miles from its source. Near Attock (q.v.), 48 miles lower down, it receives the Kabul River from Afghanistan, and then becomes navigable. Here it is only 2000 feet above sea-level. 450 miles below Attock it receives, on the left, the accumulated waters of the Punjab through the single channel of the Panjnad. Each of the 'five water-courses,' as well as the Kabul, is practicable for inland craft to the mountains. Below its confluence with the Panjnad the Indus, instead of increasing in volume, becomes gradually less. Its basin is narrow, and the affluents are insignificant, while there is a great loss by evaporation. The river also divides into numerous channels, many of which become lost in the sand, while others return much shrunken in volume. The delta of the river covers an area of about 3000 sq. m., and extends for some 125 miles along the Arabian Sea. The main channel is constantly shifting. The delta is not on the whole very fertile, and is almost entirely destitute of trees. In both Punjab and Sindh the bed of the river is littered with islands and sandbanks. The cultivation of the arid plains through which the lower Indus passes is dependent upon the annual overflow of the river and artificial irrigation fed by that overflow. The Sukkur barrage dwarfs all earlier undertakings of the kind. The total length of the river is estimated at somewhat more than 1800 miles, and the area of its drainage

basin at 372,700 sq. m. The Indus abounds with fish of excellent quality, and is infested by crocodiles. Before the opening of the Indus Valley Railway in 1878 the river was necessarily the principal means for the transmission of commerce, but since that event the railway has very greatly superseded navigation.

Industrial Schools. See EDUCATION, TECHNICAL EDUCATION, RAGGED SCHOOLS, REFORMATORY AND INDUSTRIAL SCHOOLS.

Inebriates, RETREATS FOR. The Habitual Drunkards Act, 1879, amended and made permanent by the Inebriates Act, 1888, made provision for the licensing of institutions for the reception and treatment of habitual drunkards. By these acts an inebriate might sign a bond before two justices of the peace for a period not exceeding twelve months, under which the licensee of the retreat had power to detain and control him during the time specified. No provision was made for the committal of any one against his will, nor for the establishment of retreats for the reception of persons unable to pay for their maintenance. The Inebriates Act of 1898 gives power to courts of justice to commit persons convicted of penal offences whose offence may be traced to drink, or who may be found to be habitual drunkards, to three years' detention in a state (or certified) inebriate reformatory. See also the Children Act, 1908, sect. 26. The Secretary of State is empowered to establish state inebriate reformatories, or, on application from county or borough councils or private persons, to certify private inebriate reformatories. Full provision is made for the conducting and management of these institutions. The act applies to the whole United Kingdom. An amending act (1899) provides for the payment of expenses of prosecutions under the act.

Inertia (Lat., 'inactivity'), a universal property of matter, fully described in Newton's first law of motion, which asserts that *every body perseveres in its state of rest or of uniform motion in a straight line except in so far as it is compelled by force to alter that state*. Part of this principle was known to the ancients, and by them attributed to a certain repugnance to motion, which was a characteristic of all matter; but it was shown by Galileo that just as the body at rest could not of itself begin to move, so the body in motion could not of itself come to rest. The same principle applies to rotation round an axis, in which torque (=moment of force) takes the place of 'force' in Newton's first law; whence the Gyrostat (see GYROSCOPE). Dynamically the inertia of a body (in translatory movement) may be identified with its mass; and it has been found that the apparent mass of electrons, travelling with velocities approaching that of light, increases very rapidly with the velocity, so that it has been computed that the smallest material particle, travelling with the velocity of light, would present an infinite inertia, and could not be made to move any faster. Further, as this increase of inertia with increasing velocity depends on the charge borne by the electron, and as this charge alone is competent to explain all the inertia, it has been inferred that there is no residuary 'mass' other than the electric charge on the electron, and that the inertia of ordinary 'matter' may be wholly due to the extreme velocity of the charges, or electrons, in their orbits within the atoms. It is computed that an increment E in the energy of a body corresponds to and implies an increment of E/c^2 in its inertia or mass, where c is the velocity of light. A ray of light, therefore, acting as a carrier of energy E , must have a mass E/c^2 and be attracted by the Sun.—The *Moment of Inertia* is the sum of the products of every particle of a mass into the square of the corresponding distance from

a given point or axis of rotation; and this corresponds, in rotational mechanics, to mass in translational mechanics.

Infallibility, the immunity from error, in all that regards faith and morals, which is claimed by the Roman Catholic Church, and, at least as regards the past, by the Greek Church, as represented in the decrees of the councils which that church looks upon as ecumenical. The latter claim, however, which does not go beyond that of *inerrancy*, or actual exemption from error up to the present time, differs widely from that of infallibility, as put forward by the Roman Church, which involves not alone an actual historical immunity from error, but also such a positive and abiding assistance of the Spirit of God as will at all times both protect against the possibility of error and guide and direct in the faithful teaching of all necessary truth. The infallibility claimed by the Roman Church is thus of two kinds, *passive* and *active*—the first (Matt. xvi. 18), in virtue of which the church never can receive or embrace any erroneous doctrine, no matter by whom proposed; the second, in virtue of which she is charged with the function (Matt. xxviii. 19; Mark, xvi. 15; Ephes. iv. 11-16) of permanently teaching to the world the essential truths of God, of actively resisting every access of error, and of authoritatively deciding every controversy by which the oneness of belief among the faithful may be endangered. Catholics regard this gift as a natural and necessary accompaniment of the authority in matters of faith with which they believe the church to be invested, and which, if not guided in its exercise by such infallible assistance, would be but a false light and an attractive but dangerous instrument of delusion.

Such is the notion of infallibility as claimed by the Roman Church. Two very important and practical questions, however, arise regarding it, both of which have been the occasion of much controversy even among Catholics themselves: (1) as to the *subject*—the seat or the organ of this infallibility, and (2) as to the *object*—the matters to which it extends.

As to the first, all Catholics have been agreed that the body of bishops, morally speaking, throughout the church, acting in common with the pope, constitute the most perfect organ of the infallibility of the church; and hence, that when they unite in any way, whether assembled in a general council or separated in place, their judgment is infallible. Thus, if a doctrinal decree was addressed officially by the pope to the whole church, and either expressly confirmed or tacitly accepted by the bishops, this decree was held to be infallible. In like manner, if a doctrinal decree, emanating even from a local council, as that of a national, or even a provincial church, was universally accepted by the pope and the bishops, that decree also was held to be infallible. In a word, wherever there is found the *united* judgment of the pope and the bishops, all have agreed in accepting it as the infallible judgment of the church. But should the pope alone judge without the bishops, then arose the well-known dispute of the Gallican and Ultramontane divines; the latter affirming, the former denying, the papal judgment to be infallible; but all agreeing that it was not binding as an *article of Catholic faith* so long as it had not received the assent of the body of the bishops. By the decree of the Vatican Council (1870) this controversy was decided after much discussion; the constitution *Pastor Aeternus* teaches 'that when the Roman Pontiff speaks *ex cathedra*—that is, when he, using his office as pastor and doctor of all Christians, in virtue of his

apostolic office defines a doctrine of faith and morals to be held by the whole church—he by the divine assistance, promised to him in the blessed Peter, possesses that infallibility with which the Divine Redeemer was pleased to invest his church in the definition of doctrine on faith or morals, and that therefore such definitions of the Roman Pontiff are irreformable in their own nature and not because of the consent of the church.’ See POPE, ROMAN CATHOLIC CHURCH.

On the matters or subjects to which the gift of infallibility extends Catholics are agreed in one principle, that it embraces all those subjects, and those only, which are necessary for the maintenance of divine truth in the church. Hence, presupposing divine revelation, either written or oral, it embraces all questions of faith and morality, all subjects of general discipline, so far at least as to preclude the introduction, by authority of the church, of any discipline which should be injurious to faith or to morality. On the other hand, it does not embrace questions of science, or matters of fact, or abstract opinions unconnected with religion. On this point all Catholics have been agreed. But on occasion of the *Augustinus* of Jansen (q.v.) arose the former dispute as to the infallibility of the church in judging of books, and the Jansenist distinction of law and of fact. All Catholics now recognise as a necessary condition to effective infallibility that it should extend to the judgments upon books so far as to decide whether the doctrine contained is opposed to sound faith or morality.

[The Vatican Council produced a large literature, including Cecconi, *Storia del Concilio Vaticano* (1873-74); see VATICAN and literature there cited. On infallibility see the article by Toner in the *Catholic Encyclopedia* (vol. vii. 1910), and works by Manning, Gibbons, Rivington, Ryder (against Littledale), Chapman (against Gore). Salmon's *Infallibility of the Church* (1889) discusses the doctrine controversially from the Protestant point of view; and see Mirot in Hauck-Herzog (1908). See also BASEL (COUNCIL OF), ACTON, DÖLLINGER, OLD CATHOLICS.]

Infamy, in Law, was a stigma attaching to the character of a person so as to disqualify him from being a witness. It was distinguished into infamy of fact and infamy of law. Infamy of fact results from a depraved course of life and abandoned character; of law from the sentence of a court finding the person guilty of any crime to which the character of infamy attached. Since 1843 it has not been possible to exclude a witness on the ground of infamy, though questions as to character and as to crimes committed by a witness may be asked with a view of affecting his credibility.

Infant, in English law, is a term which includes all persons under the age of twenty-one. Such persons are subject to special rules of law, which may be summarised as follows:

(1) *Crime*.—A child under seven cannot be convicted of crime; a child between seven and fourteen can be convicted if it is shown that he knew the nature of his act. A boy under fourteen is presumed incapable of rape.

(2) *Marriage*.—Boys under fourteen and girls under twelve cannot contract marriage. As a general rule, infants of marriageable age require the consent of parents or guardians to marry; but the absence of such consent does not affect the validity of a marriage actually solemnised. A person procuring the marriage of an infant by fraud forfeits any property which accrues to him or her from the marriage.

(3) *Property and Contract*.—An infant may acquire and dispose of property, enter into contracts, and carry on business; but he is privileged to repudiate liability for his acts, except in certain cases. Contracts for necessities (i.e. for things suitable to the infant's position in life) are binding

on him; and settlements, &c., executed with the approval of a judge, in terms of certain acts of parliament, are also binding. On coming of age an infant may confirm or rescind any act by which he has acquired or disposed of property during infancy; if he continues to hold property acquired, he must perform obligations connected with it: if, e.g., he has acquired shares in a company, he must pay calls on them. If he has entered into a continuing contract (e.g. a contract of partnership), he is taken to have confirmed it, unless he rescinds and ceases to take the benefit of it within a reasonable time. As for his other contracts, he might formerly have confirmed them by an *express* ratification; he is now precluded from doing so by the Infants' Relief Act of 1874, which enacts that no action shall be brought on the ratification of a promise made during infancy. No will made by a person under twenty-one is valid. An infant may bring an action by his *prochein ami* or next friend (usually his father, if living). If an action is brought against him, a guardian *ad litem* may be appointed. A parent or guardian is not liable for the debts of an infant, unless he has expressly or by implication contracted to pay them. An infant may contract as agent for a person of full age; in this case his acts are regarded as the acts of his principal.

In Scotland the law differs in many respects from the law of England on this subject. The term infant is not used at all in a technical sense. All persons, if male, are in legal strictness called pupils till fourteen, and if female, till twelve; and from fourteen or twelve to twenty-one they are technically called *minors*. In general, the contracts of a pupil are absolutely void, and he is under the care of tutors, who are either his parents or others appointed by the court. A minor, on the other hand, may enter into contracts; but if they are to his lesion or prejudice he can reduce or set them aside any time within four years after majority. Moreover, if a minor go into trade, his contracts bind him, as they do other persons. Further, a minor can make a will or testament, operating on his movable estate, though he cannot alienate his heritable estate in like manner. The four years which are allowed to him after majority to consider whether he will set aside contracts are called *quadrenniū utile*; and if he can prove lesion he is in that period entitled to restitution. In Scotland, also, a minor may marry as freely as if he were a major, and, indeed, he is in general his own master, or *sui juris*, at the age of fourteen (a female at twelve). See the article AGE.

Infant, FEEDING OF. When the health and strength of the mother admit of it, there is no doubt that the food provided by nature is far the best suited for infant nourishment. In this case the child should be fed entirely on breast milk for the first six or eight months at least, and partially during the next month till it is weaned. If prolonged beyond the ninth or tenth month, nursing is usually injurious both to mother and child, though it is often continued because of the idea that it tends to prevent pregnancy. If from any cause the mother is unable to nurse her infant, some form of artificial feeding must be devised. The old practice of finding a woman whose child was about the same age as the infant requiring nutriment, and who would act as a 'wet-nurse,' is now seldom adopted. Either fresh milk suitably modified or one of the specially prepared infants' foods may be used. The latter have all the disadvantage that they are devoid of certain necessary vital principles, so that if they be used to the complete exclusion of fresh food, the infant is liable to suffer from certain diseases, of which scurvy and rickets are the chief. Milk, on the

other hand, is liable, unless it is sterilised, to contain the germs of certain infectious diseases, of which the tubercle bacillus is the most formidable.

Goats' milk and asses' milk have both been recommended as more nearly resembling human milk than cows' milk does; but as they are generally difficult to procure while cows' milk is abundant, the latter must in most cases be employed. The differences between the mother's milk and cows' milk must be recognised, and allowance made for these in the feeding of young infants. Cows' milk contains much less sugar, slightly more fat, and considerably more albuminoids than does human milk. Further, under the action of the gastric juice, cows' milk forms a firmer clot than human milk. To 'humanise' the milk of the cow some such procedure as the following should be adopted: The milk should be diluted with an equal quantity of water, and to every eight ounces of the mixture should be added two ordinary teaspoonfuls of milk-sugar pressed level with the edge of the spoon, one tablespoonful of cream, and one tablespoonful of lime-water. The lime-water has the effect of softening the curd which forms in the child's stomach. The quantity of this dilute milk required by the infant at first is from two to three tablespoonfuls at each feed, making, if ten feeds be given, from ten to fifteen ounces in twenty-four hours. During the second and third weeks this amount should be nearly doubled, and the quantity of food gradually increases as the child gets older, the number of feeds at the same time gradually diminishing, as the child can take a greater bulk at each meal. From the third to the fifth month the intervals between the feeds should be three hours, the child should not require more than one feed in the night—that is, between 10 P.M. and 7 A.M.—and should have about five ounces at a time. After the sixth or seventh month, when the teeth begin to appear and the child can chew and digest starchy food, bread may be added to the milk, and rusks or crusts may be given to exercise the teeth. After the eighth month five meals daily should be enough, and of these, two should consist of farinaceous food, well cooked, such as milk-puddings of farola or ground-rice, oat-flour porridge, &c.; a little later for artificially fed infants, or when weaning is taking place for breast-fed babies, a lightly boiled egg or a cup of clear soup may be given as one of the meals. After the end of the first year the range of the diet may be gradually widened, potatoes, meat-broth, fish, chicken, and well-boiled vegetables being gradually added, but solid meat should be withheld till the second year has been completed.

It is very important to the infant that the meals should be given regularly; to feed the child every time it cries merely overloads the stomach, and produces or increases indigestion and colic. The bottle in which milk is given is a matter requiring great attention. It should be kept scrupulously clean, and should be sterilised daily by rinsing with boiling water or steeped in boracic acid solution, two bottles being used, and steeped on alternate days. Sterilisation of the milk is important in the case of weakly children, and during the prevalence of summer diarrhoea and of infectious diseases. By this means also the risk of the child contracting tuberculosis from milk is avoided. This may be effected by simply bringing the milk to the boil in a pan for a few minutes, or one of the special forms of steriliser may be used. When ordinary milk disagrees, it may be predigested by the use of zymine powders, or some change may be made in its concentration, or it may be replaced by one of the many artificial foods on the market. In the latter case especially, the child is benefited by

getting occasionally a small quantity of fruit juice, either of orange, grape, or prune.

Infante (from the Lat. *infans*, 'an infant'), the title given in Spain and (formerly) Portugal to the princes of the royal family, the corresponding title of *INFANTA* being given to the princesses. Since 1388 the heir-apparent to the throne in Spain has been styled the Prince of Asturias. The heir-apparent in Portugal, until the separation of Brazil from the mother-country, bore the title of Prince of Brazil. The personal domain of an *Infante* or *Infanta* is called the *Infantado*.

Infanticide, or the murdering of infants, was common in ancient times, and still prevails in some barbarous communities. The practice existed in Greece and Rome, and even found defenders in Plato and Aristotle. The latter in his *Politics* said the law should forbid the nurturing of the maimed, and, where a check to population is required, abortion should be produced before the quickening of the infant. In Sparta, as in other Greek states, the law directed that when a child was born the father should carry it to an appointed place, there to be inspected by the elders of the community. If it was a promising child, they returned it to its parents to be educated; otherwise it was thrown into a cavern at the foot of Mount Taygetus. In ancient Rome the Twelve Tables directed malformed infants to be immediately destroyed, and by the *Patria Potestas* the father had an absolute power over his children extending to life and death; but the rigour of the paternal law as regards both the killing and the sale of infants was mitigated by public opinion, and later also by legislation. Among the Norse the child's life hung in the balance till the father handed it to the nurse to be reared. If it was weak or malformed, or if the father disapproved of its living, the child was killed by exposure to the weather and to wild beasts. According to Caesar the Gauls were invested with the power of life and death over their children, and so late as the 13th century the Poles killed imperfect children. Amongst the Arabs it required an ordinance to prevent the crime of killing children lest the parent should be reduced to want, and this element of anxiety for the father's independence and comfort entered largely into the calculations of many states, barbarous and civilised, with regard to their posterity. The Arabs buried female infants alive.

In modern times infanticide prevails only amongst barbarous or semi-civilised nations, and even amongst these the increased intercourse with civilised states is gradually stamping out the practice. Until comparatively recent times child-murder prevailed throughout the whole of the South Sea Islands. In the Fijian island of Vanua Levu, or some parts of it, the infanticide reached, till the middle of the 19th century, a half and in others two-thirds of the child population. Amongst the Hindus the practice of destroying children, especially females, prevailed to a fearful extent, until it was checked under the Marquis of Wellesley's rule (1798-1805). The practice was forbidden by the Vedas; but, in consequence of the expense and the disgrace attached to girls remaining unmarried, the practice prevailed amongst the Rajputs—who destroyed all females except the first-born—and the native races. The methods of killing were poisoning by pills of tobacco, drowning in milk, smearing the mother's breasts with opium, and plastering the mouth with cow-dung. Notwithstanding the Koran, the Mohammedans were inclined to the practice, but effected their object by means of abortion. Efforts began to be made towards the close of the 18th century, amongst others by Jonathan Duncan and Major

Walker, for the suppression of the practice, and in 1853 these efforts were at last crowned with success at a durbar arranged for by Lord Lawrence. It was thought expedient to continue a system of surveillance by the police in some districts, and to institute a system of average numbers in families, which concentrated their vigilance upon those families which reached the lowest average. Amongst the Japanese the father had, but has not now, absolute power of life and death over his children. In China infanticide was, and in the remoter parts of that vast country still is, common. One of the causes here is the right possessed by Chinamen of periodically repudiating their wives. Sometimes the infants were stifled by the midwives at birth, and sometimes they were cast into a neighbouring stream, where in some cases they were humanely kept afloat by a gourd, so that they might be saved from destruction by any compassionate person who might feel disposed. In early missionary times it was a part of the duty of missionaries to pick up and rear, or entrust to others for the purpose of rearing, the waifs who had been abandoned through the avarice, poverty, or callousness of their parents.

In nearly all the cases mentioned infanticide was prompted by religious or economic reasons, or indulged in from caprice or indolence; and it was permitted in deference to the power with which in primitive communities as well as in advanced states like Greece and Rome the father was endowed. Modern civilisation deals very differently with the subject. In all European states, although they differ widely in their treatment of infanticide and cognate crimes, human life is from its first to its last hour held sacred, and whoever puts an end to it is a murderer. Almost the only motive which in such countries now leads to infanticide is that of shame—the parents incurring the risk of committing child-murder to escape social disgrace. The efforts therefore of legislators and criminal lawyers on the one hand have been directed to the repression of abortion, concealment of pregnancy, and murdering the new-born infant, and of philanthropists on the other to remove temptation to commit the graver crimes by providing Foundling Hospitals (q.v.), where the offspring of sin may find a refuge. See also ILLEGITIMACY.

In England and Scotland the inexcusable killing of infants is theoretically murder, and the only excuse for killing the foetus is the safety of the mother; otherwise, Abortion (q.v.) is a criminal offence. The concealment of birth is also a criminal offence; see BIRTH (CONCEALMENT OF). The destruction of children may be effected negatively by not supplying food and clothing, as well as by the positive act of wounding or ill-treating; and if a parent or other person who is bound by law to supply food and clothing to the child refuses or neglects to do so, thereby causing its death, such refusal or neglect amounts either to murder or manslaughter, according to the circumstances. Moreover, the unlawful abandoning or exposure of any child under the age of two years, whereby the life and health of the child are endangered, is a misdemeanour punishable with three years' penal servitude. Where a person is charged with the murder of a very young child it is essential to prove that the child was in life. Under a statute of James I. there were presumptions against the mother, but in 1803 the trials for offences of this class were placed under ordinary rules of evidence. The presumption which now obtains that every new-born child found dead was born dead is believed by certain jurists to have encouraged infanticide. The test of a child being born alive is not that it breathed, or that the umbilical cord was severed; but the entire child must be

born and have an independent circulation. Hence, if a man strike a woman with child, so as to cause the death of the child, he is neither guilty of murder nor of manslaughter of the child; because to constitute these crimes the person killed must be 'a reasonable creature in being, and under the king's peace.' In trials for the murder of infants the question whether the child was fully born, and so the subject of murder, generally depends to a large extent upon medical evidence. The above offences in reference to infanticide, are punished in a similar manner in Scotland, where, though the killing of a completely born infant is murder, a verdict of culpable homicide is frequently returned. Concealment of pregnancy is the usual charge under 49 Geo. III. chap. 17.

It has been stated that every day an inquest is held upon the bodies of children destroyed through the design, the neglect, the ignorance, or the mental infirmity of the mothers. Even when the act may fairly be regarded as a crime, its enormity is generally greatly lessened in the eye of the law by the consideration of the physical condition and moral disturbance of the parent.

The Children Act, 1908, obliges those who undertake for hire to keep infants under the age of seven years, for a longer period than forty-eight hours, to notify the local authority as to the names, &c., of such children, give notice if the children leave their charge, and inform the coroner or procurator-fiscal of such infants' deaths. They are also under obligation to keep sanitary houses. By the same statute any person over sixteen who wilfully ill-treats, neglects, abandons, or exposes a boy under fourteen or girl under sixteen years of age under his care, or causes or procures this to be done, in a manner likely to cause the child unnecessary suffering or injury to its health, is guilty of a misdemeanour, and is liable to £100 of fine or imprisonment for two years, or to both. Lesser penalties are inflicted on summary conviction. The punishment may be increased where the offender is proved to be interested in the death of the child. See CHILDREN (CRUELTY TO), and BURIAL SOCIETIES.

Infantry. See ARMY.

Infant Schools. Pastor Oberlin (q.v.) may be regarded as the founder of infant schools. He appointed women in his own parish to assemble the little children between the ages of two and six, to interest them by conversation, pictures, and maps, and to teach them to read and to sew. The first infant school attempted in Great Britain was in connection with Robert Owen's socialistic establishment in Scotland. The education and training of young children were matters of great interest and study to Pestalozzi (q.v.). His system was adapted to English requirements by the Home and Colonial Infant School Society, founded in 1836. This society did excellent work in training teachers and instituting model infant and juvenile schools. But the most successful systems of educating quite young children are the Kindergarten (q.v.) and Dr Montessori's. See EDUCATION.

Infection. The grounds for believing that each of the large class of communicable diseases depends upon the presence within the body of a distinct living organism have already been stated (see GERM). The manner in which each of these supposed organisms behaves in originating fresh cases of disease is, however, almost as characteristic as the effects it produces on the body.

(1) In malaria the organism is a lowly type of animal life which undergoes cycles of development in the blood of the 'host,' each new cycle being associated with an attack of ague. The actual

means of transmission is by a mosquito, which carries the parasite from person to person, and in which the parasite undergoes a stage of development. The parasite of sleeping sickness is similarly carried by the tse-tse fly, in which the parasite undergoes a stage of its development. The same principle applies to infection with tapeworm and other large forms of parasite, which undergo development in an 'intermediate host.'

(2) Intermediate between these and the more characteristic infectious diseases is a group of which cholera and typhoid (enteric) fever may be taken as types. Here the infectious material has its origin chiefly from the dejecta of the patient, and is carried from the sick to the healthy in contaminated water, milk, food, by flies, by dust, &c. Epidemics, e.g., of scarlatina are in this manner sometimes traced to workers in dairies suffering from the disease.

(3) The largest and most typical class includes typhus, smallpox, measles, scarlet fever, whooping cough, and many others. In all these the disease is directly and immediately communicable from the sick to the healthy. But there are striking differences in the conditions under which infection usually takes place. The poison of typhus, the dreaded 'jail fever' of past times, is probably carried by lice, and the danger of its spreading can be much diminished by cleanliness and free space. In smallpox the infection can retain its vitality for years on the walls of a room, or in the artificially dried discharge from the pustules; in scarlet fever it may exist for many months in articles of clothing. Measles is most infectious in the early stage, when it presents merely the symptoms of a bad cold; scarlet fever infection is probably at its worst after the rash is well developed.

(4) The question of 'carriers' of disease—i.e. persons who harbour the organism though not themselves suffering from the disease—is one of great practical importance. Enteric fever, diphtheria, and cerebro-spinal meningitis are believed often to be spread in this way.

(5) The last group consists of those diseases in which the poison is not carried to a distance or through an intermediary, but requires to be directly inoculated to produce the disease—e.g. syphilis and hydrophobia.

This classification of diseases believed to be dependent upon organisms, though practically convenient, cannot be considered a strictly accurate one; for many of the diseases in group 3, perhaps all, can be propagated by inoculation, and the infection of some may be able to develop outside the body and behave like those in group 2.

With regard to the commoner infectious diseases, some of the most prevalent and most serious have been scheduled in the Infectious Diseases Acts as notifiable in Great Britain. These diseases are smallpox, cholera, diphtheria, erysipelas, scarlatina, and the fevers known as typhus, enteric, relapsing, and puerperal. Others of the diseases, such as measles, are included from time to time by local authorities to whom the occurrence of a case of any of these diseases must immediately be notified. In regard to prevention of infection, the means used refer specially to children, who are more liable to contract infectious diseases than adults, and measures taken apply particularly to schools. It is usual to insist that persons who have contracted infectious diseases shall not mix with the public again until they are completely recovered and until a definite period, differing in the various diseases, has elapsed. After healthy persons have been 'in contact' with the more serious of these diseases, such as diphtheria, scarlatina, and small-

pox, they must remain in quarantine for periods exceeding the longest possible incubation period; and it is essential that the clothing of the suspected person should be disinfected at the beginning of the quarantine period. For isolation after contact with the slighter diseases, such as measles, German measles, chicken-pox, whooping cough, and mumps, various regulations are in force in different places; and complete isolation throughout a period corresponding to the period of incubation is not so rigidly enforced as a rule in the case of those who have already suffered from the disease in question. Such children are generally allowed to continue attending school, but are carefully inspected each day for some time before and after the end of the usual period of incubation so that signs that the disease has been contracted may be observed at once, and in this case the child is immediately isolated.

Enough has been said to show the complexity of the problems, both practical and scientific, presented by the subject. As to the Infectious Diseases Notification Acts and other cognate matters, see HYGIENE, DISINFECTANTS, CONTAGIOUS DISEASES ACTS, and the articles on the several diseases.

Infefment, or **SASINE**, a Scots law term, used to denote the symbolical giving possession of land, which was the completion of the title, the mere conveyance not being enough. The instrument of sasine was the notarial instrument embodying the fact of infefment. The old ceremony, which was not abolished until 1845, was thus performed. The bailie of the superior of the lands, the attorney of the vassal, a notary, and two witnesses proceeded to the lands in which sasine was to be granted. The attorney delivered to the bailie the superior's precept of sasine, and required him to perform his duties. The bailie delivered the warrant and relative deeds to the notary, who read and published them to all present. The bailie thereupon delivered the symbols of possession, sometimes a pen, to the attorney, and the attorney then took instruments in the hands of the notary by giving him a piece of money. But now the necessity of a separate formality is unnecessary, it being sufficient to register a conveyance in the register of sasines in Scotland. In Scotland an *infefment in security* is a temporary infefment to secure payment of some debt; and an *infefment of relief* is a similar security to relieve a cautioner.

Infinite. In philosophy, infinite is that which is without any limitation, and, like absolute and unconditioned, is used especially of the Infinite, of God. As to our knowledge of the infinite, some (as Hamilton and Mansel) hold that the idea is purely negative; Descartes affirmed that the idea of the infinite was not merely the idea of an objective reality, but is implied as a necessary condition of every other. See ABSOLUTE, CONDITION, RELATIVITY OF KNOWLEDGE; Hamilton's *Discussions*, Mansel's *Limits*, Calderwood's *Philosophy of the Infinite*, Spencer's *First Principles*.

In mathematics, the term infinity and the phrases infinitely great and infinitely small are of constant occurrence; and the symbol ∞ is usually said to denote a magnitude infinitely great, the symbol 0 a magnitude infinitely small. Are these magnitudes infinitely great and infinitely small to be reasoned about in the same way as ordinary finite magnitudes? Are these symbols ∞ and 0 to be treated in the same way as ordinary algebraic symbols, a , b , x , y , &c.? With respect to the symbol 0 there seems at first sight to be little difficulty, for we are accustomed to regard it as denoting the absence of all quantity, or as the result obtained by subtracting any finite quantity

from a quantity equal to it. It is found convenient however, though it would be impossible to explain in short compass the grounds of the convenience, to give another meaning to the symbol 0. The new meaning will perhaps be understood from the following illustration. Take the algebraical expression $\frac{1}{x}$, and suppose x capable of increasing so that it may become greater than any assignable quantity; then the value of $\frac{1}{x}$ will diminish and become less than any assignable quantity, and the limit towards which it tends, that is to say, the value from which it may be made to differ as little as we please, is symbolised by 0. The same expression will enable us to give a meaning to the symbol ∞ . Suppose x capable of diminishing so that it may become less than any assignable quantity; then the value of $\frac{1}{x}$ will increase and become greater than any assignable quantity, and the limit towards which it tends, that is to say, the value from which it may be made to differ as little as we please, is symbolised by ∞ . The symbols 0 and ∞ therefore, denoting the limits towards which certain variable quantities tend when particular suppositions are made, cannot be used absolutely like the symbols denoting finite quantities: because $a \div a = 1$, it would be erroneous to conclude that $0 \div 0 = 1$ or $\infty \div \infty = 1$. Expressions such as $0 \div 0$, $\infty \div \infty$, $\infty - \infty$, $0 \times \infty$, ∞^0 , and some others are called indeterminate forms; for methods of evaluating them, see Chrystal's *Algebra*, chap. xxv., or De Morgan's *Differential and Integral Calculus*, chap. x.

Infinitesimals is the name applied to the method adopted by Leibniz as the foundation of his Differential Calculus. Leibniz considered magnitudes as composed of infinitely small elements or infinitesimals. Those elements which are infinitely small compared to any finite magnitude are infinitesimals of the first degree; those which are infinitely small compared to infinitesimals of the first degree are infinitesimals of the second degree; and so on. The principle of the method briefly stated is that two finite magnitudes are equal if they differ only by an infinitely small magnitude. Though the results obtained by the application of infinitesimals are seen to be always in accord with the results obtained by other methods, and a method which always leads to correct conclusions must be logically sound, yet the fundamental principle does not at first sight seem rigorously exact, and the method looks as if it were merely one of approximation. In consequence it has now come to be usual to found the calculus on the doctrine of limits.

Infinitesimal Calculus. See CALCULUS.

Infirmaries. See HOSPITALS.

Inflammation is the most important of all the morbid processes that fall under the notice of the physician or surgeon. The most obvious symptoms or phenomena of inflammation, when it attacks an external or visible part, are pain, redness, heat, and swelling. If a healthy man gets a splinter of wood or any other foreign body imbedded in any fleshy part he begins to experience pain at the part, and this is soon succeeded by redness of the skin. In its early stages the process is known as irritation; but soon, if the foreign body be not removed, the pain and redness increase, and are accompanied by a firm and extremely tender swelling at and around the spot, and a sense of abnormal heat. These purely local symptoms are succeeded, if the inflammation reach a certain degree of intensity, by a general derangement of the vascular and nervous systems, to which various names, such

as constitutional disturbance, symptomatic or inflammatory fever, &c., have been applied.

Numerous observers have attempted to trace the exact phenomena of inflammation by microscopic examination of the transparent parts of animals in which the process has been artificially excited. From observation made on the web of the frog's foot and other transparent parts of animals by Wharton Jones, Paget, Cohnheim, Burdon Sanderson, Ziegler, Lister, and many others, the main features of the process are now well known.

In inflammation of moderate severity the blood-vessels of the part are seen to dilate, and the current of blood through them, at first sometimes a little accelerated, becomes much slower than the normal. In consequence of this retardation the white blood-corpuscles, being somewhat sticky in consistence, fall out of the central stream, and drag along the sides of the vessel, where, as the inflammation increases, they are arrested. Then follows the most remarkable part of the process. Minute buds are seen to form on the outside of the walls of the veins and capillaries, each one corresponding to a white blood-corpuscle in the interior. These buds grow larger at the expense of the corpuscles, which thus pass through the wall of the vessel without any break in its continuity; and the migration continues till the tissue around the vessels is crowded with corpuscles. At the same time an abnormal quantity of fluid exudes through the walls of the blood-vessels, and in part coagulates, forming with the corpuscles what is known as coagulable or plastic lymph. From the capillaries red as well as white blood-corpuscles pass into the tissues. If the inflammation be more intense complete arrest of the flow of blood in the vessels (stasis) takes place.

We may now consider the explanation of the cardinal symptoms of inflammation. The *redness* depends upon there being more blood than usual in the blood-vessels of the affected part; sometimes also upon the occurrence of hemorrhage in the inflamed tissue. The *swelling* depends in part upon the distension of the blood-vessels, but mainly upon the effusion of fluids and blood-corpuscles above described. These are termed the *products* of inflammation; and many changes, some of a reparative nature and others of an injurious tendency, depend upon their presence. The *pain* may vary from mere discomfort to intense agony. It is probably due to compression of the sensory nerves of the affected part by the dilated vessels, and the exudation. It is often throbbing. There is usually most pain in those parts in which the tension produced by the swelling is the greatest, as in bone, serous and fibrous membranes, &c. The pain occurring in inflammation is always aggravated by pressure, and by this means the physician can often distinguish between inflammatory and non-inflammatory disorders. The *heat* is seldom so much increased as the sensations of the patient would lead him to believe; it does not rise above the maximum heat of the blood in the interior of the body. This increase of heat depends upon the increased flow of arterial (or highly oxidised) blood to the part.

Special changes take place in different tissues and organs. Thus in serous cavities, like the pleura and peritoneum, and in joints, there is apt to be an effusion of excess of fluid; in the case of bone, the interference with the circulation is liable to cause death of a mass of bone and its separation as a sequestrum with subsequent trouble, &c.

The further course of inflammation is much more variable. The most favourable termination is *resolution*, where the products of the inflammation are gradually removed by the lymphatics, and the tissue returns to its normal state. If the exuded

blood-corpuscles accumulate in large amount (*suppuration*) they form an Abscess (q.v.), and must in general be evacuated before cure can take place. If the inflamed tissue be superficial its outer layers may die and be thrown off (*ulceration*), leaving a sore which heals by Cicatrisation (q.v.). If the inflammation be severe and extensive, Gangrene (q.v.) or *mortification* may ensue.

In the return to health of inflamed tissues, where neither resolution nor death of the patient has taken place, formation of new tissue is necessary to fill up the gap which is left by suppuration or ulceration. This is effected mainly by the action of the small cells present in the exuded material, which under suitable conditions becomes gradually organised into fibrous tissue, bone, &c.; but the restoration of the epithelial covering, where a breach in the surface either of skin or mucous membrane has occurred, is effected only under the influence of epithelial cells present at the end of the gap. The process is essentially similar to the healthy repair of broken bones (see FRACTURE), or incised wounds, though the term inflammation is not generally applied to these cases. It is thus that parts recently severed from the body may be sometimes replaced and still live. The success of the Taliacotian operation, by which a new nose is engrafted in the position of that which had been lost, of the operation of injecting a stimulating fluid into cystic tumours, with the view of setting up adhesive inflammation, and of various other surgical operations, essentially depends upon the property of organisation possessed by inflammatory exudation, or closely allied products. Although the organisation of plastic lymph is thus essentially a conservative and reparative process, it leads in many cases to untoward results. Thus, when a serous membrane (e.g. pleura, pericardium, peritoneum) is inflamed, the exudation between its contiguous surfaces often becomes transformed by the same process into fibrous tissue, forming layers or bands which seriously interfere with the functions of the organs involved (lung, heart, intestine, as the case may be) after the inflammation has subsided. In inflammation of the iris the pupil may be rendered irregular or immovable, or may even be closed up by inflammatory exudation. In endocarditis, or inflammation of the lining membrane of the heart, exudation may be deposited in wart-like masses on the valves, and may thus occasion some of the worst forms of cardiac disease.

The causes of inflammation are very various. Among predisposing causes must be reckoned any condition which lowers the vitality of the whole body, or of any particular part of it. The most obvious exciting causes are mechanical violence, chemical irritants, excessive heat or cold, producing injury of a part of the body which leads directly to inflammation in that part. Less obvious, but not less certain, is the effect of exposure to cold in exciting inflammation of internal organs. But of all the causes the most important undoubtedly, though they were only recognised within the last three decades of the 19th century, are micro-organisms—bacteria, &c. (see GERM). Besides the numerous *specific* diseases attended by inflammation of various organs and tissues proved or believed to be due to these bodies, many forms of what is known as *simple* inflammation—e.g. acute abscess—have been shown to be associated with them. Some authorities go so far as to say that no true inflammation can take place without them; and though this opinion has not been proved, it is certain that almost all the most severe forms of inflammation are characterised by the presence of some form of micro-organism.

The inflammatory diseases of the most important organs are described under their specific names,

and, as a general rule, the termination *-itis* is employed to indicate an inflammation. Thus, peritonitis signifies inflammation of the peritoneum; iritis, inflammation of the iris; &c. Inflammation of the lungs, however, is usually known as pneumonia instead of pneumonitis, and of the pleura as pleurisy instead of pleuritis. See PNEUMONIA, PLEURISY, ENTERITIS (for inflammation of the bowels), PERITONITIS, STOMACH (for gastritis), LIVER (for hepatitis), EYE (for iritis), BRAIN, &c.

It is unnecessary to enter into the consideration of the treatment of inflammation further than to remark (1) that if possible we must remove its exciting cause, which can seldom be done except when the inflammation is external; and (2) that the patient should be placed on a simple and unstimulating diet (which implies a total abstinence from solid animal food and stimulating drinks). The medicines chiefly employed are purgatives, preparations of mercury, quinine, phenacetin, and other coal-tar derivatives, and preparations of opium; while, as external applications, hot fomentations or poultices (sometimes applications of cold water or ice are preferable), and counter-irritation by means of blisters, sinapisms, iodine, &c., are often of service.

Infection. See GRAMMAR.

Inflorescence. This term is applied by botanists in a concrete and special, as well as in an abstract and general sense—i.e. first to any single group or natural aggregate of flowers arising upon a common main axis, and secondly to the various modes or principles of floral arrangement themselves. Despite that endless superficial diversity upon which the characteristic aspect of different species and larger groups so much depends, these apparently indefinite variations may readily be reduced to a small number of easily intelligible types. For, while the earlier botanists naturally tended to develop a nomenclature corresponding to the multiplicity of outward forms which inflorescences acquire, the progress of research has simplified this by centering attention upon the few and simple modes of branching by which they arise. We naturally set out with any plant of

Fig. 1.

a, raceme of lily of the valley (*Convallaria*); b, corymb of candy-tuft (*Iberis*); c, umbel of fruits of fennel (*Foeniculum*); d, spike of vervain (*Verbena*); e, head of fruits of dandelion (*Taraxacum*); f, *Dorstenia*; g, fig (*Ficus*) in vertical section.

which the axis continues to grow indefinitely, but of which a number of secondary axes arising in the axils of the leaves are developed as flowers. When the pedicels of these flowers tend to reach a moderately equal length the inflorescence is known as a *raceme* (fig. 1, a); or when the process of floral development arrests them, so that the flowers are practically sessile, we have a *spike* (fig. 1, d). The

growing point of most racemes and spikes, however, tends to be checked by the reproductive stress, and the axis thus frequently ends, or rather seems to end, in a terminal flower. Good examples of this essentially racemose or spicate type are furnished by many Liliaceæ, Scrophulariaceæ, &c.—e.g. Kniphofia, foxglove, mullein, &c. Even such a curious inflorescence as that of the pine-apple may now easily be interpreted as a greatly condensed spike of fruits, crowned by its leafy growing point.

The shortening of the main axis of a raceme may take place after ordinary development has begun, so that the upper internodes are much less developed than their predecessors. The pedicels of the younger flowers naturally share the same arrest of development, and thus it is that the comparatively long pedicels of the lower flowers place them on much the same level as the higher ones, and even as the summit of the axis. This variety is known as the *corymb* (fig. 1, *b*), so familiar in the candy-tuft. When all the internodes are so shortened that the pedicels arise from practically the same level, we have the *umbel* (fig. 1, *c*), so characteristic of the Umbelliferæ.

Suppose this vegetative arrestment and floral precocity to be continued still further, internodes and pedicels alike become arrested, and the result is a crowded cone or excessively shortened spike of sessile flowers. By continuing the same process which gave us the corymb, the cone necessarily tends to appear more and more depressed through the more rapid upgrowth of its lower portions; thus we have that characteristically expanded axis, so compactly set with florets as to resemble at first sight a single flower, familiarly known as the head or capitulum of the Composites (fig. 1, *e*). The spiral arrangement of the florets so obvious in a sunflower is simply that of the depressed cone, which we may again draw out in imagination into the corymb, the spike, or the raceme, with which it is in principle identical.

A capitulum fundamentally similar may, however, be evolved in a slightly different way, by the more or less complete arrestment of the secondary axes of an umbel. Hence it is that a few umbelliferous plants, like *Astrantia*, or still better the sea-holly (*Eryngium*), &c., come to present that appearance which so often induces the beginner to confuse them with Composites.

But, since it is manifest that the same embryonic shortening may occur in any type of inflorescence whatsoever, it becomes evident that we must reserve the term capitulum for the type of inflorescence presented by the Composite or Scabious, leaving the various superficially resemblant forms or *pseudo-capitula*, as of sea-holly already referred to, or those of sea-pink, of bergamot, &c., to be separately analysed according to their true origin.

Returning, then, to the capitulum proper, we must continue to keep clearly in view that conception of vegetative growth (as reaching its maximum rate only at some distance behind the growing point) which may be actually verified by measurements of any growing shoot or root. The conical axis thus not only tends to broaden and flatten, but its lower portion must at length overtake the apex, and a perfectly flat receptacle, as in some species of *Dorstenia*, results. The margins next outgrow the apex, and the cone is now becoming a shallow saucer (other species of *Dorstenia*, fig. 1, *f*). The saucer next becomes a cup, or even flask; and the remarkable hollow inflorescence of the fig (fig. 1, *g*) is thus seen to be morphologically akin to the capitulum, and through this by the corymb even to the original raceme itself.

The study of vegetative branching (see BRANCH) has, however, shown us that we may have to do

with compound or sympodial axes as well as simple or monopodial ones. That is to say, in our primary axis the growing point may perish, leaving, however, of course, all the more opportunity for the development of the secondary axes latent in its lateral buds. This disappearance of the primary growing point, having once set in, soon works back, until we have it occurring immediately after the development of the first lateral bud. This then readily takes its place for practical purposes, just as a larch or pine which has lost its top renews it by the upgrowth of a branch. But the new axis dies in turn after giving birth to its successor, and so on; thus the *false axis* or *sympode* is formed. Inflorescences of this type are known as *cymes*. The simplest in principle is that of the Day-lily (q.v.). It is commonly known as the *helicoid cyme* (fig. 2, *h*), since the origin of the new axes winds on in the same spiral order as that of the leaves upon the primary axis itself. The distinction from a raceme is, however, easily made when we notice that the so-called bracts are not really bracts at all, but are more or less opposite to the flowers; being really only the axillant leaves of the next axis, which bears its flower only after producing a leaf with the bud of its successor.

But in other cases the spiral may change its direction with each new axis, and the false axis thus assumes a very different appearance, that of the *scorpioid cyme* (fig. 2, *i*), of which the classical example is furnished by the Boraginaceæ (Goebel, however, regards these as unilateral racemes, and offers *Tradescantia*, *Echeveria*, &c. as more real types). This reversal of the spiral has been prettily verified by noting how in the scorpioid cyme of the Rock-rose (*Helianthemum*) the spiral of the calyx runs in an opposite direction in each successive flower.

So far we have been dealing with cymose inflorescences as arising in plants with alternate leaves: in opposite-leaved plants—e.g. Caryophyllaceæ and *Begonia* (q.v.)—the resultant form is necessarily very different. Let the growing point terminate in a flower as before; but since each of the two leaves immediately below is in an equally favourable condition, both as regards radiation and aliment, we have two secondary axes instead of one. Hence, instead of one secondary axis continuing in the line of the primary one, we have necessarily two of equal strength and divergent at an equal angle. The main axis thus at first sight

Fig. 2.

Diagrammatic representation of *h*, helicoid cyme; *i*, scorpioid cyme; *k*, dichasium.

seems to have forked, especially when the terminal flower disappears, just as in the false dichotomy so apparent in the branches of the lilac or mistletoe; and hence the old name of *dichotomous cyme*, which,

however, it is evidently necessary to correct, as *dachasium* (fig. 2, k), *biparous cyme*, or the like.

This inflorescence may undergo shortening; or in more physiological language remain more or less embryonic, as in most Labiatae (which, however, present all gradations, from the fully-developed cymes of *Hyssopus*, through the 'false whorls' or 'verticillasters' of the majority of genera, to the terminal pseudo-capitulum of *Bergamot*). The apparent umbel of geraniums and the pseudo-capitulum of the sea-pink have also this origin.

Not only modifications of these leading types, but various combinations, simple, compound, and complex, and in all degrees of reduction or exuberance, may also arise; the question of separating all the preceding types of inflorescence as *radial* from a small residuum as *dorsi-ventral* also presents itself. See Goebel's *Outlines of Classification* and Van Tieghem's *Traité de Botanique*.

Influenza (Ital., 'influence'; called in French *la grippe*), a disease of infectious nature occurring in wide-spread epidemic outbreaks, has been long recognised by medical writers. The popular application of the name to any severe cold in the head is not sanctioned by medical authority. Cullen called it *catarrhus e contagio*, but although, in most cases, it closely resembles ordinary catarrh, it presents certain points of difference from that disease. In addition to the ordinary symptoms of catarrh there is a sudden, early, and very striking debility and depression of spirits. This early debility is one of the most marked and characteristic signs of influenza. The mucous membranes (especially those of the respiratory organs) are much affected. The tongue is white and creamy, the sense of taste is lost, there is no appetite, the pulse is soft and weak, the skin, although at first hot and dry, soon becomes moist, and the patient complains of pains and soreness in various parts of the body.

In simple, uncomplicated cases convalescence supervenes in the course of a week or sooner; but influenza is very frequently conjoined with bronchitis or pneumonia, in which case it is much more persistent and dangerous. There is, moreover, an extreme proneness to relapse on the slightest exposure, even after the patient feels perfectly recovered.

Influenza affords an excellent example of an epidemic disease, a whole community being often attacked in the course of a few hours. A bacillus, described originally by Pfeiffer in 1892, is found in the bronchial secretion of many cases, and other investigators have described a minute 'filter-passing' organism in other outbreaks. Not unfrequently influenza follows close upon a sudden thaw; sometimes it is preceded by thick, ill-smelling fogs; but hot and cold, wet and dry weather have all been attended by severe outbreaks of the disease. Like cholera, influenza generally, but by no means constantly, follows a westerly direction, or one from the south-east towards the north-west.

The epidemic which prevailed during the winter of 1889-90 in most parts of the civilised world, the first of importance in Britain for nearly forty years, presented some points of difference from most of the previously recorded outbreaks. In particular, there was in many places a much larger proportion of cases without any catarrhal symptoms whatever than appears to have been observed before. Such cases present a close resemblance to Dengue (q.v.). In the epidemic of 1918 the catarrhal type was present in almost every case, and there was a great tendency to the onset of pneumonia, which underwent septic changes, and ended frequently in death. The mortality in this epidemic was very high.

The most important points in the treatment of influenza are to sustain the vital powers of the

patient and to prevent the onset of pneumonia. This is greatly aided by inhalations of steam containing creosote, menthol, Friar's balsam, and similar aromatic substances. He should be kept in bed; his bowels should be gently opened, his skin slightly acted upon, if dry; and, if the cough be troublesome, a mustard-poultice should be applied to the chest, and an expectorant mixture prescribed. Antipyrin and aspirin were during the epidemic of 1918 found very valuable in combating the feverishness and pain of the early stage. In persons of weak or broken-down constitutions, beef-tea, spirits, or strychnine must be given from the outset. The debility that often remains for a considerable period after the establishment of convalescence is best met by the preparations of iron, quinine, and strychnia.

Few diseases increase the death-rate to such an extent as influenza; more, however, in consequence of the great number of persons who are attacked in a severe epidemic than in consequence of its danger in individual cases. See EPIDEMIC, GERM.

In Forma Pauperis ('in the character of a poor person'). Persons are said to sue *in forma pauperis* when the law allows them to conduct lawsuits without paying fees to court-officers, counsel, or solicitors. In England a statute of Henry VII., affirming the common law, provided that such as would swear themselves not worth £5, except their wearing apparel and the matter in question in the cause, should be exempt when plaintiffs, but not when defendants, from the payment of court-fees, and should be entitled to have counsel and attorney assigned to them by the court without fee. They were further excused from costs when unsuccessful; a privilege which, according to Blackstone, amounted in former times only to the rather uncomfortable alternative of choosing between paying and being whipped. This indulgence, first confined to plaintiffs, was afterwards extended to defendants. It was at first restricted to the Common Law Courts, but afterwards adopted in the practice of the Equity and Probate and Divorce Courts. No one can sue *in forma pauperis* unless he is worth less than £25, or produces to the court applied to an opinion of counsel on his case, and an affidavit that the same case contains a full statement of the material facts. A suitor *in forma pauperis* is not entitled to costs unless by order of the court. In Scotland an act of 1424 established the poor's roll to secure a like privilege to poor persons there.

Information. See CRIMINAL LAW.

Informers, in English law, the person who sues for a penalty under some statute. In many statutes which define offences—not criminal, but savouring of criminality—encouragement is often given to persons who are willing to sue on behalf of the crown, the pecuniary penalty or part of it being given to the informer. This kind of action is called a *qui tam* action, from the use of the words *qui tam pro domino rege quam pro seipso*, &c. In criminal proceedings an accomplice who turns king's evidence, if accepted as a witness by the crown, is called an approver or prover. Ever since the days of the professional 'sycophant' at Athens the informer has been regarded as an odious character. In Ireland, owing to the unsatisfactory relations between the government and the people, almost any person who gives evidence against a prisoner runs the risk of making himself unpopular. In Chancery proceedings at the suit of the attorney-general the informer is called a relator. In Scotland an informer is the party who sets the Lord Advocate in motion in criminal prosecutions, and the Lord Advocate is bound to give up the name of the informer, who is liable in case of malicious prosecutions. See APPROVER, SPY.

Infusions are aqueous solutions of vegetable substances obtained without the aid of boiling. In this respect only do they differ from decoctions, in the manufacture of which boiling is resorted to. Infusions are prepared by digesting the vegetable substance (root, bark, &c.) in hot or cold water in a covered earthenware vessel. Cold water is preferable when the active principle is very volatile, or when it is desired to avoid the solution of some ingredient in the vegetable which is soluble in hot, but not in cold water. For example, in preparing the infusion of calumba cold water is preferable, because it takes up the bitter principle (which is the essential ingredient), and leaves the starch-matter undissolved. In most cases, however, boiling water is employed. Infusions are preferred to decoctions when the active principle volatilises at a boiling heat, as in the case of essential oils; or when ebullition readily induces some chemical change, as in the case of senna.

Infusions may also be prepared by percolation, a process which is extensively employed in the preparation of tinctures. When thus prepared they are less liable to decay than when prepared on the old system.

The fresh infusion, while possessing a finer flavour, is in danger of being superseded in pharmaceutical practice by the concentrated infusion. On account of the trouble and expense involved in making small quantities of the fresh preparations recourse is frequently had to the concentrated ones, which, when diluted with seven times their bulk of distilled water, more or less represent the fresh article. Where the active principle is a volatile one it is very difficult to retain the full aroma in the concentrated state, and to this question much pharmaceutical attention has been turned. The concentrated infusions contain from 20 to 25 per cent. of alcohol, which is essential for their preservation. The simple infusions may be preserved for a short time by the addition of a trace of chloroform.

Infusoria, a name given to several classes of active Protozoa, some of which appear in great numbers in stagnant *infusions* of animal or vegetable matter. The great majority are provided with vibratile locomotor processes of their living matter, usually in the form of cilia or flagella; and, though these may be retracted when the animal occasionally encysts itself, they are practically permanent, and express the predominantly active constitution of these cells. Most are microscopic, but many are readily seen when foul water is held in a glass vessel between the eye and the light. Yet there may be more Infusorians in a cup of stagnant water than there are people on the globe. Infusorians occur both in fresh and salt water, and a few are parasitic; they feed on vegetable or on animal matter, on bacteria or on one another, while some possessed of a green pigment, closely allied to, if not identical with chlorophyll, probably absorb carbonic dioxide after the manner of plants. Most Infusorians possess a 'mouth'—i.e. a special aperture through which the food-particles are wafted in by the cilia or flagella. As single cells, comparable to the units of ciliated epithelium in multicellular animals, to the active spores of plants, and to male cells or spermatozoa, they exhibit the usual protoplasmic structure and the central differentiation or nucleus. There is usually a definite rind, often with cuticular structures; and there are generally contractile vacuoles, probably excretory in function. Many Infusorians occur not as single individuals, but as members of a colony, the results of multiplication remaining clubbed together, and often forming masses easily visible to the unaided eye. They multiply with great rapidity by dividing into two, or by rapid

successive division into a larger number (spore-formation); and thus a single Infusorian, with favourable temperature and nutrition, may in four days become the ancestor of a progeny of a million, in six days of a billion, in seven and a half days of a hundred billions—weighing one hundred kilogrammes! If the life of the species, however, is to be sustained, conjugation or incipiently sexual union of two Infusorians (not of the same family) must occur, for if the descendants of one individual be left by themselves the whole family falls victim to 'senile degeneration,' and the members dwindle away. In many cases among ciliated Infusorians the researches of Maupas and others have shown that the conjugation of two forms means an interchange of nuclear elements; in other cases the two individuals fuse into one. When the two conjugates are of unequal size, as in the common Vorticella or bell-animalcule, it seems justifiable to call the smaller male and the larger female.

The classes included under the title of Infusorians are as follows, beginning with those ciliated forms to which zoologists often restrict the term.

Ciliata.—Infusorians characterised by the predominance of alternately bent and straightened motile processes known as cilia. The usual nucleus is accompanied by a second neighbour nucleus (para- or micro-nucleus), the elements of which are interchanged in conjugation. They are classified according to the relative position and size of their cilia. The slipper-animalcule (Paramecium), and Opalina parasitic in the intestine of the frog illustrate those which are more or less completely ciliated (Holotricha); the beautifully-coloured species of Stentor, the genus Balantidium, with one species parasitic in man, and the common Bursaria are among those with heterogeneous cilia dissimilar in size and form (Heterotricha); the stalked bell-animalcule Vorticella and its beautiful allies Epi-stylis and Carchesium, the jumping Halteria, with a girdle of springy, bristle-like processes, and Ophrydium, which multiplies into large hollow colonies, sometimes 5 inches across, have a special wreath of cilia round the mouth (Peritricha); and lastly, those with cilia restricted to the under surface are well illustrated by Euplotes, Oxytricha, and Stylonichia.

Flagellata.—Infusorians with a vibratile or undulatory flagellum, or with more than one, used for locomotor or food-catching purposes, including a vast number of forms, some of which are often called Monads, while others—e.g. Volvox—approach if they do not unite with the Algæ. One of the very commonest flagellate genera is Euglena. To the flagellates proper there have to be added the Choanoflagellata, with a single flagellum surrounded by a beautiful wine-glass-like collar—e.g. Salpingoeca, and the interesting Proterospongia—a colony with slight division of labour among its members and like a little fragment of sponge flesh; also the Dinoflagellata, with two flagella, one parallel, the other transverse to the long axis of the body—e.g. Peridinium, an extremely common marine form, affording food to some fishes; lastly, the Rhynchoflagellata, with a large locomotor flagellum, including two genera—the phosphorescent marine 'night-light' (Noctiluca), and Leptodiscus, a beautiful bell-like form, which seems within the compass of a single cell like a far-off prophecy of medusoid architecture.

Suctorio or **Acinetaria**.—Infusorians with cilia only in their free-living youth, usually fixed as adults, and always with prehensile or suctorial processes like tentacles, by means of which they prey upon other Protozoa. Acineta and Podophrya are suctorial; the common Acineta is only prehensile.

In beauty of form and movement, in the liveliness of their behaviour, and in the intricate phases

of their life-history. Infusorians afford almost inexhaustible material for investigation, which many workers have shown to be at once captivating in itself and full of biological suggestiveness. In the general economy of nature Infusoria are especially important as a food-supply to small animals, and in so far as they unite with Bacteria in working decaying matter once more into the cycle of life, or in reducing it to simpler elements.

See *PARAMECIUM*, *PROTOZOA*, *VORTICELLA*; Claparède and Lachmann, *Études sur les Infusoires* (Geneva, 1858-61); Stein, *Organismus der Infusions-Thiere* (Leip. 1859-83); Saville Kent, *Manual of the Infusoria* (Lond. 1880-82); Ray Lankester, article 'Protozoa,' *Encycl. Brit.* (1885); Maupas, *Archiv. Zool. Exper.* (vi. 1888); Bütschli, 'Protozoa,' in Bronn's *Thierreich*; Hartog in the *Cambridge Natural History* (i. 1906).

Infusorial Earth, *DIATOMACEOUS EARTH*, *KIESELGUHR*, a siliceous deposit formed chiefly of the frustules of Diatoms (q.v.). It is used as *Tripoli Powder* for polishing purposes, and as an absorbent of nitro-glycerine in making Dynamite (q.v.).

Inge, WILLIAM RALPH, was born in Yorkshire in 1860, and he had a brilliant career at Eton and Cambridge. He has held many positions as a lecturer and teacher where his work culminated on his appointment as professor of Divinity at Cambridge in 1907; and in the church by his preferment to the Deanery of St Paul's Cathedral in 1911. He is a thinker who, because he is unable to view the world with the undue optimism of the unthinking multitude, has been called a pessimist. He has published many works on subjects varying from *Eton Latin Grammar* (1889) to *The Philosophy of Plotinus* (1918), and *Personal Religion and the Life of Devotion* (1924).

Ingelheim, LOWER and UPPER, two small German towns, 10 miles E. of Bingen. The former claims to be the birthplace of Charlemagne, and has ruins of the magnificent palace he built here; the latter was once a free city of some importance.

Ingelow, JEAN (1820-97), a popular poetess and novelist, was born at Boston, Lincolnshire. A good deal of her poetry is of a devotional or religious cast, introspective in quality and melodious in style. But she also wrote some powerful ballads. Of her shorter pieces *The High-tide on the Coast of Lincolnshire, 1571*, is probably both the finest and the best known. Of her larger poems, *A Story of Doom* (1867) was the most successful. Among her novels may be mentioned *Off the Skelligs, Fated to be Free* (1875), *Don John* (1876), and *Sarah de Berenger* (1880).

Ingemann, BERNHARD SEVERIN, Danish poet and novelist, was born, 28th May 1789, at Thorkildstrup, in Falster. He first wrote lyrics (*Procne*, &c.), and then collections of *Fairy-tales and Stories*. But his best works were a series of historical novels, in which he took Walter Scott for his model—*Valdemar Seier* (1826), *Erik Menved's Childhood* (1828), *King Erik* (1833), and *Prince Otto of Denmark* (1835). The poems *Valdemar the Great and his Men* (1824), *Queen Margaret* (1836), and *Holger Danske* (1837), which are based, like his novels, on incidents of Danish national history and tradition, rank among Ingemann's most successful efforts. Besides being prolific he was also versatile, and essayed his hand in nearly all branches of pure literature, not the least estimable of his productions being *Psalms* (1825). From 1822 he taught Danish language and literature in the Royal Academy of Sorø, near Copenhagen. His collective works were published in 39 vols. (1843-64). He died 24th February 1862.

Ingermanland, or *INGRIA*, a province south of the Gulf of Finland, won by Peter the Great from Sweden, afterwards formed part of the government of St Petersburg.

Ingersoll, JARED, an American jurist, born in Connecticut in 1749, studied at Yale and in London and Paris, and became a prominent lawyer in Philadelphia. He was a member of congress in 1780-81, was in 1787 a delegate to the convention that framed the Federal constitution, and in 1812 was the Federalist candidate for the vice-presidency of the United States. He was a judge in the district court of Philadelphia at the time of his death, 31st October 1822.—His son, CHARLES JARED, born in Philadelphia, 3d October 1782, sat in congress in 1813-15, and there advocated the principle that 'free ships make free goods'; was for fourteen years United States district attorney for Pennsylvania; and was a prominent leader of the Democrats in congress from 1841 to 1847. He died 14th May 1862. He was the author of some poems and a drama, a political satire entitled *Inchiquin's Letters* (1810), and an *Historical Sketch of the War of 1812* (4 vols. 1845-52).

Ingersoll, ROBERT GREEN, was born at Dresden, New York, 11th August 1833, the son of a Congregational minister of very broad views. With his brother he opened a law-office at Shawneetown, Illinois, but removed in 1857 to Peoria. In 1862-65 he was colonel of a Federal cavalry regiment; in 1866 he was appointed state attorney-general. He was a successful lawyer, a well-known Republican campaign orator, and wielded considerable influence by his lectures, pamphlets, and books directed against the Christian religion. He died 21st July 1899. See a biographical appreciation by H. E. Kittredge (1911).

Ingleby, CLEMENT MANSFIELD, an eminent Shakespearian scholar, was born at Edghaston, Birmingham, 29th October 1823, was educated privately, and afterwards proceeded to Trinity College, Cambridge, where he graduated B.A. in 1847, and became M.A. in 1850, and LL.D. in 1859. He entered his father's office as a solicitor, and practised for a short time, though by no means assiduously or *con amore*; and after his father's death in 1859 relinquished the profession altogether to devote himself to a busy life of letters. He was one of the two English honorary members of the Weimar Shakespeare Society, an original trustee of Shakespeare's birthplace, a vice-president of the New Shakespeare Society (a post he afterwards resigned), and successively foreign correspondent and vice-president of the Royal Society of Literature. He died 26th September 1886.

His earliest work, *Outlines of Theoretical Logic* (1856), was followed by *An Introduction to Metaphysic* (1864-69) and *The Revival of Philosophy at Cambridge* (1870). But the most important work of his literary life began when he published *The Shakespeare Fabrications* (1859) and *A Complete View of the Shakespeare Controversy* (1861). These were followed by *Was Thomas Lodge an Actor?* (1868); *The Still Lion* (1874), enlarged into *Shakespeare Hermeneutics* (1875); *The Centurie of Praise* (1874); *Shakespeare: the Man and the Book* (1877-81); *Shakespeare's Bones* (1883); *Shakespeare and the Enclosure of Common Fields at Welcombe* (1885); and an edition of *Cymbeline* (1886). A selection of admirable *Essays* on a wide range of subjects was issued in 1888 by his son, Holcombe Ingleby, who prepared in the same year, for private circulation, a brief memoir of his father, with a collection of his epigrams, translations, and verses.

Ingoldsby, THOMAS. See *BARHAM*.

Ingolstadt (called *Aureatum* and *Chrysopolis*—i.e. 'the golden city'), a town of Bavaria, on the left bank of the Danube, 53 miles by rail N. of Munich. It contains two castles of the former dukes of Bavaria-Ingolstadt; the Gothic church of Our Lady (1425), in which is the tomb of Eck, Luther's opponent; and the former Jesuit college. Brewing, cannon-founding, and the manufacture

of gunpowder and salt are the only industries. Pop. (1885) 16,390; (1900) 22,206; (1919) 26,013, mostly Roman Catholics. A university was founded here in 1472, which reckoned Reuchlin and other eminent scholars among its professors, and a century after its foundation had 4000 students. It was removed to Landshut in 1800, and to Munich twenty-six years later. Ingolstadt was the first German town at which the Jesuits were permitted to establish themselves, and to teach publicly from the university chairs. Loyola gave it the fond title of 'his little Benjamin.' Here, too, Adam Weishaupt established the Illuminati (q.v.). Ingolstadt, which existed in the 9th century, was first fortified in 1539. In 1827 the fortifications, which had been destroyed by the French in 1800, were restored upon a first-class scale.

Ingres, JEAN DOMINIQUE AUGUSTE, French painter, was born at Montauban, 15th September 1781. He became a pupil of David in 1796, and five years later gained the 'Grand Prix.' In 1806 he proceeded to Rome, where he resided for fourteen years. He then spent four years in Florence, where he painted 'The Vow of Louis XIII,' a picture which, on being exhibited at the Paris Academy in 1824, broke down the indifference of the public to the work of Ingres. In 1819 he exhibited 'Paolo and Francesca di Rimini,' which showed clear traces of the Primitives, whom Ingres admired so much for the excellence of their drawing. In Italy he had adhered to the style of David, but had modified it by the inspiration he got from Raphael and other old masters. To this period belong some of his best portraits, and his 'Œdipus and the Sphinx,' 'Venus Anadyomene,' 'Romulus and Acon,' 'Virgil reading the *Æneid*,' 'Raphael and Fornarina,' 'Roger and Angelique.' Returning to Paris in 1826, Ingres was appointed professor of Fine Arts at the Academy, and became the recognised head of a great school. But the acrimonious criticisms passed upon his 'Apotheosis of Homer' (1827) and 'Martyrdom of St Symphorian' (1834) made him gladly embrace the opportunity of succeeding Horace Vernet as director of the French Academy in Rome in 1834. There he painted 'Stratonice' and the 'Portrait of Cherubini.' The exhibition of these and other pictures in Paris at length turned the tide of popular admiration full and strong in his favour. He relied more upon form and line than upon colour; some of his best productions, 'Girl after Bathing,' 'Œdipus and the Sphinx,' the 'Odalisque,' and the 'Fountain,' compositions of a few figures each, are unquestionably deserving of admiration. In 1854 appeared 'Joan of Arc at Reims,' which in its faultless drawing shows what the artist, who is reputed to have said that 'a thing well drawn is always well enough painted,' strove to attain. A picture, 'La Source,' perhaps the most beautiful of all his works, was shown in 1856, although it had been begun when he was a young man in 1824. This was succeeded by 'Le Bain Turc' (1864), painted when he was eighty-four. Ingres was essentially a draughtsman as David was a painter; in fact, he was one of the greatest draughtsmen who have ever lived. He died on the 14th January 1867. See Lives by Delaborde (1870), Blanc (1870), Schmarow (1884), Lapauze (1911), Manclair's *Great French Painters* (trans. 1904), Meier-Graefe's *Modern Art* (1908).

Ingrossing. See ENGROSSING.

Ingulph, abbot of Crowland, long considered the author of the *Historia Monasterii Croylandensis*, according to Ordericus Vitalis, was secretary to Duke William of Normandy, and was by him in 1086 made abbot of Crowland, where he died, 16th

November 1109. The *Historia Monasterii Croylandensis* was printed by Sir Henry Savile in his *Scriptores Rerum Anglicarum post Bedam* (1596), and in a more complete edition, with the continuation by Peter of Blois, in vol. i. of the *Rerum Anglicarum scriptores veteres* (Oxford, 1684). There is a translation by H. T. Riley in Bohn's Antiquarian Library (1854). Some writers even of the 18th century questioned the entire genuineness of the book. In 1826, in the *Quarterly Review*, Sir Francis Palgrave held that the whole so-called History was little better than a novel, and was probably the composition of a monk in the 13th or 14th century. Duffus Hardy sought to prove this. Riley held that the forgery of the charters began about 1393, and that the book was compiled about 1413 (in aid of a lawsuit with the town). Later writers have maintained that the book is not all a wanton forgery, though interpolated.

Inhambane, a port of Portuguese East Africa, lies just south of the tropic of Capricorn, and is beautifully situated, with good harbour and buildings. It exports maize, rubber, wines, and copal. Pop. 3000.

Inia (*Inia geoffrensis*), a toothed fresh-water Cetacean, not unlike a dolphin, but with certain anatomical peculiarities which keep it outside that family. It is found in some of the upper tributaries of the Amazons, and in the lakes near the Cordilleras. It measures about 8 feet in length, has a long cylindrical snout with stiff hairs, and a very slight dorsal fin. It feeds chiefly on fish, and is hunted for the sake of the oil which it yields.

Initials in mercantile documents will bind equally with the full signature; but the subscription to a bill of exchange by initials or marks will not warrant summary execution; and the pursuer of an action on the bill will have to prove that such initials or marks are the party's usual mode of subscribing.

Initiation, the admission of a person into a society, more especially the admission of youths, in the lower stages of civilisation, to full tribal rights. Traces of such ceremonies may be found in ancient and modern Europe; but the main areas are America, Australia, and Africa, with marked differences in detail.

In North America the initiation fast is commonly the prelude to membership of a cult-society; among the Omaha a youth seeks a secluded spot in the hills and must fast till he falls asleep or into a trance. Whatever appears to him in a vision will be his protector in life, and he carries with him a small portion of any bird or beast so seen; it is the most sacred thing he possesses.

In South America there are initiation rites for girls as well as boys among some tribes. In the case of the latter a marked feature of the rites in some areas was the flogging of the boys or other painful tests of manhood.

Australian initiation rites are of several different types. In the south of Victoria, linguistically the oldest area, are found the simplest ceremonies; in them no mutilations or deformations of any sort are practised. Then come tribes in which two or more teeth are knocked out. Beyond these, the central feature of the ritual is circumcision, with or without the knocking out of teeth, the ceremonies being at times in several stages, celebrated at intervals. Beyond these tribes, again, circumcision is accompanied by subincision, a rite found also in Fiji. In all, or nearly all, cases the painful operations are accompanied by instructions in the moral code of the tribe and the revelation of tribal mysteries, such as the bull-roarer.

African rites are equally varied, but their distribution is less regular. There are large areas in

which circumcision is not known; it probably found its way into Africa by more than one route. Tooth deformation and evulsion varies in its distribution independently of circumcision, and may or may not be combined with it. Some tribes (West Africa, Equatorial zone) point the incisors, upper, lower, or both; some (Angola) simply round the middle incisors at the bottom; Nilotic peoples, the Ovambo, &c., knock out the lower incisors, while the Zambesi tribes remove the upper. Some of the tribes, e.g. Baya, have rites that recall the trials of the Australian candidate. The candidates are dropped into a river, wounded with a spear, &c., and we are on the border-line of Secret Societies (q.v.). The Masai have a series of age-grades, through which all must pass; but the rites consist only of a few days' seclusion. Among the Ibo, membership of the 'grades' is not compulsory; but no one was of much account unless he reached one of the higher ranks; money payments, divided among the members, were the essential element in the progress from grade to grade.

The literature of the subject is scattered in works dealing with the areas mentioned; there is no general discussion of the subject.

Initiative and Referendum are political institutions under which the people of a nation or state may initiate measures to be enacted by their own votes into laws, and may demand that laws enacted by a legislative body shall be referred back to the people for approval or rejection. In this way the body of the people are given a direct voice in the making of their laws. The system here indicated was first adopted in Switzerland (q.v.). It has been introduced into the United States, and now exists as a constitutional provision in a number of the states, South Dakota (1898), Oregon (1902), and several others since these dates. The working of the system in Oregon has attracted much attention, and has proved so satisfactory as to give it a growing popularity. Of the new states, Oklahoma and New Mexico have made the initiative and referendum a provision of their constitutions, and Arizona has added to these a provision for the Recall, the latter giving the people the right to 'recall' or dismiss from office by a popular vote officials who have proved unsatisfactory. The recall has been adopted by many cities, first by Los Angeles, California, in 1903, and has been put in effect against the mayors of Los Angeles and Seattle and other officials elsewhere.

Injections. See CLYSTER, HYPODERMIC INJECTIONS, TRANSFUSION OF BLOOD.

Injector. Fig. 1 shows in section a simple form of injector for raising water. Steam issuing from the pipe S, into the vessel WR, will first create a partial vacuum above W by dragging air with it, and then, when the water-level is above the nozzle, will, on collapsing by condensation, impart its energy to the water and drive it up through the narrow neck below R, to a height of about one foot for every pound of steam-pressure per square inch. It is doubtful whether these injectors can work so economically, as regards expenditure of steam, as ordinary slow-moving pumps do; but they possess many conveniences and advantages which are bringing them into use.

Feed-pumps, for feeding water into steam-boilers, are difficult to keep in order when driven at high speed. The very rapid action

of the valves severely tries their durability. In the case of locomotives inconvenience was often occasioned by the fact that their feed-pumps acted only when they were running; and thus, if an engine happened to stand still for any length of time, the water occasionally got too low in the boiler. M. Henri Giffard's injector, now in general use in place of high-speed feed-pumps, acts equally well whether the engine is running or at rest.

The diagram fig. 2 will give an idea of the essential parts of Giffard's injector. A is the steam-boiler, B the water-level, CDF a pipe into which steam is admitted: this pipe terminates in a cone DF, which is enclosed in a larger cone HH. In the cone DF the pointed plug E can be raised or lowered so as to increase or diminish the area of the aperture at its lower end F. G is a pipe communicating with the water-cistern, and admitting water into the external cone HH. K is a pipe communicating with the boiler under the water-level. On opening communications between the boiler and this apparatus it might be expected that steam would rush out at F, and water at K, both currents meeting with great force, and escaping into the atmosphere between the two openings.

Paradoxical as it may appear, the water at K, although it is actually, by reason of the head of water arising from the difference of level between the aperture at K and the water-level at B, subject to a greater boiler-pressure than is the steam in the cone DF, is yet overpowered, and driven back into the boiler by the stream of water and condensed steam issuing from H; and thus water, from the

Fig. 2.

tender or cistern, is introduced into the boiler, and constitutes the feed-water. The energy of the collapsing steam at F is transferred to water in HH; this is driven forward in a stream, which is at its narrowest at K; in this stream the actual energy per unit of bulk at K thus comes to exceed the potential energy of the boiler-water at K, and its actual velocity to exceed the possible velocity of outflow from K; whence the outflow from K is overpowered. In practice this injector is a somewhat expensive apparatus in consequence of the number of adjustable parts required. Variations in the pressure of steam require alterations in the area of the steam-passage, and in the distances between the mouths of the conical openings for the outflow and inflow of steam and water.

Injunction, in English law, is an introductory writ, by which a superior court stops or prevents some inequitable or illegal act being done. If the party disobeys the injunction he may be attached for contempt of court, and imprisoned till he obeys. In Scotland a remedy of a similar kind is called an Interdict (q.v.).

Ink is a general term for any fluid substance which, when applied to a suitable surface, leaves upon it a partially or wholly indelible impression. Any such fluid may be used for writing purposes; but, as the recording material is generally paper, this fluid must have either an affinity for the fibrous matter of which the paper is made, or for the sizing material used to produce upon it a homogeneous surface. This is necessary to prevent the removal of the ink by water; and this power of mordanting itself is one of special importance, as upon it depend the permanency and indelibility of the records. Certain salts have this property, especially salts of iron, which when exposed to the air absorb oxygen, the result of which is that the pale blue-green solution produced by mixing protosalts of iron with vegetable matters containing tannic or gallic acid is converted into a dense blue-black insoluble compound, which cannot be removed from the paper unless it is tampered with by means of chemicals capable of decomposing or destroying it. It is owing to the formation of this insoluble compound that writing-ink, when left in open vessels exposed to the air, becomes thick and ropy, and unfit for use. These inks are known to have been used as early as 900 A.D. Other black inks are prepared from salts of chromium and vanadium. These inks are in some cases more suitable than the simple writing-inks described above. Sulphate of indigo is also used as a colouring matter, and was introduced by Stephens in 1836. A black ink which lays claim to indelibility is prepared from nigrosine, one of the aniline compounds; but the colour is much inferior to that of ordinary inks, and is not absorbed by the paper fibre to the same extent. Writing-inks are generally acid in character, which causes the corrosion on metal pens; but this property rather tends to enhance the value of the ink, as it retards the bleaching action noticeable in old documents. Creasote, or common wood vinegar, is added to most inks to prevent moulding.

The following will be found excellent recipes for the manufacture of black writing-ink on a small scale: '*With galls and sulphate of iron.*—1 lb. bruised galls, 1 gal. boiling water, $5\frac{1}{2}$ oz. of sulphate of iron (copperas) in solution, 3 oz. gum-arabic, previously dissolved, and a few drops of an antiseptic, such as carbolic acid. Macerate the galls for twenty-four hours, strain the infusion, and add the other ingredients. *With Logwood.*—Boil 10 oz. logwood in 20 oz. of water; boil again in 20 oz. more water, and mix the two decoctions; add 2 oz. chrome alum, and boil again for quarter of an hour; and 1 oz. gum-arabic. The product is 25 oz. deep black ink.'

Copying-inks are prepared by adding sugar, gum, or glycerine to ordinary writing-inks. These substances protect the colouring matter (combined with the iron) from the oxidising influences of the air, by forming a skin or impervious varnish over the writing. Thus, when the damp 'tissue' is pressed upon the writing, sufficient unoxidised ink is transferred to stain the paper from back to front, and expose a legible copy on the upper side. Aniline colours dissolved in water holding gum or sugar in solution are also used as copying fluids. Owing to their intense colouring power these inks are useful where many copies from one document are required, but only for temporary use, as on exposure to air or light these colours quickly fade, and the record is lost. Copyable printing-ink is prepared from these materials; and, when written and printed matter is to be copied, as on way-bills or invoices, its use is a great convenience. Copyable pencils are prepared from the same materials (in a solid form). But there is a very serious objection to the use of such inks and pencils:

the printed or written matter can be entirely removed by means of alcohol or other solvents.

Many attempts have been made to produce writing-inks which would hinder or render impossible tampering with documents, but without much success. The necessity for such inks seems exaggerated, as it has been found that even with the best manipulative skill and chemical knowledge it is practically impossible wholly to remove writing produced with the common iron and tannin ink, such as is almost universally used.

Coloured Inks.—These are essentially solutions of colouring matters. Red ink is best prepared by dissolving pure carmine in ammonia; blue, by dissolving Prussian blue in oxalic acid; green, by dissolving one per cent. methyl green in warm water. Other colours can also be simply prepared, but not being in demand are not usually met with in commerce. The desirable properties in all writing-inks are that they shall flow freely and not gum or clog the pen, that they shall remain perfectly fluid (without depositing the colouring matter), and that they shall be reasonably permanent in character.

Sympathetic Inks.—These are of great variety, and although possessing an interest to the lover of the marvellous, are not in common use. Salts of lead or bismuth, on being treated with sulphuretted hydrogen, give a black impression. When a weak solution of galls or tannic acid is used the paper on being plunged into a bath of a per-salt of iron will show the characters in black. This is a useful method of restoring faded old writing, and in cases where chemicals have been used with the purpose of removing it. See also COBALT.

Printing-ink.—This is a greasy or oily compound in which solid pigments are held in suspension, and is altogether different both in appearance and composition from the writing-inks we have described. It also is usually applied to paper surfaces, and amongst other qualities it must possess the property known to printers as 'distribution'—i.e. of being easily spread out in a layer, the tenuity of which will not cause it to fill up the interstices of and between the types; it must also attach itself to the paper when the type is pressed upon it, detaching itself from the latter entirely; it must possess the apparently opposite properties of drying on the paper within reasonable time, whilst it shall not do so on the type, rollers, or ink-tables during the operation, and, lastly, it should be permanent in so far as the impressions on paper should have no tendency to change in colour or for the outlines of the type to become blurred. The various qualities of printing-ink may be described under three heads, viz. (1) newspaper inks, (2) bookwork inks, and (3) lithographic inks. With the common and consequently cheap printing-inks it is not necessary that the more expensive drying oils be employed as a vehicle or varnish for the colouring matter. Common oils made from paraffin and resin are used, mixed with ordinary lampblack. From this compound, when applied to the surface of printing-paper, the oily matter is absorbed, leaving the colouring matter as a stain on the outside, which does not 'set off' immediately after printing to such an extent as to prevent its employment for cheap periodicals and newspapers. The better class of printing-inks, however, especially in illustrated work, must actually dry upon the surface of the paper in the same manner as paint will dry when applied to a wall. This result is obtained by the employment of drying oils—that is, oils which have the property of absorbing oxygen by the process of boiling and becoming gum-like or resinous in character. Thus, when the ink, prepared from linseed, poppy, or walnut oil, is exposed to the atmosphere, especially if assisted by heat, the colouring matter becomes imprisoned or varnished over with a resin-

ous coating, which prevents it setting off or staining any substance brought in contact with it. In preparing the varnish of such inks the oils already mentioned are heated to 500° or 600° F., at which temperature they are kept for a period varying with the degree of viscosity or thickness of the varnish required. In this operation the oil (a compound of fatty acids with glycerine) gradually thickens, without much loss of colour or weight, pungent fumes of acrolin, due to the decomposition of the glycerine, being given off. The varnish so produced is mixed with lampblack, prepared either from coal or burning oil, or from the imperfect combustion of gas, and after very careful grinding is in a condition for use.

The manufacture of coloured inks is practically much the same as for black inks, only great care must be exercised to secure the purity of the varnish, and to see that the chemicals employed do not react upon one another. For example, when vermilion (which is a compound of sulphur and mercury) is employed with colours containing iron or lead, the splendid colour of the vermilion is entirely destroyed by the formation of black sulphur compounds with the iron and lead. It is impossible in such an article to give more than the general outline of this manufacture, with which are connected many mysterious processes for which there is no obvious chemical explanation. The chief drawback in regard to coloured printing-inks is their tendency to fade on exposure to the air and light. This drawback has become more accentuated since the introduction of coal-tar colours, with which it seems to be the rule that the more brilliant and beautiful are they the less they are fit to resist these destructive influences.

In lithography both writing and printing inks are employed, these being of a peculiar character. The former consists of a soapy fluid holding in suspension fatty matters (shellac, white wax, and tallow), which on being transferred to the stone are absorbed and retained by its porosity. The subsequent application of lithographic printing-ink (which is only the finest variety of printing-ink prepared in an especial manner) to the damp surface of the stone causes it to collect and form a layer on the portions which the lithographic writing-ink has penetrated. As in the case of letterpress-inks, those for lithographic purposes are prepared in black and coloured varieties.

Special inks are prepared for collotype and tinplate printing. Stamping or obliterating inks may either be prepared by thinning down black or coloured letterpress printing-inks with linseed-oil or turpentine, or by grinding aniline colours with glycerine and treacle.

Indian Ink or China Ink.—This is a mechanical mixture of the purest and densest lampblack, with a solution of gum, gelatine, or of agar-agar, the use of which may be traced as far back as 2697 B.C., with a solution of gum, gelatine, or of agar-agar. The black paste is dried and pressed so as to form cakes, in which condition it is sold. The lampblack is prepared by burning sesame or other oil, controlling the supply of air so that in place of a clear flame the carbon from the burning oil is deposited in fine flakes in the form of lampblack. For the very finest varieties the material used for this purpose is camphor. The lampblack or carbon so produced is amorphous, and of an intensely black colour. In this condition it is seldom used for the purpose of ordinary writing, but when rubbed down with water forms a material used by draughtsmen for plans, &c. Inks of a similar nature can be prepared by mixing the solutions already mentioned with colouring matter.

Marking-ink.—When certain salts of silver or platinum are applied to textile fabrics these

materials are reduced in the fibres of the fabric, and the writing so produced is not removed by the ordinary scouring process to which such articles are subjected. Aniline in the presence of oxidised substances also produces a useful indelible ink.

Ink-stains.—The removal of writing-ink stains from linen is easily effected, by alternately dipping the parts in a solution of oxalic acid and hypochlorite of lime (or soda). If the stains be old and have assumed the brown colour of iron mould, warm diluted hydrochloric acid will be found effectual in their removal. When the fabric is coloured the removal of ink-stains is more difficult, as the chemicals employed in the former case are inadmissible. In this case a solution of pyrophosphate of soda may be used with advantage, as this salt does not seriously affect even delicate colours. It is of course necessary thoroughly to wash the fabric after the removal of the stains.

Inkermann, a village in the Crimea, situated near the eastern extremity of the harbour of Sebastopol. See CRIMEAN WAR.

Inland Revenue. See EXCISE, TAXATION.

Inlaying is the art of decorating flat surfaces by the insertion of materials differing from the ground or body in which they are put, in colour, texture, or other qualities. The body or basis may be wood, stone, or metal, and the inlaid or encrusted substances may be woods of various colours, ivory, mother-of-pearl, tortoiseshell, precious and other metals, marbles, and hard and precious stones, all these substances being selected principally on account of the brilliance and variety of their colours. Inlaying in wood is known generally as *marquetry*; in metals the inlay principally practised is called *Damascening* (q.v.); and in marble and precious stones it forms a variety of *Mosaic-work* (see MOSAICS). As of most decorative arts, the origin of inlaying can be traced to eastern countries. While some kinds of inlays were known in ancient Egypt and Rome, the art as practised in modern times first took root in Venice in the 15th century, when small caskets were ornamented with inlays of ivory and wood in strictly geometrical patterns, such as continue to be reproduced to this day in the familiar inlaid-work of Bombay. Contemporaneously the Florentines began to ornament furniture, &c. with small inlaid dice of ivory arranged to form various patterns, and this style of inlay has since become generally known as *Certosa-work*, from the fact that the choir-fittings in the church of the Certosa or great Carthusian monastery, near Milan, are ornamented in this manner. From these beginnings developed the *Tarsia-work* of Italy of a century later, which, dealing at first with geometrical patterns in wood, developed into inlaid representations of architecture, views, figures, and drapery, and finally into foliaceous scrolls of modern marquetry. Marquetry-work in furniture was greatly elaborated in France, Germany, and Holland towards the close of the 17th century, and workers in wood found great delight in skilful elaboration of intricate designs. Towards the close of the 17th century a new development of marquetry was effected by a French artist, Charles André Boulle, in the exclusive use of inlaid veneers of tortoiseshell and brass, now known as *Buhl-work*. Both in design and execution Boulle's work was of remarkable excellence. The marquetry work of France and Italy is of the finest quality, followed by Dutch and Flemish (where satin, tulip, sycamore, and holly were used for inlaying). Introduced into England by William III., by the time of Queen Anne it had developed into a much more delicate and elaborate class of work than the original.

Pietra-dura, which consists of an inlay of bright-coloured, hard, and precious stones, in slabs of marble or in panels of wood, is allied to the ancient mosaic-work which flourished in the palmy days of Rome; but true mosaic, although embedded, is not inlaid. *Pietra-dura* began to be made in Italy in the 15th century, but its extreme costliness prevented its extensive application. Two varieties were made in Italy, one being an inlay of minute pieces of stones with colours so arranged as to form a design or picture, like mosaics of larger size. This is known as Roman mosaic, in contradistinction to Florentine mosaic, which consists of slices of stone shaped and inserted to form definite portions of the required design. This latter class of inlaid-work was introduced into India by a French artist, Austin de Bordeaux, who decorated the famous Taj Mahal at Agra in *pietra-dura* of the richest and most elaborate character. The art then took root in that region, and to this day *pietra-dura* of manifestly European character in design continues to be a characteristic art industry of Agra.

The ornamental treatment of metals by inlaying is principally confined to the inlaid-work and inlaying of wire and fine plates of gold and silver into iron, steel, and bronze. The inlaying of gold and, to a minor degree, silver wire into iron or steel is known as Damascening (q.v.). In India such damascening is known as Kufi-work, and is extensively practised in the United Provinces. Effective combinations of inferior metals are also made in India; silver inlaid in a black alloy of copper, lead, and tin being known as Bidri-work, from Bidar, in the Deccan. Combinations of copper and brass, and of brass and tin, are also common in the household vessels of the Hindus. The Japanese, who possess many alloys, excel in combining and inlaying them, often in relief, in their art metal manufactures.

Inn (ancient *Ennis*), a river of Germany, the most important Alpine affluent of the Danube, rises in the south of the Swiss canton of Grisons, and flows north-east through the valley of the Engadine, and onwards through Tyrol and Bavaria, to its junction with the Danube at Passau in a stream (320 yards) broader than that of the Danube. Its total course is 317 miles. In Bavaria its bed is broad and sown with islands.

Inn is the legal designation of a house or hotel where lodging and refreshment are provided for travellers generally. Public-houses, &c. are not properly described as inns unless some rooms are set apart for guests to lodge in. An inn may be set up without a license; but if excisable liquors are sold the innkeeper must take out a license; and even temperance hotels are made subject to police inspection, to prevent evasion of the law.

An innkeeper is bound to open his house to travellers generally; he may not refuse refreshment or lodging to any person who is able and willing to pay, unless such person is drunk or disorderly, or tainted with infectious disease. He is, of course, bound only to give such accommodation as he has. If the traveller has a horse and luggage the innkeeper is bound to receive them if he has accommodation, provided the traveller himself intends to lodge there as a guest. But the traveller is not entitled to select whatever room he pleases, and if he will not accept such reasonable accommodation as is offered, the innkeeper may order him to leave the house. An innkeeper has a lien or right to detain the horse, carriage, or goods of his guest for that part of the reckoning applicable to each respectively, and this lien he acquires even if the horse, &c. be not the property of the guest. - He has no right to detain the person of his guest.

By the Roman law an innkeeper was bound to restore goods entrusted to him by his guests, unless they were lost by some *damnum fatale*, or inevitable misfortune; this was the effect of a clause in the edict beginning *Nauta, caupo, stabularii*. The same rule was adopted by the English common law. Hence, if a guest was robbed of his goods at an inn the innkeeper was liable, unless the guest had taken upon himself the care of his own property, or the loss was due to the default or negligence of the guest himself, his servant, or companion: and the landlord was not permitted to escape liability by putting up a notice that he would not be answerable for losses. But the Innkeepers Act, 1863, provides that an innkeeper shall not be liable to make good the loss of any goods, &c. (not being a horse or carriage) to a greater amount than £30, unless the loss has been occasioned by his own wilful default, or the property has been deposited with him for safe custody. A copy of the first section of the act must be exhibited in the hall or entrance to the inn. The liability of innkeepers in respect of goods belonging to their guests extends to all keepers of public-houses, &c., but not to persons who let lodgings. The keeper of a boarding-house or lodging-house is free from liability if he exercises ordinary care—i.e. such care as he takes of his own goods. The Innkeepers Act of 1878 permits a landlord (after giving notice as required by the act) to sell the property of a guest who has left without paying. In Scotland the Roman rule of law as to innkeepers' liability has been adopted, and the law is substantially the same as in England, except that no indictment would lie against an innkeeper for refusing a guest. See further, as to the licenses required by innkeepers, the articles LICENSING LAWS and LIQUOR LAWS.

Innate Ideas. See COMMON SENSE, DESCARTES, LOCKE.

Inner House, the name given in Scotland to the higher divisions of the Court of Session (q.v.).

Innerleithen, a police-burgh (1869) of Peebles-shire, near the Tweed's left bank, 6 miles ESE. of Peebles, and 12 W. of Galashiels. Its first woollen-factory was established in 1788, about which time its saline spring (Scott's 'St Ronan's Well') came into celebrity; but the great extension of its woollen industry dates from fifty years later. Pop. 2400.

Inner Temple, one of the Inns of Court (q.v.).

Innes, COSMO, lawyer, antiquary, and historian, was born at Durris, on Deeside, 9th September 1798. His father, formerly the laird of Leuchars, was a scion of the old family of Innes of Innes. Cosmo was educated at the Edinburgh High School, and he graduated both at Glasgow and Oxford. In 1822 he passed as a Scottish advocate, became sheriff of Moray in 1840, and subsequently was appointed clerk to the Second Division of the Court of Session. In 1846 he was elected to the (unpaid) chair of History in the university of Edinburgh. Cosmo Innes is perhaps best known as the author of *Scotland in the Middle Ages* (1860), and *Sketches of Early Scotch History* (1861), but he also prepared the first volume of *Acts of the Scottish Parliament*, and at the time of his death was engaged on an index to the whole series. He was further a most industrious member of the Bannatyne, Maitland, and Spalding Clubs, and edited for them several of the register-books of the old religious houses of Scotland, with other historical documents of great importance. He published a volume of lectures on *Legal Antiquities* (1872), and was the author of several memoirs, including one of Dean Ramsay. Cosmo Innes died suddenly at Killin, 31st July

1874, in his seventy-sixth year. See the Memoir by his daughter, Mrs Hill Burton (1874).

Innes, THOMAS, a Scottish historian, known better as 'Father Innes,' was born in 1662 at Drumgask, on Deeside, Aberdeenshire. At fifteen he was sent to Paris, where he studied at the College of Navarre and the Scots College, of which latter body his eldest brother Lewis (1651-1738) was principal from 1682. Thomas received priest's orders in 1692, and after three years of mission work at Inveraven, Banffshire (1698-1701), returned to Paris, and became prefect of studies in the Scots College, where he died, 28th January 1744. To pursue his researches he had paid a visit or two to England and Scotland; and Wodrow, who saw him at Edinburgh in 1724, describes him as 'a monkish, bookish person, who meddles with nothing but literature.' Withal he was a staunch Jacobite, but no Ultramontane; not free, indeed, from suspicion of Jansenism. He may justly be looked on as the precursor of Niebuhr and Niebuhr's successors; for his *Critical Essay on the Ancient Inhabitants of Scotland* (2 vols. 1729) is much the earliest of all scientific histories. It was meant for an introduction to a *Civil and Ecclesiastical History of Scotland*, one volume of which, coming down to Columba's death, he prepared for the press, whilst another, bringing down the narrative to 831, was left incomplete. Both were edited for the Spalding Club by Dr Grub in 1853. The aim of the whole work was 'to counteract the inventions of former historians [Hector Boece], and to go to the bottom of the dark contrivances of factious men [George Buchanan] against the sovereignty of our kings;' and, though he thus wrote with a purpose, his honesty and acumen were such that the work retains a permanent value. See the Memoir by Dr Grub prefixed to the reprint of the *Critical Essay* ('Historians of Scotland' series, vol. viii. 1879).

Innocent, the name of thirteen popes, the most remarkable of whom are the following.—**INNOCENT I.**, a native of Albano, was elected Bishop of Rome in 402. Next to the pontificate of Leo the Great that of Innocent forms the most important epoch in the history of the relations of the see of Rome with the other churches, both of the East and of the West. He was earnest and vigorous in enforcing the celibacy of the clergy. He maintained with a firm hand the right of the Bishop of Rome to receive and to judge appeals from other churches, and his letters abound with assertions of universal jurisdiction, to which Catholics appeal as early evidence of the Roman primacy. Innocent I. died in 417, and was canonised.—For Innocent II. see **POPE**, **ANTIPOPE**.

INNOCENT III. (**LOTHARIO CONTI**), by far the greatest pope of this name, was born at Anagni in 1161. After a course of much distinction at Paris, Bologna, and Rome, he was made cardinal; and eventually in 1198 was elected, at the unprecedentedly early age of thirty-seven, a successor of Pope Celestine III. His pontificate is justly regarded as the culminating point of the temporal as well as the spiritual supremacy of the Roman see; under the impulse of his ardent but disinterested zeal for the glory of the church, almost every state and kingdom was brought into subjection. In Italy, during the minority of Frederick II., who was a ward of Innocent's, the authority of the pope within his own states was fully consolidated, and his influence among the other states of Italy was confirmed and extended. In Germany he adjudicated with authority upon the rival claims of Otto the Guelph and Philip of Swabia; in France he compelled Philip Augustus to dismiss Agnes de Meranie, whom he had unlawfully married, and to take back Ingeburga. In Spain he exercised

a similar authority over the king of Leon. The history of his conflict with and triumph over John of England displays in a stronger light the extent of his pretensions and the completeness of his supremacy. Even the king of Armenia, Leo, received his legates. And, as if in order that nothing might be wanting to the completeness of his authority throughout the then known world, the Latin conquest of Constantinople and the establishment of the Latin kingdom of Jerusalem put an end, at least during his pontificate, to the shadowy pretensions of the eastern rivals of his power, spiritual as well as temporal. His views of the absoluteness of the authority of the church within her own dominion were no less unbending than his notion of the universality of its extent. To him every offence against religion was a crime against society, and in his ideal Christian republic every heresy was a rebellion which it was the duty of the rulers to resist and repress. It was at his call, therefore, that the crusade against the Albigenses was organised and undertaken. As an ecclesiastical administrator Innocent holds a high place in his order. He was a vigorous guardian of public and private morality, a steady protector of the weak, zealous in the repression of simony and other abuses of the time. He prohibited the arbitrary multiplication of religious orders by private authority, but he lent all the force of his power and influence to the remarkable spiritual movement in which the two great orders, the Franciscan and the Dominican, had their origin. It was under him that the celebrated fourth Lateran Council was held in 1215. In the following year he was seized with his fatal illness, and died in July at Perugia at the early age of fifty-six. His works embrace sermons, a remarkable treatise on the *Misery of the Condition of Man*, and a large number of letters. The 'golden sequence' 'Veni, sancte Spiritus' has been attributed to him by some. It is from his letters and his decretals alone that the character of the age and the true significance of the church policy of this extraordinary man can be fully understood. However earnestly men may dissent from these views, no student of mediæval history will refuse to accept Dean Milman's verdict on the career of Innocent III. that 'his high and blameless, and, in some respects, wise and gentle character, seems to approach more nearly than any one of the whole succession of Roman bishops to the ideal light of a supreme pontiff;' and that 'in him, if ever, may seem to be realised the churchman's highest conception of a vicar of Christ.'

See Milman's *Latin Christianity*, vol. v.; Jorjy's *Innocent III.* (1853); works in German by Hurter, Deutsch, Schwemer, and Brischar; Pirie-Gordon's *Innocent the Great* (1907); and a great work by Luchaire (6 vols. 1903-8).

INNOCENT XI. (**BENEDETTO ODESCALCHI**), born at Como in 1611 and elected in 1676, was one of the most distinguished among the popes of the 17th century. He was a vigorous and judicious reformer; but his historical celebrity is mainly owing to his contest with Louis XIV. The dispute began with an attempt on the part of the pope to put an end to the abuse of the king's keeping sees vacant, in virtue of what was called the *Droit de Regale*, and appropriating their revenues. The resistance to this attempt drew forth the celebrated declarations of the French clergy as to the Gallican Liberties. But the actual conflict regarded the immunities enjoyed by the foreign ambassadors residing in Rome, and especially the right of asylum, which they claimed not only for their own residences, but also for the adjoining district. These districts had gradually become so many nests of crime, and of frauds upon the revenue; and the pope gave notice

that he would not thereafter receive the credentials of any new ambassador who should not renounce these abusive claims. The great powers murmured at this threat, but it was with France that the crisis occurred. Louis XIV. instructed his new ambassador to maintain the dignity of France, and sent a large body of military and naval officers to support his pretensions. Innocent persisted in refusing to grant an audience to the ambassador. Louis, in reprisal, seized on the papal territory of Avignon; but the pope was immovable, and the dispute was not adjusted till the following pontificate. Innocent died in 1689. The pope of Brownings's *Ring and the Book* was Innocent XII. (Pignatelli), pope in 1691-1700.

Innocents, HOLY. See CHILDREMAS.

Innominate Artery (*Arteria innominata*) is the first large branch given off from the arch of the Aorta (q.v.).

Innominate Bone. See PELVIS.

Innsbruck, the capital of Tyrol, 109 miles by rail S. of Munich, stands on the Inn at its junction with the Sill, 1880 feet above sea-level, surrounded and overhung by mountains ranging from 7500 to 8500 feet high. It is a beautiful place, with broad tree-shaded streets, arcaded shops, and four squares adorned with statues. The Franciscan church, or Hofkirche, built in the Renaissance style in 1553-63, contains a beautiful and elaborate monument to the Emperor Maximilian I. (who, however, is buried in Vienna). It consists of a marble sarcophagus supporting the emperor's effigy in bronze, in a kneeling posture; while on both sides of the aisle are twenty-eight bronze figures of royal (mostly Hapsburg) personages, by Peter Vischer and other German artists. In the same church are monuments to Andreas Hofer and his comrades Speckbacher and Haspinger, and to the Tyrolese who fell in the wars against France (1796-1809). The parish church of St James has a picture of the Virgin by Lucas Cranach. The other chief buildings are the imperial castle, built by Maximilian I. and restored by Maria Theresa in 1766-70; the 'Golden Roof Palace'; the national museum, the Ferdinandeum; and the university (founded in 1677, and, after several vicissitudes, organised anew in 1826). To the university are attached a library, a botanical garden especially rich in Alpine plants, and the usual museums, laboratories, &c. Amongst the many monasteries of Innsbruck is the first that the Capuchins founded in Germany (1594). A colossal statue of Andreas Hofer was unveiled in 1893. Innsbruck carries on manufactures of woollen cloth, machines, and glass and glass-painting. It is much visited in summer by tourists. Pop. (1890) 23,320; (1900) 26,866; (1910) 53,194; (1923) 56,365—almost all Catholics. Innsbruck has always been a place of some commercial importance, owing to its situation at the ford across the Inn and at the head of the Brenner Pass to Italy. The Romans had here their principal colony in Rætia. From 1180 the town belonged to the Counts of Meran; in 1363 it passed with Tyrol to Austria. The stormiest period of its history fell in the days of Hofer (q.v.).

Inns of Court, the name given to certain voluntary societies which have the exclusive right of calling persons to the English bar. These societies had their origin in the 13th century, when the clergy ceased to practise in the law-courts, and their place was taken by lay professors, 'apprentices,' and students of law who congregated in the neighbourhood of Westminster. There are four Inns of Court—Lincoln's Inn, the Inner Temple, the Middle Temple, and Gray's Inn. Each possesses a dining-hall, library, and chapel, the Temple Church being used as a chapel by both the societies

which take their name from the buildings which once belonged to the Knights Templars. Each inn derives a considerable income from houses and chambers occupied by barristers and others, and each is governed by an irresponsible body called the Benchers. New members of this body, who are usually judges or senior counsel, are chosen by the existing members. The inns possess equal privileges; since 1855, when a royal commission reported on their revenues and constitution, they have joined in providing lectures for the benefit of students, and in examining candidates for admission to the bar. They have discretion to admit or refuse any candidate without assigning their reasons; but no objection is made to the admission of any person of good character. Each inn exercises discipline over its own members, and has power to disbar them—i.e. to withdraw from them the right to practise; but there is an appeal to the judges from the decision of the benchers. The right of disbarring is exercised only in the case of persons guilty of criminal offences or gross professional misconduct; a formal inquiry is held, but the results of the investigation are not made public. Serjeants' Inn was formerly a society composed of barristers and judges belonging to the 'order of the coif,' but this inn was abolished in 1877. The smaller societies, sometimes called Inns of Chancery, have never been of any great importance; their buildings have passed into the possession of one or other of the inns of court, or have become the property of small private societies of solicitors, &c. Staple Inn and Clement's Inn are interesting by reason of the collegiate character of their buildings. For further information, see the Report of the Commission of 1855. The steward of any of the inns of court will furnish intending candidates for the bar with information as to the terms of admission. See BARRISTER; Pearce's *Inns of Court* (1848); Bellot's *Inner and Middle Temple* (1902). The society known as the King's Inns in Dublin performs the duties of an inn of court in relation to the Irish bar. The Scottish bar is organised on an entirely different plan (see ADVOCATE).

Innuendo, a part of a pleading in cases of libel and slander, pointing out what and who was meant by the libellous matter or description.

Inoculation ('engrafting'), the communication of disease to a healthy subject by the introduction of a specific germ or animal poison into his system by puncture or otherwise, originally used of the inoculation of smallpox (for preventive inoculation, see BACTERIA, GERM, ANTHRAX, DIPHTHERIA, HYDROPHOBIA). If the matter of a smallpox pustule, taken after the commencement of the eighth day, be inserted in or beneath the skin of a person who has not previously suffered from smallpox, the following phenomena are induced: (1) Local inflammation is set up; (2) on the seventh or eighth day there is fever similar to that of smallpox; and (3) after the lapse of three more days there is a more or less abundant eruption of pustules. This process is termed inoculation, and the disease thus produced is denominated inoculated smallpox. The disease produced in this artificial manner is much simpler and less dangerous than ordinary smallpox; and as it was an almost certain means of preventing a subsequent attack of the ordinary disease, inoculation was much practised till it was superseded in the beginning of last century by Jenner's introduction of vaccination. The importance of inoculation was recognised in the East at a very early period, the Chinese practising it from the 6th century, and the Brahmins from a very remote antiquity. In Persia, Armenia, and Georgia it was in use, and it is even said to have been employed in Scotland

and Wales. It was not, however, till Lady Mary Wortley Montagu wrote her celebrated letter from Adrianople in 1717 that the operation became generally known in England. In that letter she writes: 'The smallpox, so fatal and so general amongst us, is here entirely harmless, by the invention of *in grafting*, which is the term they give it. Every year thousands undergo the operation. There is no example of any one that has died in it, and you may believe that I am very well satisfied of the safety of the experiment, since I intend to try it on my dear little son.' Four years afterwards she had her daughter publicly inoculated in England; the experiment was then performed successfully on six condemned criminals at Newgate, and on the strength of these successful cases two children of Caroline, Princess of Wales, were inoculated, which gave a sanction to the practice.

Inoculation was not, however, thoroughly established for more than a quarter of a century after its introduction. It met with virulent opposition both from the medical profession and the clergy. A sermon is extant which was preached in 1722, by the Rev. Edward Massey, in which it is asserted that 'Job's distemper was confluent smallpox, and that he had been inoculated by the devil.' The great drawback to inoculation turned out, however, to be this: while it was invaluable to him who underwent the operation, and completely guarded him from the natural disease in its severe form, its effect upon the community at large was extremely pernicious in keeping alive the natural disease, and increasing its spread amongst those who were not protected by inoculation. While one in five or six of those who took the natural disease died, the average number of deaths at the Inoculation Hospital was only 3 in 1000; and yet, according to the authority of Heberden, in every thousand deaths within the bills of mortality in the first thirty years of the 18th century (before inoculation was at all general) only seventy-four were due to smallpox. The deaths from this disease amounted to 95 in 1000 during the last thirty years of the century; so that, notwithstanding the preservative effects of inoculation on almost all who were operated on, the total number of deaths from this disease increased in one hundred years in the ratio of about 5 to 4. At the beginning of the 18th century about one-fourteenth of the population died of smallpox; whereas at the latter end of the same century the number (notwithstanding, or perhaps rather in consequence of, inoculation) had increased to one-tenth; and this immense consumption of human lives was not the total evil, for many survivors were left with the partial or entire loss of sight and with constitutions destroyed. The benefits which were expected from inoculation were far from being realised, and smallpox would doubtless have gone on increasing in its destructive power if it had not been checked by Jenner's discovery of Vaccination (q.v.). Inoculation was forbidden by law in 1840.

Inowracław, called also HOHENSALZA and JUNG BRESLAU ('Young Breslau'), a town of Poland, 66 miles NE. of Posen, was Prussian till the Treaty of Versailles. Its chief industries are salt-mining, the manufacture of salt and machines, and iron-founding. Pop. 25,000.

In partibus infidelium (Lat., 'in the regions of the unbelievers'). Titular bishops in the Church of Rome were from the 13th century until the pontificate of Leo XIII. styled bishops *in partibus infidelium*. They were originally bishops who had no diocese, and took their titles from places where there was no longer a bishop's see. The usage originated after the Greek schism,

and became general in the time of the Crusades. The places conquered by the crusaders in the East were furnished with Roman Catholic bishops; but when these conquests were again lost the popes continued to appoint and consecrate the bishops as a continual protest against the power which had prevailed over their alleged right, and to signify their hope of restitution. But in Britain, the assumption of territorial titles being illegal and dangerous, the Roman Catholic bishops actually resident long bore titles derived from such distant places. In 1850 their assumption of titles from their actual sees gave prodigious offence in England, and led to the passing of the *Ecclesiastical Titles Act* (q.v.), which, however, remained a dead letter, and was repealed in 1871.

Inquest. See CORONER.

Inquisition, called also 'the Holy Office,' a tribunal in the Roman Catholic Church for the discovery, repression, and punishment of heresy, unbelief, and other offences against religion. From the very first establishment of Christianity as the religion of the Roman empire laws more or less severe existed, as in most of the ancient religions, for the repression and punishment of dissent from the national creed; and the emperors Theodosius and Justinian appointed officials called 'inquisitors,' whose special duty it was to discover and to prosecute before the civil tribunals offences of this class. The ecclesiastical cognisance of heresy and its punishment by spiritual censures belonged to the bishop or the episcopal synod; but no special machinery for the purpose was devised until the spread in the 11th and 12th centuries of certain sects, reputed dangerous alike to the state and to the church—the Cathari, Waldenses, and Albigenses—excited the alarm of the civil as well as of the ecclesiastical authorities. In the then condition of the public mind, however differently it is now constituted, heresy was regarded as a crime against the state, no less than against the church. An extraordinary commission was sent by Pope Innocent III. into the south of France to aid the local authorities in checking the spread of the Albigensian heresy. The fourth Lateran Council (1215) earnestly impressed both on bishops and magistrates the necessity of increased vigilance against heresy; and a council held at Toulouse directed that in each parish the priest and two or three laymen of good repute should be appointed to examine and report to the bishop all such offences discovered within the district.

So far, however, there was no permanent court distinct from those of the bishops; but under Innocent IV., in 1248, a special tribunal for the purpose was instituted, the chief direction of which was vested in the then recently-established Dominican Order. The Inquisition thus constituted became a general instead of as previously a local tribunal; and it was introduced in succession into Italy, Spain, Germany, and the southern provinces of France. So long, moreover, as this constitution remained it must be regarded as a strictly papal tribunal. Accordingly, over the French and German Inquisition of the following century the popes exercised full authority, receiving appeals against the rigour of local tribunals, and censoring or even depriving the inquisitor for undue severity. In France the Inquisition was discontinued under Philip the Fair; and though an attempt was made under Henry II. to revive it against the Huguenots the effort was unsuccessful. In Germany, on the appearance of the Beghards (q.v.) in the beginning of the 14th century, the Inquisition came into active operation, and inquisitors for Germany

were named at intervals by various popes, as Urban V., Gregory XI., Boniface IX., Innocent VIII., down to the Reformation, when it fell into disuse. In England it was never received, all the proceedings against heresy being reserved to the ordinary tribunals. In Poland, though established in 1327, it had but a brief existence.

It is the history of the Inquisition as it existed in Spain, Portugal, and their dependencies that has absorbed almost entirely the real interest of this painful subject. As an ordinary tribunal similar to those of other countries it had existed in Spain from an early period. Its functions, however, in these times were little more than nominal; but early in the reign of Ferdinand and Isabella, in consequence of the alarms created by the alleged discovery of a plot among the Jews and the Jewish converts—who had been required either to emigrate or to conform to Christianity—to overthrow the government, an application was made to the pope, Sixtus IV., to permit its reorganisation (1478); but in reviving the tribunal the crown assumed to itself the right of appointing the inquisitors, and, in truth, of controlling the entire action of the tribunal. From this date forwards Catholic writers regard the Spanish Inquisition as a state-tribunal, a character which is recognised by Ranke, Guizot, Leo, and even the great anti-papal authority Llorente; and in dissociating the church generally and the Roman see itself from that state-tribunal, Catholics refer to the bulls of the pope, Sixtus IV., protesting against it. Notwithstanding this protest, however, the Spanish crown maintained its assumption. Inquisitors were appointed, and in 1483 the tribunal commenced its terrible career under Thomas de Torquemada. The popes, feeling their protest unsuccessful, were compelled from considerations of prudence to tolerate what they were powerless to suppress; but several papal enactments are enumerated by Catholics, the object of which was to control the arbitrary action of the tribunal and to mitigate the rigour and injustice of its proceedings. Unhappily these measures were ineffective to control the fanatical activity of the local judges. The number of victims, as stated by Llorente, the popular historian of the Inquisition, is positively appalling. He affirms that during the sixteen years of Torquemada's tenure of office nearly 9000 were condemned to the flames. The second head of the Inquisition, Diego Deza, in eight years, according to the same writer, put above 1600 to a similar death; and so for the other successive inquisitors-general. But Catholics loudly protest against the credibility of these fearful allegations. It is impossible not to see that Llorente was a violent partisan; and it is alleged that in his work on the Basque Provinces he had already proved himself a venal and unscrupulous fabricator. Although, therefore, he has made it impossible to disprove his accuracy by appealing to the original papers, which he himself destroyed, yet his Catholic critics—as Hefele in his *Life of Cardinal Ximenes*—have produced from his own work many examples of contradictory and exaggerated statements; Prescott, in his *Ferdinand and Isabella* (iii. 467-70), has pointed out many similar instances; and Ranke does not hesitate (*Fürsten und Völker von Süd-europa*, i. 242) to impeach his honesty. Still, with all the deductions which it is possible to make, the working of the Inquisition in Spain and in its dependencies even in the New World involves an amount of cruelty which it is impossible to contemplate without horror. When it was attempted to introduce it into Naples Pope Paul III., in 1546, exhorted the Neapolitans to resist its introduction, 'because it was excessively severe and

refused to moderate its rigour by the example of the Roman tribunal' (Llorente, ii. 147). Pius IV. in 1563 addressed a similar exhortation on the same ground to the Milanese (*ibid.* ii. 237); and even the most bigoted Catholics unanimously confess and repudiate the barbarities which dishonoured religion by assuming its semblance and its name.

The procedure of the Inquisition deserves a brief notice. The party, if suspected of heresy, or denounced as guilty, was liable to be arrested and detained in prison, only to be brought to trial when it might seem fit to his judges. The proceedings were conducted secretly. He was not confronted with his accusers, nor were their names even then made known to him. The evidence of an accomplice was admissible, and the accused himself was liable to be put to the torture in order to extort a confession of his guilt. The punishments to which, if found guilty, he was liable were death by fire, as exemplified in the terrible *Auto da Fé* (q.v.), or on the scaffold, imprisonment in the galleys for life or for a limited period, forfeiture of property, civil infamy, and, in minor cases, retraction and public penance. It is fair to recollect that some of the usages were but the ordinary procedures in all the courts of the age, whether civil or ecclesiastical.

The rigour of the Spanish Inquisition abated in the later part of the 17th century. In the reign of Charles III. it was forbidden to punish capitally without the royal warrant; and in 1770 the royal authority was required as a condition even for an arrest. From 1808, under King Joseph Bonaparte, the Inquisition was suppressed until the Restoration; it was again suppressed on the establishment of the constitution of 1820; but it was partially restored in 1825; nor was it till 1834 and 1835 that it was finally abolished in Spain, its property being applied to the liquidation of the national debt.

The Inquisition was established in Portugal in 1557, and its jurisdiction was extended to the Portuguese colonies in India. The rigour of its processes, however, was much mitigated in the 18th century, and under John VI. it fell altogether into disuse.

The Inquisition in Rome and the Papal States never ceased, from the time of its establishment, to exercise a severe and watchful control over heresy, or the suspicion of heresy, which offence was punished by imprisonment and civil disabilities; but of capital sentences for heresy the history of the Roman Inquisition presents few instances, and, according to Balmez (*On Civilisation*), it 'has never been known to order the execution of a capital sentence' for the crime of heresy. The tribunal still exists under the direction of a congregation, but its action is confined to the examination of books and the trial of ecclesiastical offences and questions of church law; and since the Italian occupation of Rome in 1870 its supreme jurisdiction is limited to the Vatican.

See Llorente's *Historia Crítica de la Inquisición* (Fr. trans. 4 vols. 1817); Comte Joseph de Maistre's *Letters on the Spanish Inquisition* (Eng. trans. 1851); Prescott's *Ferdinand and Isabella*; Motley's works; Hefele's *Cardinal Ximenes*; Hoffman, *Geschichte der Inquisition* (1878); books on the Inquisition in France by Molinier (1880) and Tanon (1893); A. S. Turberville, *Medieval Heresy and the Inquisition* (1920); but especially H. C. Lea's *History of the Inquisition of the Middle Ages* (3 vols. 1888) and his *Inquisition in Spain* (4 vols. 1906-8).

Insanity. No good definition of insanity has ever been given in any language, nor is it possible. Any definition that would have accurately fitted what was understood as insanity in Shakespeare's time would be quite inadequate now, for we count

men insane who would have passed muster well enough in the 16th century. Another difficulty of definition consists in this, that the very same mental symptoms may exist in two people, and in one they may constitute true insanity, while in the other they may only be one of the brain symptoms of a fever. And if there is one thing better understood about insanity now than formerly, it is that there is no exact line of demarcation between insanity and sanity any more than there is between light and darkness. There is an undefined borderland through which most cases of insanity pass, between technical and legal sanity and insanity. But while this is true, there is no truth and little sense in the common saying that 'all are more or less insane on some point.' Such a statement entirely mistakes the real significance of insanity as a *disease*, and is a pernicious fallacy begotten of ignorance. Insanity may be reasonably described, according to the scientific ideas of our time, as 'such an alteration in any or all of the mental functions of the brain as makes a man unfit from this cause to do his work or manage his affairs, or mingle in the society of his fellow-men, or which makes him unsafe to himself or others or to society, this alteration not being solely the result of fever, but being the result of disease or disorder in the working of, or imperfection in the development of that portion of the brain through which mind is manifested.' In defining or describing insanity we wish to exclude the delirium of fevers, comatose conditions, somnambulism, mere eccentricity, hysteria, transitory brain excitements due to religious or other strong emotions, or due to other adequate causes. A mother who loses control over herself when she hears suddenly that a child is dead may be more sane than another who shows no outward sign of emotion on such an occasion.

Tests.—There is or can be no absolute test of insanity—or of sanity, for that matter. Sanity is best proved by normal self-control, and insanity by the loss of it from disease. The presence of one or more insane delusions was at one time the legal test, but it is not a true or scientific one. The 'knowledge of right and wrong' was at one time a legal test of responsibility, in other words of sanity, by the law, but it has long been given up. Half the lunatics know right from wrong in some degree or other.

Mind and Brain.—Although the relation of mind to brain must probably always remain a mystery, insanity cannot be properly studied except by reference to the mental functions of the brain. A psychological view of mind throws more light on the complicated and wondrous phenomena of this disease than any merely physiological view. Looked at from the human and social point of view, no other disease approaches it in the terror it inspires, the sense of helplessness it causes, the deep distress to relatives, and the disruption of all normal social conditions. A scientific view of it alone brings us into the mental and emotional attitude with which civilised humanity now regards disease in general. No progress was made in its study or treatment till physicians came to look at it in precisely the same way as they do ordinary disease. Without prejudice either to the materialistic or idealistic point of view, mind must be regarded by all students of insanity practically as being a 'brain function' which is found in all animals in varying degrees; which in man does not at one time of life manifest itself, then is seen to arise in small beginnings like any other function, then gradually to develop, attain maturity, and then fail and eventually disappear—all these conditions of mind being absolutely correlated with the structural development and decay of the mental organ in the brain. The latest physiological and evolutionary studies of mind

in relation to brain seem to lead to the conclusion on scientific and not merely *a priori* grounds that it is to the mental organ or centres in the brain that all higher evolution tends. In it are 'represented' every other organ and function of the body, which are all in intimate and organic connection with it and its highest function of mind, and with each other so as to make of the organism an organic unity. If the evolutionists are right, everything that lives tends towards mentalisation, and all the nervous organs of all the types of animal life find their acme in the mental centres of the human brain. The whole of the human brain is not a mental organ. There are centres for motion and sensation and regulation of function, but they are all represented in, and correlated and largely controlled by the mental organ. It clearly resides in the convolutions of the brain. This dominant organ has necessarily become what it is in man through the hereditary influences that have gradually upbuilt it since the beginning of life. This heredity has been largely influenced by external conditions. These have been good and bad throughout the ages, and the bad have left many bad mental results, in so far as natural selection and the struggle for existence have not eradicated them. The mental organ in the human brain has thus become the most complicated, the most delicate, and yet the most potent thing in nature, impressionable to all stimuli from within the body and outside it; reactive in due amount, and yet not unduly if healthy, to all these impressions and stimuli; containing within itself, in a way that yet we are not even able to realise, hereditary qualities, bad and good, from thousands of ancestors. If this is so one is prepared to believe that through evil hereditary influences, and from evil conditions outside it, this organ may often be upset in its normal working. The most important form of such upset is insanity, because it touches the highest brain function. The student of mind physiologically finds on the threshold of his studies that every form of mental energy is just as hereditary as the colour of the hair or the shape of the nose; he finds that volitional power, reasoning acuteness, emotional keenness, moral sensitiveness, good social instincts, retentive memory, and mental resistiveness of all kinds are all transmitted hereditarily. He is therefore prepared to believe that these same laws of heredity have determined the volitional paralysis, the reasoning and the emotional perversions, the losses of memory, and the mental instability which he finds among the insane, and to believe that it is probably the most hereditary of all diseases.

General Symptoms.—The symptoms of insanity are best studied as mental and bodily symptoms. It is only since the disease was studied from the physician's point of view that the bodily symptoms have been specially noticed. Nothing in medicine was ever seen till it was looked for. Nowadays every physician knows that the bodily symptoms and the general condition of the body and its organs are often the most important matters for him to observe and attend to in a case of insanity. He finds few cases of recent insanity without such bodily symptoms. The most common mental symptoms are morbid emotional depression and mental pain, which is the dominant symptom in melancholia. It is an essential law of life that in health the performance of all function yields pleasure. The law is that to live is to energise, and to energise is to enjoy life. Except this is so there is abnormality or disease. In many cases of insanity to energise mentally is to suffer pain. The essential relationship between emotion and action is thus reversed. Another symptom in other cases is an undue emotional exaltation; this is commonly

associated with a loss of the great controlling or inhibitory functions of the brain, and occurs in mania. There is morbid brain excitement, commonly exhibited in restless motions or shouting. Such cases may go on to complete loss of any consciousness of all the former brain impressions and mental life. The patient remembers nothing, and does not know his nearest friends. Another most common symptom is a diminution or loss in the power of attention. This is common to nearly all forms of insanity. Then we have perversion of the reasoning power, as seen most frequently in insane delusions. Like insanity, an insane delusion cannot be defined. It may be said to be 'a belief in something that would be incredible to ordinary people of the same class, education, or race as the person who expresses it, this resulting from some morbid state of the brain.' Insane delusions are common in most cases and varieties of insanity. They are divided into fixed delusions and changing delusions, the former being the most serious and incurable. Some delusions are held by patients in a sort of slack theoretical way, not influencing conduct; others again are keenly held and lead to their logical results in conduct. There may be two 'prophets of the Lord' in an asylum, one of whom will insist on delivering his 'message' on every opportunity to all with whom he comes into contact, will not employ himself in ordinary occupations, and refrains from all amusement: the other will only speak of his delusion when asked about it, will be a capital blacksmith or scrubber of floors, and enjoy thoroughly a dance or a comic song. The origin of insane delusions is one of the most interesting, and often the most obscure of psychological problems. In some cases the process can be clearly traced, being analogous to the process of 'day-dreaming' in children. Imagination and fancy are vivid, the reasoning and comparing power is in abeyance, and so the subjective is taken for the objective. Delusions more often arise from imperfect mental integration, in mentally ill-balanced individuals. In such cases separate systems of thoughts and beliefs are slowly built up, which co-exist in the mind with other sets of thoughts and beliefs which are of the same order as those of the rest of the society to which the person belongs. If anything happens to arouse to activity this separate delusional system it may dominate the personality and obtain expression by overcoming conscious resistance. It then becomes the expression of the conscious self, and is consequently inaccessible to self-criticism or refutation. Hallucinations arise from the same kind of dissociated systems of thought, and in exactly the same way, as delusions, with which they are intimately associated in emotional tone and content. The hearing of voices when no such exist is an example of a *hallucination*, which is used to denote special sense impressions that have no outward causes. Hallucinations may be of hearing, which are the most common and the most serious as an indication of incurability if long continued; of sight, the next most common and more likely to be recovered from; of smell and taste, which are rare, and not favourable. Hallucinations and delusions may occasionally arise out of real sensations, which are misinterpreted by the weakened brain—e.g. a man has been drinking, and has so disordered his stomach, and irritated its lining membrane, that he feels a constant pain there and a bad taste in his mouth, and he concludes that poison has been put into his food, adducing these real sensations as proof of his delusion. His mental centre had been disturbed in its working by the drink, so that he could no longer reason clearly and put the true interpretation on the facts.

A distinctive character of an insane delusion

is that it cannot be in any way changed or dispelled by the clearest demonstration that it is false. A man thinks he is ruined and a pauper; you bring his bank-book and show him that he has £1000 to his account; and you bring the banker with the actual money to him, but you cannot by such means eradicate the false belief. A sane man may have a hallucination (see *HALLUCINATIONS*), but he knows his 'brain is playing him a trick' when ordinary means are taken to demonstrate the unreality of his impression.

Obsessions and Impulses.—An obsession is a dissociated group of ideas which suddenly enters consciousness, disturbing the ordinary mental life, but not involving the personality of the individual. Obsession is to ordinary thought what impulse is to action. (1) Obsessions most commonly occur in neurasthenics, hysterics, and other degenerates, among whom, as a class, other forms of mental dissociation are generally found. (2) Obsessions may be independent of preceding emotions or any other known cause. (3) They may abruptly enter consciousness, often with startling suddenness, and remain there altogether beyond the control of the conscious mind. (4) They are recognised by the individual as foreign to his personality and his modes of thought, and are not, at any rate in most cases, blended with his personality. (5) There are as many forms of obsession as there are of thought. Some are harmless and meaningless, as, e.g., the desire to repeat certain words, to count objects of no interest, or to touch some article. Others are fateful to the individual or dangerous to other people, as the desire to kill, to commit suicide, or to steal. The fact that obsessions may be related to the primary instinctive tendencies, as they often are, in no way affects what has been said or the explanation given above. As thought leads up to action, so does obsession lead up to impulse or pathological action. The number of impulses, as of obsessions, is endless, but a few are so important that they must be mentioned—e.g. the suicidal impulse, the impulse to murder (homicide), to steal (kleptomania), and to drink (dipsomania). As a rule, preceding the impulsive action, there is mental distress, caused by the force of the obsession, which demands relief by a discharge into action. Against the performance of the action there is opposed the purposive resistance of the conscious will if the action should be judged harmful or anti-social. There thus arises a mental conflict which may cause the patient much suffering. If the obsession is sufficiently strong it overcomes the will-power and realises itself in action, after which there is usually profound satisfaction and a feeling of relief. This feeling is, however, soon followed by one of remorse if the action is shameful or anti-social. Of all the impulses in insanity suicide is the most common. It is commonly a symptom in melancholia, and usually goes with a depressed emotional state. But sometimes it exists by itself as a morbid impulse, unreasoning, unaccounted for, unexplainable. Sometimes patients attempt their lives when unconscious of what they are doing, and do not remember what they have done. Patients say that ideas of suicide come into their minds unsuggested in the midst of work and even of enjoyment. A desire to 'put an end to one's own life is physiologically the furthest away from health of any morbid mental symptom that can possibly occur, for it is a perversion of the primary instinct of all living beings—viz. the love of life, and the desire and effort to protect and preserve it.

One of the most common and most painful symptoms of insanity is a change of natural affection towards relatives. The 'mother forgets her sucking child'; the sister ceases to love the brother; and the husband dislikes or suspects

his wedded wife. This is not universal, but in nearly half the cases of insanity the affective condition is thus perverted or reversed. The memory is not necessarily affected in insanity. In many patients it is exaggerated: things come back with unnatural vividness. A man during simple mania could repeat most of the Psalms and many of Shakespeare's plays, which he never could when well. In some cases the memory brings back only the unpleasantnesses of past life, in others only the pleasant events, and in others there is no memory of past events at all during the attack. It is a constant source of anxiety to relatives whether patients remember the events that have taken place during their attack or their own sayings, feelings, or thoughts then. No rule can be laid down as to this. It depends on the nature of the attack, and especially on whether the power of attention is affected during its continuance. It is certain the memory of events that happened during the attack is usually blurred or distorted or hazy, even though as in some cases the patients affirm they 'can remember everything.' It is frequent that after recovery they speak of the events during the attack and their own feelings then 'as if it were a dream.' Sometimes the affective nature gets changed during an attack not only in regard to persons, but to books, scenery, and food. The appetites become perverted and changed; the social instincts are commonly altered. In a few cases these are intensified, but their usual discrimination is lost. Commonly, a lunatic is unsocial, and some cases are entirely asocial. The imaginative faculty is usually perverted, this being generally connected with the delusions present. In some cases an attack of insanity is a prolonged 'day-dream,' the condition being one rather of disjointed fancy than of coherent or constructive imagination. The normal law of association of ideas is usually altered. The same ideas do not suggest each other in sanity and insanity. The tendency is in insanity for ideas to suggest grotesque and incongruous things or trains of thought. The habits of life are notably changed in most cases, men and women becoming literally 'not themselves' in their ways and modes of living. The cleanly becomes uncleanly; the orderly man disorderly.

The chief bodily symptoms in insanity are the following. There is scarcely any symptom more common before and in the early stages of attacks than sleeplessness. 'Tired nature's sweet restorer, balmy sleep,' certainly departs when the terrible brain disturbance occurs, or is about to occur. It does not follow that because a man is sleepless he is going to be insane, but almost every kind of insanity is sleepless in its early stages. Nor does it by any means follow that sleeplessness is always the cause of the attack. It is rather in most cases an early symptom. The next bodily symptom in importance is morbidnesses of speech. On the patient's speech we chiefly depend for our diagnosis of most cases. Through it delusions are given expression to; it may be incoherent or partially coherent; it may be over rapid, slow, or entirely absent.

The skin, the hair, the perspiration, the liver, the heart, and the kidneys are often changed in working, and the temperature of the body altered during an acute or recent attack of insanity. Before an attack there are often pains or uneasy feelings in the head, which disappear when it comes on. The bodily sensations are notably dulled in most acute attacks. Patients will often cut or bruise themselves or undergo operations without feelings of pain. The body weight is rapidly lost, and the general nutrition almost invariably suffers. Thus it is seen that disease cannot attack the highest organ and function without

affecting also almost every other organ and function of the body. The higher brain centres and the peripheral organs act and react on each other, so that when the one is disturbed in action the others suffer.

Forms, Varieties, and Classification of Insanity.

—One case of insanity may differ from another in all its symptoms, mental and bodily, so that the two may have almost nothing in common except that in both the mind is affected from brain disorder. One case may be so near sanity that it needs an expert to say there is anything wrong; while another is 'raving mad' to any eye. One case is conscious that his mind is affected; another, much worse, believes he was never so well in his life. One case needs no control, and can do some work; another needs the control of others in all respects, and cannot do anything. One is perfectly safe to himself and others, while another is as dangerous as the popular 'madman' is supposed to be—as a matter of fact, half the insane are not dangerous at all, and very few of them are as dangerous as they are popularly supposed to be. The popular idea that the insane are all much alike is utterly wrong. Nothing is more common than for the doctor of an asylum to be asked such questions as—'Do your patients know where they are?' 'Are they the better for the visits of friends?' 'Do they enjoy each other's society?' 'Are they happy?' 'Do they like or dislike you?' 'Are they nice to do with?' To one and all of such questions the answer has to be—'They differ entirely from each other in all these respects.' Where there are differences it is the business of science to classify. Insanity has been classified most variously, but at the present time only one classification holds the field. The one is that in which the prevailing mental symptoms are taken as the basis of classification, the cases with similar mental symptoms being thrown together into each group. This was first done by Philippe Pinel, who was born in 1745 and died in 1826, was the physician to the great hospital for the insane at Paris, the Bicêtre, and who during the revolutionary period asked and got permission to remove the chains and manacles from his patients there. It is the 'mental classification,' and is used more or less by all physicians.

Manic-depressive insanity, as its name implies, is an affection in which attacks of mania and melancholia appear either singly, as a recurrence of each separate phase in the individual life, by alternation of each phase, or in the form of a cycle known as *folie circulaire*, in which the maniacal phase, the melancholic phase, and the lucid interval form more or less approximately equal periods of the cycle. The prospects of recovery from the individual attacks are always good, but periodicity and a tendency to recurrence and relapse is unfortunately a very common symptom in most attacks of this insanity. Nothing is more discouraging to those in charge of cases than this relapsing tendency; but it should not lead to despair of ultimate recovery, unless such relapses become regular and frequent for years. When this is the case the prospects of recovery are bad. Patients suffering from circular insanity lead three lives—one when they are in the melancholy stage, another when in the joyous, elevated stage, and another when nearly sane. Manic-depressive insanity is an affection of adolescent life, but once established it may be prolonged into adult life, and even into old age.

(1) *Melancholic Phase.*—This has emotional depression, or mental pain and sense of ill-being, as its leading and dominant symptom. There may in addition be loss of self-control, insane delusions, which are usually suggested by the depression or impulses towards suicide, as well as incapacity to

follow ordinary avocations. These distinguish it from sane melancholy. Suicide is the great risk in such cases, four-fifths of melancholics being suicidal. The chief of the bodily symptoms are apt to be thinness, weakness, a low nervous and nutritive tone, and stomach, bowel, and liver derangements. Melancholia forms about 30 per cent. of the insanity sent to asylums; but if the cases not sent to such institutions, but treated at home, are taken into account, it forms probably half the total number. It is by far the most conscious and the most manageable form of recent insanity on the whole, being the form next to sanity. Most other kinds of mental disease begin by some amount of mental depression. Of melancholic patients sent to asylums 54 per cent. recover; but a larger percentage than this recovers if the cases treated at home are also included, because, of course, it is the worst class that require asylum treatment. The recoveries from melancholia are the most complete of all forms of insanity. It would seem to be caused by a more entirely functional and dynamical brain disturbance than any other form of insanity that may leave no trace whatever behind it after recovery.

(2) *Maniacal Phase*.—The chief emotional forms of mental exaltation are joyousness and rage, and are commonly accompanied by muscular excitement, restlessness, sleeplessness; the speech tends to become incoherent, the conduct violent or uncontrolled; there are commonly delusions of many kinds. The symptoms range from a joyous elevation with talkativeness and mere want of common-sense and foolish conduct up to complete incoherence, delirium, and 'raving madness' or 'acute mania.' In such acute cases the temperature of the body may be raised; often there is rapid loss of body weight; 28 lb. may be lost in a week. The brain is often congested and hyperactive in acute mania, but this does not result from inflammation.

Paranoia is that form where insane delusions are the chief signs of the mental aberration. A man may have such insane beliefs of all kinds, utterly unfounded in fact and utterly unchangeable by the plainest demonstration of fact that they are false, without any general depression of mind or exaltation. The intellect is chiefly affected rather than the affective nature in such a case. There are almost no cases of a literal monomania or a morbid false belief on one subject alone. The delusions are morbid in a particular direction, the chief forms being *monomania of grandeur* or *pride* and of *unfounded suspicions*. Perverse interpretations of the conduct of friends or strangers is the common form of the latter. It is not very curable when the delusions get fixed; but in the early stage, and when dependent on derangements of the bodily health, it is often recovered from. This form of insanity, and delusion generally, is of great importance from a legal point of view, but not so much from the medical side.

Dementia præcox is a disease of puberty and adolescence, although it may appear for the first time in middle life. It consists of a variety of states and symptoms, the common characteristic of which is disintegration of the mental processes. This disintegration shows itself chiefly in the emotional and volitional spheres of mind. Delusions and hallucinations are almost always present; the judgment is generally affected; there is incoherent and disordered speech; and the conduct is often wayward, unreliable, and impulsive. Professor Kraepelin of Munich, who first described the disease, divided it into three forms, namely, (1) Hebephrenic, (2) Katatonic, (3) Paranoid. The hebephrenic form commences in late childhood, and

interferes with intellectual development, so that a brilliant scholar may gradually become incapable of learning, sink into apathy, and ultimately into a state of hopeless dementia. The katatonic form may begin with symptoms of unconventional or impulsive conduct, or with attacks of mania or melancholia, in which hallucinations of the senses are a prominent symptom, and in which various delusions, chiefly of a persecutory character, are common. The attacks of mania and melancholia differ from those in manic-depressive insanity in that there is more incoherence, less mental clearness, and, above all, a tendency to lapse into cataleptic stupor or katatonia. During the attack of stupor the patients are in a state of torpor, the muscles rigid; they appear to have no volition, and to be unaware of all impressions on their senses. In the slighter forms the patients are resistive, silent, and occasionally impulsive. The paranoid form embraces all those cases of dementia præcox who suffer chiefly from delusions and hallucinations of the senses. The patients believe that they are acted on by electricity, mesmerism, telephones, and gases. They hear the voices of imaginary people who are their persecutors. Corresponding to these hallucinations they express delusions of a somewhat extravagant and badly systematised kind, couched in words and phrases of a bizarre description. These three forms of dementia præcox are not always distinct the one from the other, but tend to run into each other in the same case. Dementia præcox is an unhelpful form of insanity, and only a small proportion of the cases make good recoveries. Consequently, over 70 per cent. of the insane are the subjects of it, because they tend to accumulate in asylums and other forms of care.

Secondary dementia is the state of mind where the memory is impaired, the reasoning weakened, the feeling diminished, the will especially lacking, the attention and curiosity far below normal, these changes having occurred in a person who had at one time been normally constituted. It is in fact silliness, want of mental force, imbecility not congenital but acquired. This does not usually occur as the first symptom of an attack of insanity, but as the sequel to such a disease as dementia præcox, when it is not recovered from; hence it is commonly called *secondary dementia*. It is in fact the incurable stage in which some mental diseases end. The demented patients live on for many years sometimes. Dementia is in fact a premature mental death with persisting bodily life.

General paralysis is a disease of syphilitic origin. It may occur in persons who have inherited syphilis or acquired it innocently. It is always incurable, getting progressively worse, gradually impairing and at length destroying speech, motion, mind, and, usually in about three years' time, life itself. In this form of insanity patients commonly have extravagant delusions of wealth and power. It is found chiefly in the male sex, in large cities and manufacturing places, and as yet is almost unknown in the Highlands and the country districts of Ireland. It is a disease of modern life, and is proved to be increasing. *Paralytic insanity* is that connected with apoplexies, softenings and tumours of the brain, which cause ordinary paralysis first, and one form of dementia afterwards. *Epileptic insanity* is that accompanying epilepsy in so many cases. It is often attended by great violence and irritability, and by danger to those around the patient. Many murders are committed by insane epileptics. It is now much more manageable than formerly under modern medical treatment, but is apt to recur after apparent recovery. It prevails most variously in different parts of the country. In Scotland only 7 per cent. of the insanity is

epileptic; in some southern and midland counties of England 25 per cent. is of this character. The true cause of this difference is unknown. *Syphilitic insanity* is the result of brain-poisoning by this terrible scourge of humanity. *Alcoholic insanity* is a very frequent form indeed. Alcohol is the exciting cause of many forms of insanity; but all the mental disease caused by alcohol is not alcoholic insanity. There can be no doubt that some brains are so prone by heredity to be upset in their mental function that it takes little to do it. If it is not a quarrel with a friend, it is a spree on bad liquor. True alcoholic insanity always has motor symptoms, such as tremblings, convulsions, impaired speech, &c., except *Dipsomania* (q.v.), one variety where the insanity consists in the craving for excessive use of liquor, and lack of control over this craving. Alcoholic insanity may be intensely acute or very mild, very short in duration or very long continued, or incurable. That caused by prolonged steady soaking is the worst.

Pregnancy, childbirth, and nursing are the causes of the *insanity of pregnancy, puerperal insanity, and lactational insanity*. These form 10 per cent. of mental disease in the female sex. They are the most curable of all forms, recovering in over 80 per cent. of the cases. *Puerperal insanity* occurs commonly within a fortnight of childbirth, and is the most acute and one of the most dangerous to life of all insanities, while the most curable, and is attended by the highest temperatures, sometimes reaching 105° F.

Insanity is always coloured and modified in its features and symptoms according to the time of life in which it appears. In early youth, when manic-depressive insanity and dementia præcox usually occur, the symptoms are pronounced and vigorous, and their manifestations used to be known as *adolescent insanity*. *Climateric insanity* occurs at the period of the 'change of life.' It is usually melancholic in character, and recovers in 53 per cent. of the cases under proper treatment and conditions of life. *Senile insanity* is typically seen in the *senile dementia* of extreme old age, when the memory and all the faculties have faded away. But spurts of mental excitement and mental depression, with sleeplessness and unmanageability at home, often occur before final dotage. These are often recovered from. They are a half-way house to dotage or a quick road to it.

A number of rarer and less important clinical varieties of insanity have been described. *Traumatic insanity*, from injuries to head; *anicmic insanity*, from thinness of blood; *diabetic insanity*; *insanity from Bright's disease*; *post-febrile insanity*, following all kinds of fevers, especially scarlatina; the *insanity of lead-poisoning*; and *myxædematous insanity*.

Causes of Insanity.—There can be no question whatever that a hereditary tendency is the chief predisposing cause of insanity. All sorts of disturbing influences to the brain bring out this predisposition into actual disease. No doubt 70 per cent. of all cases have an insane or neurotic heredity. Marriage of near relatives causes it if the stock is bad; not if it is good. Physical causes—especially toxic infections—affecting the body produce insanity in predisposed persons, but moral causes, such as continued anxiety and mental overstrain by their exhausting emotional effect, are more frequently assignable causes. For the production of a case of insanity there may be, and there usually is, more than one cause—e.g. (1) a man has a heredity; (2) he is at a critical time of life, or is run down in general health, or takes alcohol in excess; (3) he has a money loss, or domestic affliction just before his attack. A heredity to insanity does not mean a bad brain or a weak mind before the insanity

comes on. Often it is quite the contrary. It is not the fools that go off their heads.

Nature of Insanity.—No one now doubts that it is due to disorder of the mental function of the brain. The bodily aspect of it should, however, never be lost sight of by physicians and relations. Essentially it in no way differs from many ordinary diseases: it begins, runs a definite course, and ends like many common ailments. The exact pathology of many forms of insanity has not yet been ascertained; in many of the cases that die no abnormality can be found in the brain.

Treatment of Insanity—Asylums for the Insane.

—The general principles of modern treatment may be divided into *bodily* and *mental* or *moral*. The bodily treatment may be generally said to be to put all the organs and functions right if wrong; to get up the strength and fat of the body—the writer preaches the 'gospel of fatness' for all his insane and nervous patients; to restore the tone and right working of the nervous system; to restore the sleep; to give medicines that determine more blood to the brain in cases where there is too little, and to give those that diminish the brain's blood-supply in those where there is too much; to use suitable baths that soothe nervous irritation, and mineral waters; to invigorate and soothe by life in the open air; and to let off undue and morbid nervous energy by much exercise, gymnastics, and massage in some cases, and to secure complete brain and body rest for others. The mental treatment consists chiefly in careful observation, companionship, control, distraction of the mind from morbid thought and feeling by suitable occupations and amusements, and guarding against the dangers of suicide, homicide, and self-neglect. The whole nursing of insanity is a most difficult task, for which the best bodily, moral, and mental qualifications are needed.

In the more civilised countries of Western Europe and America the methods of treating and caring for the insane are, in the main, and with a few variations some of which will be mentioned, pretty much similar. Of the 160,725 insane persons in Great Britain and Ireland in the year 1920 about 83·6 per cent. were in asylums, 11·8 per cent. in workhouses, 3·9 per cent. in private dwellings, and 0·5 per cent. in criminal asylums.

The modern asylum had its origin in the prison or house of detention, from which it is slowly evolving into the hospital ideal. Up to the end of the 17th century public asylums in this country were few and far between, and where they did exist they were usually regarded as places of safe custody for those of the insane who were dangerous to themselves or to others. Where there was no asylum available the insane were cast into the nearest prison, where they were treated worse than criminals. Following new legislation in England in 1845 and in Scotland in 1857 special institutions for the care of the insane were erected in every part of Great Britain. These institutions, while ostensibly erected for treatment as well as for care, were essentially custodial; they provided insufficient scope for the classification of patients, for the adequate care of the sick and infirm, or for the reception and treatment of new and acute cases. About the year 1875 a new type of asylum was erected embodying more advanced views, in which hospitals and observation wards appear for the first time; walled airing courts for exercise are done away with; dining and recreation halls are provided; and the general comfort and well-being of the inmates is provided for in such well-ordered surroundings as a large institution is capable of. The last stage in the evolution of asylum construction took the form of what is known as the *segregate* or *village type*. It is exemplified

in the asylum of Altscherbitz, near Halle, in Prussia, Kankakee, Illinois, U.S.A., and in three recently erected asylums in Scotland—Bangour near Edinburgh, Kingseat near Aberdeen, and Dykebar near Paisley. These institutions are almost entirely composed of a varying number of villas. Attached to the central administrative block are hospitals for the sick and reception wards for newly admitted cases. In close proximity to these are groups of villas for patients requiring special supervision. At a greater distance are the villas for the quieter, more trustworthy patients, where supervision is graduated according to the mental condition until, in some of them, there ceases to be any official restriction upon the movements of those patients who possess sufficient self-control to observe the general regulations of the institution. It will be seen that this form of asylum is divided into a hospital known as the central section, and a chronic section known as the colony. The colony is the industrial section; and as agriculture is one of the most important industries having a bearing upon the welfare of the insane, both the structure of such an institution, which covers a large area, and the suitable employment of the patients demand the acquisition of several hundred acres of land, estimated at from a half acre to one acre per inmate.

That the evolution of asylums should cease at the stage described is very unlikely, and the indications are that further developments will affect the rough-and-ready methods under which, as at present, all persons whose mental condition gives rise to anxiety are indiscriminately clapped into asylums. Asylums are at best an expedient—the only one at present available—for dealing with the mass of insanity in a country. But the method is drastic, and the aggregate cloistered life, with its painful associations, is offensive and repugnant to many of those who are compulsorily subjected to it. Although it does not seem possible that the system can ever be wholly superseded, much could be done by timely preventive treatment and advice to anticipate the necessity for the indiscriminate committal to asylums of all persons who suffer from mental symptoms.

In the year 1890 the Glasgow Parish Council established observation wards for the treatment of incipient forms of insanity, by means of which between four hundred and five hundred persons are each year so far relieved as to obviate the necessity of sending them to asylums. Recently, through the generosity of the late Dr Maudsley, a hospital bearing his name has been erected in London with a similar object.

With these exceptions there is no provision in this country whereby a person, who is not rich, can receive advice or treatment for early symptoms of insanity without going to an asylum. Most of the Continental medical schools and the larger medical schools in the eastern states of America possess psychiatric clinics for the alleviation and treatment of early insanity, and for the instruction of the medical profession in its symptoms.

The public care of the insane in private dwellings has been carried out in Belgium for centuries in the famous colony of Gheel. In Scotland it has been officially recognised since 1857, and more recently it has been adopted in some of the French departments. In Scotland, where nearly three thousand patients are thus disposed of, it forms a regular part of the lunacy administration of the country. Patients residing with their own relatives are subject to the same inspection and regulations as those residing with unrelated guardians. All guardians are 'sanctioned'; where a house receives more than one patient the house is 'specially licensed'; all patients are visited twice a year

by the commissioners or deputy commissioners of the Board of Control, twice a year by the inspector of poor, and four times a year by the parish medical officer. The system is comparatively inexpensive when compared to the cost of asylum care, and the patients enjoy, within necessary limits, unrestricted liberty of movement, as well as the advantages of mingling in the social life of the family with whom they reside and the community around them.

The Lunacy Laws.—For the protection of the property of the insane, laws had to be made at a very early period. The first statute on the subject for England was passed in the reign of Edward II., and for Scotland in the beginning of the 14th century. Both had the same end in view. Property then meant land, and the primary duties of land were to the king and the country. If the man who held it from the king was unfit from mental incapacity to perform these duties, then the king had to resume possession or appoint another to take his place and do them. But the man's state could not be ascertained without a formal inquiry by a responsible official—the Chancellor—and the chief object of the early statutes was to provide for such an inquiry. If the man was found to be idiotic or furious, he along with his property passed into the care of his nearest male relative, and there was an end of him so far as the law went. In time some little care was bestowed on him as a human being, apart from his being an owner of land. The principle was afterwards adopted that the inquiry was to be held before a jury, the issue being determined by them, and the consequences of the verdict being carried out under the direction of the Chancellor. Between 1300 and 1889 at least forty statutes were passed in England relating to the insane, and something like eight or ten in Scotland. The most important of them all was the great English Lunacy Act of 1845, passed through the exertions of Lord Shaftesbury, the philanthropist. Its objects were entirely in the interests of the insane, and its effects have been most beneficial in England, while throughout the civilised world its influence for good has been felt. Under its provisions asylums have been erected for every county in England. A Board of Commissioners was appointed who inspect and report on every asylum, and see every insane person whether in or out of an institution; and every precaution was taken that the insane should be well treated, ill-treatment of them being severely punishable. Asylum administration is now regulated by the Lunacy Laws of 1890 and 1891. The Scottish statute of 1857 was founded on the English Act of 1845. Under it a Board of Commissioners was appointed for Scotland, and provision made for the insane of the counties that had no existing asylums. Scotland has much the advantage of England in the ease and economy with which the property of an insane person can be taken care of temporarily or permanently under the charge of a *Curator Bonis*, strictly responsible to the Court of Session. England holds to the old, cumbersome and expensive, but very efficient, system of a formal inquiry (*de lunatico inquirendo*) by a 'Master in Lunacy' in each case. If the patient is found incapable of managing his own affairs (*non compos mentis*), the Lord Chancellor appoints 'a committee of the person' to see to his comfort and proper treatment, and a 'committee of the estate' to manage his property. In addition to the statutes that regulate the care of the property and the persons of the insane, there are acts that provide for the protection of the public and the safe custody of insane persons who have committed crimes or are specially dangerous—the Criminal Lunacy Statutes—and there are three great establishments for criminal lunatics, one at

Broadmoor for England, one at Dundrum for Ireland, and one in connection with Perth General Prison for Scotland. Notwithstanding the facility with which the insane can be certified and committed to asylums, such precautions are taken by the law and by the boards of lunacy against their abuse that no case of illegal detention of a sane person on the ground of insanity in a public or private asylum was proved in the exhaustive inquiry into the subject by the select committee of the House of Commons in 1877.

Curability of Insanity.—If we judge by recovery from individual attacks, then it is fair to estimate that 40 per cent. of the patients sent to asylums are discharged recovered. Yet in recent years, owing largely to the increased number of senile patients admitted, the recovery rate has been slowly falling. If, on the other hand, we take a longer view the prospect is not so encouraging. Many years ago Dr Thurnam in his *Statistics of Insanity* laid down a formula which holds good until the present day. He said: 'Of 11 persons attacked by insanity, 6 recover and 5 die sooner or later during the attack; of the 6 who recover, not more than 2 remain well during the rest of their lives; the other 4 sustain subsequent attacks, during which 3 of them die.'

Mortality.—In this connection it must be borne in mind that, apart from acute forms of insanity, the insane are peculiarly liable to suffer from other diseases of the nervous system, from diseases of the heart and blood-vessels, and from tuberculosis. When it is added that an increasing number of persons labouring under senility are annually certified, it is no wonder that the death-rate is much higher than that of the general population. For the decade 1905 to 1914 the death-rate of the insane in the United Kingdom was 9.6 per cent., or about six times that of the general population.

Is Insanity increasing?—If by insanity is meant the number of the registered insane alone, then it is increasing by a process of accumulation, i.e. by a surplus of the annual admissions over the total annual removals by death and discharge. If, on the other hand, the mental unsoundness of the community is meant, then the question is meaningless, for, according to several authorities, the amount of mental unsoundness in a community is much larger than its registered insanity, while registered insanity itself varies from time to time in accordance with changes in the social and economical conditions of the community. The fact that the annual occurring insanity in Great Britain, i.e. cases certified for the first time, bear the fairly constant ratio to the population of 5 per 10,000, ought to allay any misgivings on the subject.

Medico-legal and Social Relations of Insanity.—Few persons have studied carefully the mental state of our criminal population but have come to the conclusion that crime is most closely related to mental defect in very many cases. Could we abolish the latter the former would shrink to small proportions. This does not assume that many or most criminals are technically insane persons. The law has been gradually altering its tests as to the amount of insanity that absolves from punishment for crime. Of old a man accused of crime had to be totally delicious or fatuous to be absolved from punishment. Now the power of controlling his actions is being gradually made the test. The law has thus approached, and at last coincides with, the scientific views of insanity. Society should have the keenest interest in the mental condition of its members. Soundness of mind is the most precious possession of a people, for there are innumerable degrees and kinds of mental and moral defects that fall far short of insanity, yet are intimately related to it, hereditarily and psychologically—defects that

weaken a people's power of work, diminish its moral force, and impair its social stability. It is one of the most deeply saddening and terrible of the facts in human history that of the men of genius who have raised and glorified mankind few have been without mental disease in their families, and many have themselves fallen victims to it. If it is true that as yet the mode of human development has been such that to get one man of genius nature had to sacrifice mentally many of his kindred, the world should pay some of the debt it owes to its poets and thinkers by an ungrudging care of such victims. To produce in the human brain the greatest mental strength without running the risk of liability to mental disease must be one of the essential problems of the future for the educationist, the sociologist, the politician, and the physician.

The chief modern authorities are: Clouston's *Mental Diseases*; Bevan Lewis's *Mental Diseases*; Maudsley's *Pathology of Mind*; Kraepelin's *Psychiatrie*; Stoddard's *Mind and its Disorders*; Maurice Craig's *Mental Diseases*; Bernard Hart's *Psychology of Insanity*; Rivers's *Instinct and the Unconscious*.

Inscriptions is the name given to records, not of the nature of a book, which are engraved or inscribed on stone, metal, clay, and similar materials. Since ancient documents committed to such destructible materials as papyrus, parchment, or paper have largely perished, inscriptions on harder materials are in many cases the sole sources of our knowledge of ancient history and of early languages; and, even when MSS. have been preserved by copyists, inscriptions, which preserve the original forms of the letters, are of supreme palæographical importance. A very large number of inscriptions are mortuary epitaphs. Others, usually the most important, are records of the events in the reigns of kings. Others are dedications of altars, temples, or aqueducts. Many are of a religious character, recording donations to temples or in honour of the gods. Others are commercial contracts, banking records, receipts for taxes scratched on potsherds, scribbings on walls (*graffiti*), imprecations, and inscriptions on seals, gems, or vases. A marble tablet found at Tell el-Obeid near Ur is claimed as the earliest dated document known. It records the foundation of the temple of the goddess Nin-Khursag by King A-an-ni-pad-da, son of the first king of the first dynasty of Ur, who reigned, according to some authorities, a little before 4000 B.C.

Semitic Inscriptions.—The old Semitic alphabet is connected by some with certain characters (c. 1500 B.C.) found at the Egyptian mines at Serabit el-Khadim in Sinai. On a bronze vessel, found in Cyprus, once belonging to the temple of Baal Lebanon, and now in the Bibliothèque Nationale at Paris, is a dedicatory inscription which, written in the reign of Hiram, king of the Sidonians, may be assigned to the 8th century B.C., though some would place it at the end of the 11th or the beginning of the 10th. Of about 890 B.C. is the Moabite Stone (see MOABITES), now in the museum of the Louvre at Paris. In the same collection is a long inscription on the black basalt sarcophagus of Eshmunazar, king of Sidon, assigned to the 5th or to the 3d century B.C. (see ALPHABET). Among other important inscriptions are a sacrificial tariff found at Marseilles; an 8th century inscription from Nora, in Sardinia; the dedication of a bronze altar by Yehaumelek, king of Gebal, found at Byblos, and probably dating from the 5th or 4th century B.C.; and numerous inscriptions found in Cyprus, including a bilingual which gave the key to the Cypriote writing (see PHENICIA). In the same alphabet is the Hebrew record in the tunnel which brought the water under Ophel to the pool of Siloam. It is assigned to the reign either of

Hezekiah or of Manasseh in the 7th century B.C. (see JERUSALEM). Equally noteworthy is the so-called 'Calendar Tablet' from Gezer, dated by some 8th, by others 6th century B.C. We have also a fragment of an inscription from Herod's temple at Jerusalem, and others from tombs near Jerusalem, which are earlier than the siege by Titus, and numerous earlier inscriptions from Jewish cemeteries in the Crimea, at Aden, Venosa, Arles, Tortosa, and Rome. At Palmyra there are numerous inscriptions dating from the 1st to the 3d century A.D., mostly written in the reign of Zenobia, and there are others in many of the museums of Europe. A Palmyrene inscription was found in 1878 at South Shields near the Roman wall. See PALMYRA.

At Nablûs there is a Samaritan inscription, written in the reign of Justinian, containing a version of the Decalogue. An Arabic inscription full of interest is one in Kufic characters inscribed with gold letters on blue-glazed tiles running round the Qubbet-es-Sakra, or Dome of the Rock, at Jerusalem, the great mosque erected by the Khalif Abdalmalik in the year 72 A.H. The Nabathean, or early Arabic alphabet, is used in numerous inscriptions on the rocks at Sinai, and also in the Hauran. From the neighbourhood of Aden come a large number of inscriptions in the South Semitic alphabet; and there are early Ethiopic inscriptions dating from the 4th and 5th centuries A.D. at Axum, in Abyssinia. Among Aramaic inscriptions of note are those from Sinjerli, in North-west Syria (8th century B.C.), from Arabissos-Yarapsun and Karaburna in Cappadocia, from Taima in North Arabia, from Taxila in India (4th century B.C., and throwing light on the origin of the Kharosthi alphabet), from many places in Egypt, and from Abydos, Nineveh, and from near Sivas; a Lydian-Aramaic bilingual inscription found at Sardis, and dating from about the 5th century B.C., is of first importance for the study of the little known Lydian language. At Haji-abad and Nakhsh-i-Rustam, near Persepolis, are a number of inscriptions of the Parthian and Sassanian kings. In one of them Sapor I. records his victory over the Emperor Valerian and the Roman army. These inscriptions are written in a script derived from the Aramean, and exhibit the oldest form of the Pehlevi alphabet. At Singan-fu, in China, is an inscription written partly in Syriac characters and partly in Chinese, dated in the year 781 A.D., and recording the introduction of Christianity into China by the Nestorian missionaries.

The *Corpus Inscriptionum Semiticarum* (1881-1911), a splendid and exhaustive work, was begun by the French Academy under the editorship of Renan. See also Schröder, *Die Phönizische Sprache* (1869); Gesenius, *Monumenta Linguae Phœnicie* (1821); the *Corpus Inscriptionum Hebraicarum*; and books on North Semitic inscriptions by Lidzbarski (1898) and Cooke (1903), on South Semitic by Hommel (1893).

Greek Inscriptions.—The mortuary records from the island of Santorin (Thera) in the Ægean may belong to the 8th, 9th, or even to the 10th century B.C. Of definite date are the records cut on the knee of one of the colossal statues at Abu-Simbel, near the second cataract of the Nile, by Greek mercenaries in the service of Psammetichus, king of Egypt. They date from the end of the 7th or the beginning of the 6th century B.C. These are followed by the records on the bases of the statues which lined the Sacred Way leading to the temple of Apollo, at Branchidæ, near Miletus. They are all earlier than the Persian war, and are assigned to the 6th century B.C. Of about the same date is the celebrated Sigæan

inscription from the Troad, now in the British Museum. Of the 5th century is the long and important inscription of Lygdamis, found by Sir C. Newton at Halicarnassus, which belongs to the time of Herodotus. After the Persian war Greek inscriptions became more numerous. Great interest, from an historical point of view, is that inscribed on the trophy erected at Delphi by the Greeks to commemorate the defeat of the Persians at Plataea. It is now in the Hippodrome at Constantinople, where it was placed by Constantine. Another inscription of historical interest is the dedication to the Olympian Zeus of a bronze helmet, which formed part of the spoils taken at the battle of Cumæ in 474 B.C., when the naval power of the Etruscans was shattered by Hiero I., king of Syracuse. It was found at Olympia by Sir W. Gell, and is now in the British Museum (see ETRURIA). It was the practice of the Greek states to affix copies of treaties to the walls of their temples. Several of these have been preserved. They are mostly between Athens and her allies, and belong to the 5th and following centuries B.C. One between the Eleans and the Heræans is, however, assigned to the middle of the 6th century B.C. It is engraved on a bronze tablet which was hung in the temple of Zeus at Olympia, and is now in the British Museum. To the 5th century belong the interesting records of the battles fought by the Athenians at Drabescos and Potidæa; also a list, now in the Louvre, of the Athenian citizens who fell in Cyprus and Egypt in the year 460 B.C.; several enumerations of the treasures deposited in the Parthenon; and detailed accounts relating to the erection and cost of the Erechtheum at Athens. The foregoing are among the most important Greek inscriptions of the early period. Those of later date are extremely numerous. It was a Greek inscription (2d century B.C.) from Rosetta (see *Egyptian Inscriptions* below) which gave the most important key to the reading of the Egyptian writing. An interesting inscription, written in Greek hexameters, was discovered in 1879 at Brough in Westmorland. It is in memory of a Syrian youth who is believed to have perished during the campaign of Septimius Severus against the Caledonians in the year 209 A.D. It is now in the Fitzwilliam Museum at Cambridge.

It is estimated that about 50,000 Greek inscriptions are known to scholars. More than 10,000 were published by the Berlin Academy in the *Corpus Inscriptionum Græcarum*, of which the first two volumes, edited by Böckh, appeared in 1828 and 1833; the third, edited by Franz, in 1853; the fourth, edited by Kirchhoff, in 1856; and an index in 1877. Kirchhoff, Köhler, and Dittenberger edited the *Corpus Inscriptionum Atticarum*, merged in the Berlin Academy's new *Corpus Inscriptionum Græcarum*. A standard selection is Dittenberger's *Sylloge Inscriptionum Græcarum* (1883; 3d ed. 1915, &c.). The chief historical inscriptions will be found in a handy volume, edited by Hicks and Hill, *A Manual of Greek Historical Inscriptions* (1882; 2d ed. 1901). The dialect inscriptions are given in Cauer's *Delectus*, and facsimiles of the inscriptions most valuable for paleographical purposes by Röhl, *Inscriptiones Græcæ Antiquissimæ* (Berlin, 1882). On the whole subject Larfeld's *Griechische Epigraphik* (1902-7, 3d ed. 1914, &c.) is a standard work. For the beginner, Röhl's *Imagines Inscriptionum Græcarum* (Berlin, 1883), a cheap and useful little book, and Reinach's *Traité d'Épigraphie Grecque* (Paris, 1885), can be recommended; see also Roberts and Gardner, *An Introduction to Greek Epigraphy* (1887, 1905); a fascicule (Paris, 1919) of Laurand's *Manuel des Études Grecques et Latines*; and the international periodical *Supplementum Epigraphicum Græcum* (Leyden, 1923 et seq.). See table at ALPHABET.

Hittite Inscriptions.—See HITTITES. The non-cuneiform inscriptions at Lake Van are by Sayce allied to Hittite sources (see VAN).

Cretan and Cypriote Inscriptions.—Peculiar interest attaches to the Cretan inscriptions discovered by Sir Arthur Evans from 1893 onwards, illustrating both the pictographic or hieroglyphic and the linear script of the early Minoan period, contemporary with the first Egyptian dynasties. None of these inscriptions have yet been positively deciphered. The Cypriote syllabary of the Mycenaean age in Cyprus has been shown to be related to the linear script of Crete and the South Aegean (see Evans, *Cretan Pictographs and Pre-Phoenician Script*, 1895; *Scripta Minoa*, 1909, &c.). The hope of proving relations between the Cretan and Hittite inscriptions has not been realised.

Lycian Inscriptions.—These inscriptions, dating from about 500 B.C., are in an alphabet partly derived from Dorian Greek with additional signs; their language, like that of the Carian ones, is peculiar or 'Asiatic.'

Latin Inscriptions.—The *Corpus Inscriptionum Latinarum* contains about 100,000 inscriptions. An inscription on a gold fibula found at Praeneste is dated from about 600 B.C.; a second, on a coffin found in the Forum, is not later than the 5th century B.C.; while a third, the 'Duenos' inscription, found near the Quirinal, is assigned to the early part of the 4th century B.C.; the letters in all these show a close resemblance to those of the Greek alphabet. Among later inscriptions those from the tombs of the Scipios (3d century B.C. and after), now in the Vatican Library, are of extreme interest.

Latin inscriptions are couched in a style of their own, consisting of regular epigraphic formulae, with conventional modes of expressing names, paternity, tribe, country, domicile, illegitimacy, adoption, naturalisation, and with abbreviated designations of status for freemen, freedmen, slaves, children, as well as of dignities and functions of all kinds in all the various grades of official life, military, civil, and sacerdotal. There are also conventional formulae for epitaphs; and others are employed for edicts, dedications to the gods, inscriptions on buildings, temples, aqueducts, and statues, as well as *sortes*, execrations, and theatrical *tesserae*. Besides formal inscriptions there are numerous *graffiti* scribbled on walls, such as those found at Pompeii, which have a literature of their own. As a specimen of the way of interpreting an ordinary Latin inscription, we may take the first three lines of No. 4114 in the *Corpus Inscriptionum Latinarum*. It begins thus: 'TIB. CL. CANDIDO. COS. XVIR. S. F. LEG. AUGG. PR. PR. PROVINC. H. C.' &c. These abbreviations are to be expanded as follows: *Tiberio Claudio Candido Consuli, Quindecimviro sacris faciundis, Legato Augustorum duorum, propretore Provinciae Hispaniae Citerioris*, &c. Mortuary inscriptions, which are extremely numerous, usually begin with some stock formula, such as D. M. S. (*Dis Manibus Sacrum*) or H. S. E. (*Hic sepultus est*), and end with a prayer or pious wish, such as O. S. T. T. L. (*Opto sit tibi terra levis*). The Eugubine Tables (q.v.) form the chief monument of the Umbrian dialect.

The *Corpus Inscriptionum Latinarum* (1863-1916), undertaken by the Berlin Academy and edited by Mommsen, Hübner, and others, runs, with supplements, to over 40 volumes. Good selections are those of Wilmanns (Berlin, 1873), Dessau (Berlin, 1892-1916), Willemsen (Berlin, 1913); and for fac-simile reproductions see works by Ritschl (Berlin, 1862), Hübner (Berlin, 1885), Diehl (Bonn, 1912). Good guides to the study are Sir J. E. Sandys, *Latin Epigraphy* (1919), and works by Cognat (Paris, 1885; 4th ed. 1914), Egbert (New York, 1896; new ed. 1908), Ricci (Milan, 1898), Lindsay (London, 1898). See also the periodical *Année Epigraphique*.

Etruscan Inscriptions. See ETRURIA.

Runic Inscriptions have been found in great numbers in Sweden, Norway, Denmark, Yorkshire, Cumberland, Kent, and the Isle of Man. Among

the oldest is one assigned to the 1st century A.D. on a rock near Trondhjem in Norway; and the Tune Stone, also in Norway, which is assigned to the 3d century. One of the most interesting is on a massive golden torque found at Buzeu in Rumania. This is a relic of the invasion of the Danubian provinces by the Goths in the 3d century. At Collingham, in Yorkshire, is a Runic inscription in memory of King Oswin, who was murdered in 650 A.D.; and there is another at Bewcastle (q.v.), assigned to the 7th or 12th century, in memory of King Alefrith, who died in 670. At Barnspike, in Cumberland, there is a rock with a long inscription recording the treacherous slaughter by Robert de Vaux, a Norman knight, of Gillhies Bueth, owner of the lands of Lanercost. The cross at Ruthwell (q.v.), near Dumfries, contains a portion of Cynewulf's poem *The Dream of the Rood*. In Ireland only one or two Runic inscriptions have come to light; the first on stone to be found on the mainland was discovered in 1916 at Killaloe Cathedral, Co. Clare. In Greenland, on the shores of Baffin Bay and Davis Strait, a few genuine Runic inscriptions have been discovered. They probably date from the 11th and 12th centuries, and were doubtless executed by Icelandic colonists or explorers. At Kensington, Minnesota, was found a rune stone dated 1362.

The best collection of Runic inscriptions is by G. Stephens, *The Old Northern Runic Monuments of Scandinavia and England* (4 vols. 1866-1901). A selection of the more important will be found in the *Handbook of the Old Northern Runic Monuments* (1884), by the same editor. There is a catalogue of Runic literature by H. Hermannson (Cornell University, 1918). See RUNES, OGAM, SCULPTURED STONES.

American Inscriptions.—Records, variously conjectured to be Runic, Punic, Celtiberic, or Numidian, have been found in the United States, notably on the Dighton Rock in Massachusetts, in the island of Monhegan off the coast of Maine, in the Grave Creek Mound in Virginia, and elsewhere. They prove, however, on examination to be either natural markings on the rock, or the half-effaced pictorial records of Red Indian tribes, or even inscriptions by early European colonists. Very different are the numerous hieroglyphic inscriptions found in stelae, altars, and buildings in the ruined cities of southern Mexico and Central America; very many came from Copán, Honduras. An inscription on a statuette from San Andrés Tuxtla, Mexico, is assigned to about 100 B.C.; one, known as the 'Leyden Plate,' on a small nephrite celt found just west of the mouth of the Molagua River, Guatemala, is dated about 60 A.D.; another, on a stela at Uaxactun, Guatemala, is placed in the year 66 A.D.; others are of later date; but in accepting the dates ascribed to Maya inscriptions it is to be remembered that the question of the correlation of Maya and Christian chronology has not yet been definitely determined; the highly complex character, however, of the earliest discovered inscriptions goes to show that Maya hieroglyphic writing must, before achieving that complexity, have passed through some long period of development. The inscriptions have only been partially deciphered, and in so far as that has been done, they have been shown, unlike almost all other known inscriptions, to be calendrical and astronomical in character, and, though chronological, yet devoid of the content of history; that content many look to further decipherment to reveal.

See E. W. Förstemann, *Zur Entzifferung der Mayahandschriften* (Dresden, 1887); J. T. Goodman, *The Archaic Maya Inscriptions* (London, 1897); S. G. Morley, *An Introduction to the Study of the Maya Hieroglyphs* (Washington, 1915), and *The Inscriptions at Copán* (with bibliography; Washington, 1920); also works by A. P. Maudslay and C. P. Bowditch.

Cuneiform Inscriptions.—These inscriptions, from which the contemporary annals of Babylonia and Assyria have been deciphered, form by themselves a vast department of study. The oldest may date from about 3000 B.C. One of the most notable is the great historical inscription of Darius Hystaspes, engraved on the perpendicular face of a rock, 400 feet above the plain, at Behistun, in Persia. It contains in cuneiform character a thousand lines of writing, in three languages, Persian, Proto-Medic, and Semitic Babylonian. Not only is it of immense historical importance, giving an authentic record of the events of the reign of Darius, but it is of great interest as having furnished the clue by which the cuneiform writing was first deciphered. Among other cuneiform inscriptions may be enumerated the Tell el-Amarna (q.v.) tablets representing the Asiatic correspondence of the Egyptian court about 1400 B.C.; the annals of Sargon from Khorsabad; the account of the campaigns of Sennacherib, engraved on a colossal bull at Koyunjik; the inscription of Samas-Rimmon, son of Shalmaneser, a contemporary of Ahab and Jehu; the inscription of Shalmaneser II., giving an account of the capture of Damascus; the long historical inscriptions of Tiglath-pileser I., of Sargon I., and of Esarhaddon, and the account of the Egyptian campaign of Assurbanipal, besides the inscription of Khammurabi, king of Babylon, which is older than the Exodus; of Uruk, or Naram Sin, of Nebuchadrezzar, of Nabonidus, his successor, and the extremely interesting inscription on the tomb of Cyrus. See ASSYRIA, BABYLONIA, BEHISTUN, CUNEIFORM.

The chief collection of cuneiform inscriptions is *The Cuneiform Inscriptions of Western Asia* (5 vols. folio, 1861–70), edited by Sir H. Rawlinson and E. Norris. See also King, *Assyrian Language* (1904).

Egyptian Inscriptions.—An inscription of Sent, a king of the second dynasty, who may be placed in the 4th millennium B.C., is among the treasures of the Ashmolean Museum at Oxford. The historical inscriptions of the 18th and 19th dynasties are the most numerous and interesting. The records of the Asiatic campaigns of Thothmes I. and Thothmes III.; of Seti I. and Rameses II., are all at Thebes. They are older than the Exodus, and constitute the chief materials from which the history of ancient Egypt has been reconstructed. Two of the faces of the obelisk called Cleopatra's Needle, now on the Thames Embankment, bear the name of Thothmes III., who first erected it; on the other two sides Rameses II. has caused his own name to be inscribed. On the wall of a temple at Karnak we have an account of Shishak's invasion of Judæa in the reign of Rehoboam. One of the latest of the Egyptian inscriptions is the Rosetta Stone, a trilingual record in Greek, hieroglyphic, and hieratic characters, engraved on a block of basalt. Its interest arises from the fact of its having afforded the chief clue by which Akerblad, Young, and Champollion were enabled to decipher the Egyptian writing. See EGYPT, HIEROGLYPHICS.

Indian Inscriptions.—These are extremely numerous, and historically are of peculiar importance in view of the absence in India of historical books. Many are grants to temples, engraved on copper plates; some are long poems and dramas of kings and court poets. In 1924 seals bearing inscriptions in a hitherto unknown pictographic script were discovered at Harappa (Punjab) and at Mohenjo Daro (Sind) in the Indus valley; these seals appear to be closely connected and approximately contemporary with the Sumerian antiquities of southern Mesopotamia dating from the 3d or 4th millennium B.C. Previous to their discovery the oldest known Indian inscriptions were to be found on coins of the 4th century B.C.,

and in the edicts (3d century B.C.) of Asoka (q.v.), the last-named surviving in various versions on pillars and rocks in different parts of northern India. Of later date are the inscriptions in caves, topes, and temples. The inscription (2d century B.C.) of king Kharavela in the Hathigumpha cave near Cuttack in Orissa and other inscriptions of like character are historical records of much value. There are also old Pali inscriptions in Burma, Java, and Ceylon.

The best collections of Indian inscriptions are in the *Corpus Inscriptionum Indicarum*, ed. Cunningham, &c. (1879–88, with later supplements); Burgess, *Archæological Survey of Western India* (1874–78), and *Epigraphia Indica* (1892–94); Burnell, *Elements of South Indian Palæography* (1878); Hultzsch and others, *South Indian Inscriptions* (1890–1920); also Müller, *Ancient Inscriptions in Ceylon* (1883); Wickremasinghe, *Epigraphia Zeylanica* (1912 et seq.); Holle, *Indische Alphabeten* (Batavia, 1882); and Bühler's *Grundriss* (1896; trans. 1904).

Insectivora (Lat., 'insect-eating'), an order of mammals, the members of which—shrews, moles, hedgehogs, and the like—are mostly terrestrial, usually nocturnal in habit, and small in size. They feed mainly on insects and small animals, and in adaptation to this diet, which often plays a useful part in the economy of nature, the summits of the molar teeth are beset with small conical tubercles. A few, such as the moles, burrow; a few—e.g. Potamogale—are aquatic; while the divergent Galeopithecus, if included in this order, has among its peculiarities that of gliding through the air (see FLYING ANIMALS). The majority, however, have the general habit of shrews. Though often externally resembling various rodents, the Insectivores are entirely distinct in their anatomy. Altogether over two hundred living species are known, and many fossils, especially from Tertiary strata. The Insectivora are themselves lowly mammals, but lead on to Bats.

See HEDGEHOG, MAMMALIA, MOLE, SHREW; Dobson, *Monograph of the Insectivora* (Lond. 1882); Th. Gill, *Synopsis of Insectivorous Mammals*; Bull. Geol. and Geog. Survey, U.S.A. (Washington, 1875).

Insectivorous Plants. There are several hundred species of Dicotyledons which in some way or other catch insects and use them for food, either digesting their bodies or simply absorbing the products of their decomposition. They are remarkable for the adaptations of structure and function by which the insects or other small animals are secured, and for their obvious approach to the animal mode of nutrition. For it is a familiar fact that all typical plants feed at what may be called a very low chemical level, obtaining the required carbon from the carbonic acid gas of the air, and the equally essential nitrogen from ammonia, nitrates, and the like in rain-water and soil; while animals, on the other hand, do not derive their carbon from simpler substances than starch, sugar, and fat, nor their nitrogen from a lower source than the albumens manufactured by other animals or by plants. The insectivorous forms, however, break down the distinction in so far as they feed like animals on substances at a high chemical level; and the unity becomes more striking as we recognise that many of the insectivorous plants exhibit marked sensitiveness, mobility, and digestive power.

Altogether there are nearly five hundred species of insectivorous plants, referable to about sixteen genera, and to half-a-dozen dicotyledonous orders. They are represented in every great geographical region, perhaps with the exception of the African wastes and the Argentine pampas. For convenience of treatment we follow Kerner in recognising

three sets: (1) those with pits or cavities, into which small animals enter, but from which they are unable to return—e.g. Bladderworts and Pitcher-plants; (2) those in which the insect-catching depends wholly on the viscidness of the leaves—e.g. *Drosophyllum*; (3) those which exhibit distinct movements which help to secure the insects—e.g. Sundew and Fly-trap.

1. *With Pit-like Traps*.—The Common Bladderwort (*Utricularia vulgaris*, ord. Lentibulariaceæ or Utriculariaceæ) is a

Fig. 1.—*Utricularia Graefiana*: a, section of bladder of *Utricularia neglecta*.

water-fleas, whether chased by their enemies, attracted by a slight mucilage, or prompted by fatal curiosity, clamber on the antenna-like bristles which project from and perhaps protect the bladders. So far they are safe enough, but if they push their way through the narrow door, they find within the bladder a prison and a tomb. Escape is impossible, death ensues, and the products of decomposition are absorbed by sucking cells (fourfold hairs) on the walls of the bladder. Towards the end of summer, when the water no longer swarms with crustaceans, the *Utricularia* begins to die off, the life is concentrated in terminal buds, the bladders fill with water, and the plant sinks to the bottom. Thence it rises again in spring with a fresh equipment of buoyant bladders. There are numerous species of *Utricularia*, of which several are aquatic like the above; while others, especially in the tropics, are terrestrial. The booty of course changes with the situation, but the general habit seems to be the same throughout. We can only mention an allied genus, *Genlisea*, which has traps of a different pattern, approaching those of the pitcher-plants.

Among the *pitcher-plants*, the most familiar belong to the genus *Nepenthes* (ord. *Nepenthaceæ*), which includes nearly forty species, widely distributed by swamps and jungle pools, 'from New Caledonia and New Guinea over tropical Australia to the Seychelles and Madagascar, over the Sunda Islands and Philippines to Ceylon, Bengal, and Cochin-China.' The young plant has a rosette of half-prostrate leaves, quite unlike those of the adult, with a terminal hooked crest overhanging a slightly hollowed broad lower portion. A stem shoots up, however, bearing other leaves, broad and spatulate in form, ending in a cylindrical tendril, which twists round adjacent branches and develops

terminally into a large cavity or pitcher. The tendrils gradually lift the stem, and over the pool there eventually hang dozens of pitchers. These vary in size from a couple of inches to about a foot,

Fig. 2.—Pitcher-plants:

A, *Nepenthes phyllamphora*; B, *Sarracenia purpurea*; C, *Darlingtonia californica*.

are usually brightly coloured with red, yellow, and purplish blotches, and bear two lateral flanges and a terminal lid, which opens when the pitcher attains its full size. Partly by the colour and partly by the honey glands of the lid and pitcher margin, insects are attracted; they sip the sweet secretion and venture farther down, only to land on an exceedingly smooth, waxed, slippery 'conducting surface,' whence they fall into the lower third or half of the pitcher, which contains water and digestive secretion. When an insect falls, the secretion is stimulated and becomes acid. As analysis has shown the presence not only of various acids (malic, citronic, formic) but also of a peptic ferment, the fluid is exactly like that of an animal stomach, and the result is the same.

Another well-known pitcher-plant is *Sarracenia purpurea* (ord. *Sarraceniaceæ*), widely distributed in swampy regions of eastern North America from Hudson Bay to Florida. A rosette of half-prostrate hollow leaves surrounds an erect flower-stalk. The pitchers are topped by a crest, which is decorated with reddish streaks, and disposed so that it catches rain-drops and lets them slide into the pitcher. Insects are attracted by the sweet secretion of glandular hairs on the lid or crest, wander farther down on a so-called 'conducting surface,' covered with downward-pointed hairs which forbid return, and eventually fall hopelessly into the water occupying the lower part of the pitcher. There they are decomposed and absorbed. Several inches of half-rotten insects are found at the base, rendering the water brown and putrid, and emitting a disagreeable smell. That digestion does not occur seems certain, and the fact is confirmed by Riley's observation that two insects—a fly (*Sarcophaga sarracenia*) and one of the *Lepidoptera* (*Xanthoptera semicrocea*)—brave the horrors of the trap in safety, and utilise the dungheap of rotten insects as a suitable place wherein to deposit eggs. The grubs, which would perish if digestion occurred, thrive well and eventually bore their way through the sides of the leaf. Birds occasionally discover the store of insects and rifle the pitchers with their beaks. While all the species of *Sarracenia* probably agree in being non-digestive,

they present considerable differences of structure, which we cannot here describe. Beside the above species—*S. purpurea*—may be ranked *Heliamphora nutans* (from Mount Roraima in British Guiana). In *S. variolaris* and in *Darlingtonia californica* (from the Sierra Nevada) the pitcher is capped by a helmet, so that no water can enter; the contained liquid must therefore be wholly a secretion, though still only putrefactive. Finally, *S. drummondii* and *S. undulata* are in external form almost nearer to *Nepenthes* and *Cephalotus* than to the other species of *Sarracenia*.

In the two species of *Sarracenia* last mentioned only some of the leaves are modified into pitchers, the others remaining green, lance-shaped, and unhollowed. So is it with *Cephalotus follicularis*

Fig. 3.—Pitcher of *Cephalotus follicularis*.

(Cephalotaceae, near ord. Ribesiaceae), which is restricted to a limited area near Albany in Western Australia. Here in the usual basal rosette only the lower leaves are pitchers, two inches or so in height, best adapted for catching ants and ground-loving insects. The outer surface bears ridges which help the insects up, and there are the usual attractions of bright colour and sweet secretion. Intoxicated, it may be, with the honey, or merely inquisitive and unwary, the visitors pass from the sides or from the half-open lid to the slippery though corrugated

margin, and thence fall into the liquid which fills half the pitcher. Endeavours to return are balked by a projecting shelf, by an area beset with stiff downward-pointed papillae, and by sharp spines round about the intumed margin of the collar. As the glandular secretion has an acid reaction and a solvent power, *Cephalotus* is also to be credited with true digestion.

In regard to the morphology of the pitchers, we shall simply cite the recent conclusions of Macfarlane: (1) The leaf in *Nepenthes*, *Heliamphora*, *Sarracenia*, and *Darlingtonia* is compound, and consists of from two to five pairs of leaflets; (2) there is a marked tendency to dorsal fusion of the leaflets from apex to base; (3) such fused leaflets are seen in the broad basal part of *Nepenthes* leaf, and in the flaps and lids of the various pitchers; (4) the pitcher itself is a deep dorsal involution of the midrib just above the termination of the fused upper pair of leaflets, except in *Cephalotus*, where, as Dickson clearly showed, it is an involution of the leaf-blade.

Very different from the pitcher-plants, and with appliances less involved for insect-catching, is the Toothwort (*Lathraea squamaria*, ord. Scrophulariaceae), a pale, chlorophyll-less parasite found in British woods, battenning on the roots of trees and shrubs. Excepting the flower-stalk, the stem is virtually underground; it bears suctorial roots and tooth-like leaves. The latter are hollow, and are entered through a narrow aperture by many kinds of small animals. These seem to be entangled in protoplasmic exudations within the leaf-cavity, find exit impossible, die, decompose, and are absorbed. Along with the toothwort ought also to be ranked *Bartsia alpina*, whose underground buds show a somewhat similar structure and carnivorous habit.

2. *Plants which catch Insects by Viscid Secretion without Pits or Movement.*—The best representative of this set is *Drosophyllum lusitanicum* (ord. Droseraceae), a native of Portugal and Morocco, growing with luxuriance in sandy or rocky places, to a height of about a span. The long linear leaves are richly beset with glands, many borne

on long stalks, red in colour, and copious in an acid, viscid, dewdrop-like secretion, the others invisible to the naked eye, without stalks, colourless, and with an acid, dissolvent secretion, which is only exuded in response to the stimulus of some nitrogenous substance. Insects of various kinds alight on the long leaves, knock off the drops from the stalked glands, move anxiously about knocking off more and more until they are thoroughly besmeared, and their tracheae choked. Giving up the struggle, they sink on to the surface of the leaf, where the sessile glands begin the dissolvent and absorbent process. Kerner notes that the insect-catching is so effective that the peasants about Oporto use the *Drosophyllum* in their dwellings as a convenient substitute for fly-paper.

3. *Plants which exhibit Distinct Movements in their Insect-catching.*—The Common Butterwort (*Pinguicula vulgaris*), belonging to the same order as *Utricularia*, is a widely distributed representative of a genus including about forty species, all growing on more or less marshy ground (see fig. at BUTTERWORT). From a rosette of plump glistening leaves there rises for several inches an upright stalk, bearing a beautiful two-lipped, spurred flower of a violet colour. The leaves have a distinct fungus-like odour, doubtless attractive, and are covered with glands, some stalked like miniature mushrooms, others almost sessile, both with a copious, viscid, acid secretion. This serves as 'insect-lime,' but, besides retaining the unwary midges, it finally digests them. Drops of rain may fall on the leaves, or pebbles may land there, but without noteworthy effect; a small insect, however, stimulates a copious flow of the fatal secretion. But there is also movement; for, when an insect is caught, the margins of the leaves slowly curl inwards for an hour or two, thus surrounding the booty, or shifting it nearer the centre, in any case exposing it to more glands. After digestion, the results and the surplus exudation are absorbed, leaving finally the undigested skin of the insect on the more or less dry leaf surface. More than 170 years ago Linnæus noted how the Lapps used the butterwort for curdling milk, a property due to a rennet-like ferment which the plant has in addition to the digestive or peptic. The antiseptic qualities of the ferments perhaps justify another old custom of applying the leaves to the sores of cattle.

Beside the butterwort on the marshy moor we are likely to find *Drosera rotundifolia* (order Droseraceae) or some other species of sundew. Again, we have a rosette of prostrate leaves, from amid which rises a stalk with inconspicuous whitish flowers. Very striking, and constant in the forty or so species, are the red glandular 'hairs,' 'tentacles,' or processes which grow at different lengths from the upper surface and margins of the leaf. These are complex little structures with a head of glandular cells, supplied by numerous water-cells (wood-cells or tracheides), and surrounded externally by a drop of viscid secretion. These tentacles are sensitive, mobile, secretory, digestive, and absorptive. To drops of rain they are indifferent, to irritant particles they may respond by increased secretion; but when a midge or a small particle of nitrogenous food is placed upon them, they become marvellously, though by no means rapidly, active. A living midge, fly, or some other small insect alighting upon the attractive leaf is forthwith entangled; as it struggles it becomes more hopelessly besmeared, and meanwhile the secretion becomes truly digestive or peptic. More than that, however, the 'tentacles' curve down upon the victim, first one, and then, after an interval of a few minutes, another, till all the two hundred or perhaps half of them close upon the dying prey.

The whole leaf may become concave if the booty is large, and then, after an hour or two of leisurely bending, the leaf looks like a closed fist. Many

Fig. 4.—Leaf of *Drosera rotundifolia* seen from above.

kinds of insects are thus caught, and even a dragon-fly may fall victim to the combined efforts of several adjacent leaves. The sensitiveness is finer than our most delicate nerves or balances, for a sundew hair will respond to a millionth of a grain of stimulating nitrogenous matter. The response is marked by the increased secretion and by the bending, while internal changes are traceable under the microscope passing from one cell to another down the tentacle. As one leaf may be seen with the

remains of a dozen insects, and as there are half-a-dozen or so well-formed leaves, the carnivorous diet of the sundew is often considerable, and it has been demonstrated that the yield of seeds is better in those which are able to gratify their natural appetite.

Venus's Fly-trap (*Dionaea muscipula*), which Linnæus called the miracle of nature, is in several ways a more elaborate insectivorous plant than any of the above, and is the climax of the order Droseraceæ. A native of the east of North America, with very local distribution, from Long Island to Florida, it grows on moorland, with a circle of more or less prostrate leaves round the base of a many-flowered stalk, which rises 4-6 inches from the ground. The leaves, about 4 inches in length, consist of a spatulate stalk, which is constricted to the midrib at its junction with the broad blade. The halves of the blade are movable on one another along the midrib, and close together as this volume would do if fitted with an automatic closing spring. Round each margin are twelve to twenty long teeth, which interlock in rat-trap fashion with those of the opposite side; the centre of the leaf bears numerous rosy digestive glands; and there are on each half of the blade three sensitive hairs, which rise obliquely, but bend flat on a basal joint when the leaf closes. The blade shuts up in 8 to 10 seconds when one of the sensitive hairs is stimulated, and if an insect is caught in the trap a profuse secretion is exuded from the glands. Digestion goes on for a week or a fortnight according to the size of the booty; finally the digested material and the secretion are absorbed, and the leaf then reopens. There is evidently division

Fig. 5.—*Dionaea muscipula*:
a, leaf.

of labour to a greater extent than in the sundew, for the marginal teeth, the sensitive hairs, and digestive glands have separate functions. The delicacy of sensitiveness, the rapidity of movement, and the copiousness of the digestive secretion are noteworthy, while it is also significant that Burdon Sanderson has detected electric currents similar to those observed in the neuro-muscular activity of animals.

Superficially somewhat like the bladderwort, in its leaf-structure very like *Dionaea*, is an aquatic plant, *Aldrovanda vesiculosa* (ord. Droseraceæ), at home in south and central Europe, flourishing in ponds and pools where clear water is warmed by the summer sun. A thin rootless floating stem bears whorls of peculiarly modified leaves, dies away at one end as it grows on the other, forms in autumn a concentrated terminal tuft, which sinks to the mud at bottom and hibernates. Thence it rises again in spring lightened of its stores of starch and with buoyant air-spaces. The leaves consist of a spatulate stalk and a broad blade, which folds along the midrib like that of the fly-trap. The margin is firm, with small teeth, which meet those of the opposite side when the leaf is closed; externally a few long bristles project; the surface bears numerous longish hairs and also small stellate structures; there are large and small glands. When the water-fleas, insect-larvæ, or even diatoms rest on the surface of the leaf, the half-blades close quickly as in the fly-trap, the victims are imprisoned, and, though they may remain alive for some days, there seems no doubt of their final absorption. Other species of *Aldrovanda* from Australia and Bengal seem to have the same habit.

Besides the true insect-catchers noted above, there are not a few plants—e.g. among the Saxifragæ, Sedums, and Primulas, on the glandular surfaces of which insects are often entangled. These plants suggest how the insectivorous habit might begin, and there are two species in the sundew order, *Roridula dentata* and *Byblis gigantea*, in which the insect-catching seems to be more than incipient. Among the possibly insectivorous forms we must also include a Brazilian fern, *Elaphoglossum glutinosum*, and several liverworts—e.g. *Anomoclada mucosa* and *Physotium cochleariforme*. Zopf has recently described an interesting fungus (*Arthrobotrys oligospora*) which catches small threadworms in its nooses, riddles their bodies with a growth of fine threads (hyphæ), and absorbs the tissues.

Utility.—The adaptations for catching and utilising insects are so numerous and effective, that we are apt to conclude too readily that the insectivorous habit is not only advantageous but necessary for the health of the plants. There are, however, several facts which suggest caution. Thus it has often been noticed that a leaf of sundew or fly-trap may suffer, and even die, from the effects of too big a meal, a serious enough objection to utility were the casualty not as rare in nature as it is common in experiment. More important is the difficulty raised by cultivators, who point to all sorts of insectivorous plants flourishing perfectly without any insect food. To this it can be retorted that the natural conditions of scanty nitrogenous supply are probably not observed in the greenhouse, but the facts force us to abandon belief in the necessity of the insectivorous habit. We can only maintain that it is normally advantageous, a conclusion confirmed in some cases by the decrease in the quantity and quality of the seeds when no insects are available. From this, however, we need not conclude that the insectivorous function is the complete or even the original function of any of the curious leaf-structures above described.

Physiological Summary.—(1) It is a familiar fact that sundew and butterwort generally grow among bog-moss on the moors, where the all-important nitrogenous compounds are partially locked up by the acidity of the peaty soil, hence difficult to obtain. The same relative scantiness in nitrogenous supplies is more or less marked in the habitats of other insectivorous plants, and doubtless renders them more dependent on their peculiar animal diet. All are said to be averse to the presence of much lime. (2) The diet is to some extent a matter of chance; both creeping and flying insects, small flies and even large moths, besides spiders, and centipedes are caught by the terrestrial and pendent traps. The aquatic bladderwort's most frequent victims are the small crustaceans known as Cyprids; while the subterranean *Lathræa*'s prisoners vary from the rank of mites down to infusorians. (3) The attractions of insectivorous plants are manifold; a mushroom-like odour in the butterwort lures insects which frequent fungi, and some of the others also appeal to the sense of smell; the 'dew-drops' of *Drosera*, the rosy patch on the fly-trap, the bright colours of many pitchers are obvious enough charms; while the frequent exudation of honey is the most direct lure of all. (4) In *Nepenthes* and *Cephalotus*, *Drosera* and *Drosophyllum*, *Dionæa* and *Pinguicula*, the bodies of the insects caught are digested, that is to say, chemically altered into soluble substances, which are absorbed by the cells of the leaf. The process agrees with animal digestion in the net result, and in the presence of a peptonising ferment and an acid. Too little is known about the ferment or ferments, and also about the various acids present; but there is no doubt in regard to their digestive activity. It is very important, however, to recognise, with Morren and others, that in plants digestion and the activity of ferments are by no means confined to the insectivorous forms. Thus the diastase which in germinating seeds, &c. turns starchy material into sugar is virtually the same as the ferment in the saliva, &c. of animals; similarly in both plants and animals there is an inverting ferment which turns cane-sugar into grape-sugar; there is also an emulsifying or saponifying ferment in plants, acting on fats and oils in a manner comparable to part of the rôle of the pancreatic juice. J. R. Green has described a rennet-forming ferment, comparable to that of the calf's stomach, not only in *Pinguicula*, but in the flowers of *Gallium verum*, in the stem of *Clematis vitalba*, in the petals of the artichoke, &c.; finally, a peptonising ferment has been detected not only in insectivorous plants, but in such diverse situations as the latex of *Carica papaya* and the seeds of *Vicia*. The protoplasmic changes of plants are comparable to those of animals not only fundamentally, but also in many details, and the insectivorous plants are not unique, but simply conspicuous illustrations of vegetable digestion. (5) There is no doubt that both the products of digestion and the results of decomposition are absorbed by the insectivorous plants. Large stomata, protruding papillæ, suctional 'hairs,' and other structures in the different plants are sometimes credited with this function, about which little definite information is yet forthcoming. An interesting, if hardly conclusive, corroboration of the absorbent activity is given by Clark, who fed *Drosera* with flies saturated in citrate of lithium, and some days later detected with the spectroscope the presence of the metal throughout the whole plant, in fact even in the flower. (6) The sensitiveness so marked in sundew and fly-trap is not of course unique, but is illustrated in the leaves, tendrils, stamens, stigmas, &c. of many plants, and may be compared—though we

cannot go much further—with that of animals. Both *Drosera* and *Dionæa* respond to various kinds of stimuli, but usually and most readily to that of nitrogenous substances. Darwin gives numerous illustrations of the sundew's sensitiveness to extremely homœopathic doses ('000095 of a milligramme) of nitrate of ammonia and the like. In the fly-trap the sensitiveness, as we have seen, is definitely localised in the six jointed hairs. (7) The movements of sundew, fly-trap, and *Aldrovanda*, like those in the leaves of the sensitive plant or the stem of the hop, the stamens of the barberry or the stigma of *Mimulus*, are associated with changes in the cells of the plant. It is easy enough to compare the movements with those of contracting muscles; but we are still far from being able to work out the comparison or determine the divergence. Four points may be noticed: (a) In the tentacles of *Drosera* the movement is associated with a visible change in the contents of the cells. Darwin described this, perhaps mistakenly, as 'aggregation of the protoplasm,' and compared it with analogous changes seen elsewhere. From what we know of movement in other plants, it is likely that the activity of the insect-catchers is connected with a change in the water tension or turgidity of the cells. (b) In the movement of *Dionæa* Darwin detected a measurable contraction or alteration of form; the same has been seen by Cohn, Haeckel, and others in the mobile organs of other plants, and at once suggests the change of form in muscle-fibres. (c) Though there is no trace of anything like the nerves of animals, there is no doubt that a stimulus provoking motion passes from cell to cell and from part to part in both sundew and fly-trap. (d) Finally, Burdon Sanderson has described a resting and an action current of electricity in *Dionæa*, and concludes that 'the property by virtue of which the excitable structures of the leaf respond to stimulation is of the same nature as that possessed by the similarly endowed structures of animals.'

Although our knowledge of insectivorous plants dates from 1768, when Ellis sent to Linnaeus a description of the fly-trap and its habits, structural investigations prevailed until Darwin in 1860 began the thorough experimental study of insectivorous plants, comparing their sensitiveness, mobility, and digestive powers with those of animals. Since then the physiological interest of these plants has been kept steadily in view, our analysis of their vital processes becoming with each year more complete. At the same time, the morphology, especially of the pitcher-plants, has been studied with great success. The most difficult question concerning the origin and evolution of the insect-catching structures and functions is still a problem of the future.

See the following general works from which a guide to the vast literature will be obtained: C. Darwin, *Insectivorous Plants* (1876); P. Geddes, article 'Insectivorous Plants,' *Encyclo. Brit.*; A. Kerner von Marilaun and F. W. Oliver, *The Natural History of Plants* (1898); J. Sachs, *Physiology of Plants*, trans. by Marshall Ward (1887); S. H. Vines, *Physiology of Plants* (1886); K. Goebel, *Pflanzenbiologische Schilderungen* (1898).

Insect-powder is a greenish-yellow powder having a slightly pungent odour. When genuine it is prepared by powdering the closed flowers of various species of *Chrysanthemum*, especially *C. coronopifolium*, *C. coccineum*, and *C. cinerariæfolium*. When dusted on fleas and other insects it soon stupefies and finally kills them, but whether this is due to subtle emanations from the oil or to the contact with the powder is undetermined. It is generally stated that the volatile oil does not possess this action, but when midges alight on a hand which has previously been rubbed with an alcoholic

tincture of the powder they become stupefied, and in many instances rapidly die. The powder is innocuous to man, although it is stated to cause partial confusion of ideas in those who sleep in a room in which much of it has been used.

Insects are numerically the largest class of animals, occupying among Invertebrates a position in many ways similar to that held by birds in the backbone series. Widely separated as birds and insects are in structural rank, they have many common characters: both are very rich in species, and exhibit marvellous variety within narrow range; both are capable of true flight, are on an average very active in habit, and abound in illustrations of gay colouring; both have highly developed sensory and nervous organs.

Like other Arthropoda (q.v.), insects have jointed bodies and limbs, an enveloping cuticle of Chitin (q.v.), a ventral chain of ganglia, and a dorsal brain. Like Peripatus (q.v.)—a survivor of the ancestral stock—and like the lower class of Myriopods, insects breathe by air-tubes or tracheæ, and are therefore included under the title Tracheata. But, contrasted with Peripatus and Myriopods, insects have made two great steps of progress: the body is centralised, with locomotor limbs reduced

Fig. 1.—Disarticulated Beetle:

A, the head; F, the abdomen; between A and F, the three rings of the thorax; *a*, maxillary palps; *b*, labial palps; *c*, mandibles; *d*, antennæ; B, prothorax, with first pair of legs; C, wing-coverts or elytra; D, functional wings; H and I, two posterior pairs of legs; E, coxa of leg, with projecting trochanter; *e*, femur; *f*, tibia; *g*, tarsal joints.

to three pairs (whence the term Hexapoda), and all the typical average forms have wings. The concentration is seen in the reduced number of rings or body-segments, in the absence of developed appendages on the hind-body (or abdomen) of the adults, in the complexity of the mouth-appendages, and in the gathering together of the ventral nerve-centres. In many cases, however, the progress is emphasised only in the fully-formed insects, for the caterpillar in the absence of wings, with less compact nervous system, with more numerous and primitive appendages, &c., recapitulates an ancestral stage.

To sum up, insects are Arthropods, which are usually winged in adult life, breathe air by means of tracheæ, and have frequently a metamorphosis in their life-history. The adult body is divided into (1) a *head*, with three pairs of appendages (= legs), plus a pair of pre-oral outgrowths, the antennæ or feelers; (2) a *thorax*, with three pairs

of jointed legs, typically plus two pairs of dorsal, compressed sacs—the wings; (3) an *abdomen*, without legs, except in so far as these are rudimentarily represented in stings, ovipositors, and the like. It is impossible at present to give any secure estimate of the number of insects, though it is probably safe to say that they exceed all other animals taken together. Over 80,000 species of beetles or Coleoptera and about 15,000 moths and butterflies have been recorded; and Speyer estimates the total census at 200,000, while M'Lachlan concludes that future entomological industry will raise the sum total of insect species to a million.

Structure and Functions.—The anatomy and physiology of insects will be discussed together, and that as tersely as possible, referring to the articles ANT, BEE, BUTTERFLY, &c. for illustrations, and to the works cited for details.

Form.—The body of an insect consists of a distinct, undivided head, probably composed of four obscured segments, of a thorax with three divisions (pro-, meso-, and meta-thorax), and of an abdomen typically with eleven rings. In detail, however, the varieties are legion; thus, the thin-waisted wasp contrasts with the cockroach, the lank gnat with the compact bug, the graceful May-flies with the somewhat ungainly locusts, the minute midges with the Goliath beetles and humming-bird moths.

Appendages.—The jointed feelers or antennæ, which are outgrowths of the head, not strictly comparable to legs, have often numerous nerve-endings, and seem to be used in smelling, as organs of touch and guidance, and also in caressing or in communicating impressions to friends. Exactly comparable with legs are the three pairs of mouth-appendages, projecting downwards or forwards from the head, to which they are jointed and from which they are worked by muscles. The first pair—the mandibles—have but one joint, and are without the lateral 'pulp' present in the crustacean organs of the same name. They are biting and chewing organs, and are more or less reduced in those insects which suck. Next come the first pair of maxillæ, which have jointed 'palps.' The second pair of maxillæ are united at their base, and form the so-called labium, also provided with palps. In the different orders, and in association with the diverse diet, these three pairs of mouth-organs vary greatly, as may be seen by comparing those of cockroach, house-fly, moth, and bee. In connection with the three pairs of legs on the thorax, it is necessary in identifying insects from a manual to become familiar with the division of the limb into coxa, trochanter, femur, tibia, and tarsal joints, terms fancifully taken over from vertebrate anatomy. The claws and pads at the very tip, the tarsal hairs and glands utilised in adhering to smooth surfaces, and the occasional use of the legs in producing sounds ought to be noticed, as also such contrasts as are illustrated in the muscular legs of the cricket, the long, lank limbs of daddy-long-legs, and those adapted for

Fig. 2.—Mouth parts of Cockroach (after Savigny):

a, labrum; *b*, mandibles; *c*, first pair of maxillæ, with *d*, stipes; *e*, lacinia; *f*, galea; *g*, maxillary palps; *h*, sub-mentum of second pair of maxillæ or labium; *i*, mentum; *j*, labial palps; *k*, paraglossæ; *m*, lacinia; the last two together forming the ligula.

be noticed, as also such contrasts as are illustrated in the muscular legs of the cricket, the long, lank limbs of daddy-long-legs, and those adapted for

swimming, as in the water-boatman. Though larval insects often have rudimentary limbs on the abdomen, only hints of legs are seen on that region in the adults. Such hints we find in the lowest wingless insects (*Thysanura*), and at least plausibly in stings and ovipositors.

Wings.—The adult insect usually bears two pairs of dorsal outgrowths or wings on the two posterior rings of the thorax. These are flattened sacs, really double, worked by muscles, traversed in various patterns by 'veins,' which include air-tubes, nerves, and vessel-like continuations of the body-cavity. They are undeveloped in some passive females, and are likewise absent from many parasitic forms, such as lice and fleas. In these cases the wings have been lost, while they have never been

Fig. 3.—Cross-section through the Thorax:

a, tergum; b, wing; c, epimeron or upper part of side; d, stigma or spiracle; e, episternum or lower part of side; f, leg; g, sternum; h, nerve-cord; l, alimentary canal; k, trachea; i, heart.

attained by the lowest insects—the *Collembola* and *Thysanura*. When at rest the wings are usually folded in various ways, but the dragon-flies and some others keep them expanded. The two pairs may be almost alike, as in bees and butterflies; those in front may be merely covers (*elytra*) for the hind pair, as in beetles, or contorted rudiments in the little bee-parasites (*Strepsiptera*); the hind pair may be linked to the fore pair, as in *Hymenoptera*, and are rudimentary 'balancers' or 'halteres' in flies. They are often hairy or scaly, or gorgeous with pigment, or occasionally odoriferous. Professor Eimer has shown that the colouring and marking of butterfly wings serve as indices of the progress and relationship of species. As to their origin, it seems plausible to compare them to the tracheal outgrowths seen in some aquatic larvae, and to regard them as primarily respiratory and secondarily locomotor. One may venture to suggest that the additional respiratory efficiency derived from such outgrowths would increase the total activity of the insect, and more or less directly lift it into the air.

Locomotion.—Insects are emphatically locomotor animals. 'They walk, run, and jump with the quadrupeds; they fly with the birds; they glide with the serpents; and they swim with the fish.' Even the limbless larvae of many forms move deftly, contracting their bodies, and utilising jaws, hairs, and tubercles to help them along. Some will even jump to a relatively enormous height of six inches or more, by taking their tails in their mouths and letting go suddenly. The limbed larvae,

Fig. 4.—Thorax and part of the Abdomen of an Ephemerid Larva (from Lang, after Graber):

a, rudiments of posterior wing; b, c, d, tracheal gills; e, f, rudiments of anterior wings; g, longitudinal tracheae; to show close analogy between wings and tracheal gills.

and especially the true caterpillars, often move with great rapidity; a few jump, and many climb; others utilise their silken threads in spider-like fashion; while the young dragon-flies propel themselves along by the forcible expulsion of water. Even some pupæ move about, but the triumphs of locomotion are seen in the adult insects. Reference must be made to such a work as the *Introduction* of Kirby and Spence, and recourse had to actual observation, if any adequate conception be desired of the variety of ways in which insects walk, run, climb, swim, burrow, and fly. In connection with the flight of insects it may be noticed that the movement of the wings does not essentially differ from that of birds, that motion in a vertical direction is particularly easy, that steering is more difficult, especially since the very lightness of the bodies of insects make them liable to be blown about by the wind. Marey calculates the approximate number of wing-strokes per second at 330 for the fly, 240 for the humble-bee, 190 for the hive-bee, 110 for the wasp, 28 for the dragon-fly, 9 for a butterfly (see *FLIGHT OF ANIMALS*).

Skin.—Insects resemble other Arthropods in having a firm chitinous cuticle formed from the epidermis or hypodermis (see *CHITIN, CUTICLE*). The cuticle bears scales, tubercles, and hairs, of which the last are sometimes olfactory or otherwise sensory. In spite of the ensheathing armature there are often glands in connection with the skin—witness the salivary glands opening near the mouth in almost all insects, the silk or spinning glands of many larvae, especially of such as make cocoons, the odoriferous glands of bugs and beetles, the poison-glands of the stinging ants, bees, and wasps, the wax-glands of some Aphides, *Coccus* insects, and bees. Before the full size is reached there are skin-castings or moultings, often numerous. The muscular system is almost always highly developed. The muscles which work the legs and mouth-organs, raise and depress the wings, influence the income and expiration of air, control the circulation, and move the segments of the body on one another are most important. The nervous system consists, as in other Arthropods, of a complex dorsal brain or supra-oesophageal ganglionic centre, supplying eyes and feelers, and of a double ventral chain of nerve-centres. From the first ventral (or sub-oesophageal) ganglia, connected with the brain by a ring round the gullet, the mouth-appendages are innervated. In many insects the ventral chain is centralised in a few ganglia, and is usually more concentrated in the adults than in the larvae.

Sense-organs.—Except in fleas, lice, and the lowly *Collembola*, adult insects have compound eyes. These are often associated with simple eyes or ocelli, which are all that ever appear in larvae or in the three sets of insects mentioned above. Blind insects also occur along with other blind animals in the darkness of caves. Auditory organs are represented in almost all orders by peculiar nerve-endings ('chordotonal' and 'tympanal' organs) superficially disposed on various parts of the body. On the tactile antennæ, and probably also on the maxillary palps of various insects, there are specially innervated skin cells and hairs believed to be olfactory in function; while others more within the mouth are credited with gustatory sensitiveness. The skin of insects seems in certain regions to be sensitive to the differences of light and shade, so much so that some speak of a sixth or 'dermatoptic' sense. Much experiment and observation is still required on the senses of insects, and we can only mention such general facts as the following. There is sometimes both optic and auditory sensitiveness to impressions which are beyond the range of human sight and hearing; in flower-visiting and other insects there

is abundant evidence of sensitiveness to fragrance and colouring, and smell probably aids greatly in that prompt recognition of friends, kindred, or foes which the social insects so well illustrate; there seems little doubt that the power of forming distinct images of external objects, after our fashion of seeing, is very slight in insects. The student should refer to the work of Sir John Lubbock (Lord Avebury) on *The Senses of Animals* (Inter. Sci. Ser., 1888). Similarly, to return to the functions of the nervous system, we can only notice that, in addition to the numerous and often subtle instincts which are ingrained in the constitution of many species, there is indubitable intelligence, as seen in the reasonable adaptation of means to novel ends; that, as in other animals, the intelligence is greatest in the social insects—especially the ants and bees, where it is associated with complex, though very small, brains. There is also plain evidence of emotion—e.g. in the love-making and parental affection of many insects. See ANT, BEE, BUTTERFLY, INSTINCT, EYE, and especially the works of Avebury and Romanes.

Alimentary System.—The alimentary canal always consists of fore-, mid-, and hind-gut (see GUT), of which the first and the last portions are lined by a thin layer of chitin continuous with the external cuticle. But the length and structure vary not a little in different insects, to some extent in association with the differences of diet. The fore-gut includes mouth, pharynx, and gullet, of which the latter may be swollen into a crop, or bear an appended pouch (so-called sucking stomach), or be continued into a gizzard with hard grinding plates. The mid-gut is glandular, digestive, and absorptive; it often bears saccular outgrowths or glandular caeca, and has, as its (endodermic) origin implies, no chitinous lining. In Coleoptera, for instance, its length, which is usually inconsiderable, varies inversely with the nutritive and digestible qualities of the food. The hind-gut is often coiled, terminally expanded in the rectum, and in that region sometimes associated with glands. Its general function is absorption, while from it there spring excretory tubes or Malpighian vessels (see *infra*).

As to the food of insects, many are vegetarians, many carnivorous, a few mix both diets; many feed on the juices of living organisms, others only on putrescence; many actively rifle flowers of their nectar and pollen, or hunt for other insects with great activity, while not a few are external or internal parasites upon higher animals; the ant-lion digs a pit into which its unwary prey may fall, while dragon-flies attack their winged booty with open violence; among ants some

milk the aphides, while others are so degenerate in prosperity that they are actually fed by their slaves. Nor should it be forgotten that some of the higher insects lay up stores of food, usually with

parental instinct for the sake of their young, and that the eggs are often laid in the midst of the food suited to the larval appetite, even in cases where the adults may perish before the young are hatched.

Respiratory System.—Insects when resting often show panting movements in the abdomen, which is swayed by muscles whose activity is the chief condition of the circulation of air throughout the body. For in all insects the whole body is penetrated by air-tubes or *tracheæ*, which send fine branches into all the organs and tissues. These tubes are really ingrowths from the skin, and are lined by chitin, raised in what appear to be spiral thickenings which keep them elastically tense.

In most cases these tracheæ open to the exterior by paired apertures or *stigmata* on the breast and abdomen, often guarded by hairs and very variously disposed. There are never more, and usually fewer, than ten pairs of openings, though primitively there was probably a pair to each segment. In aquatic larvæ the tracheæ do not open (if they did the insect would drown), but are spread out on lateral or terminal expansions (tracheal gills), through the thin skin of which the oxygen dissolved in the water is absorbed (see DRAGON-FLY, EPHEMERA, GILL). The very efficient respiration of insects is one of the facts to be kept clearly in view in estimating the general activity of their life.

Fig. 6.—Portion of a branching Air-tube or Trachea, showing the internal chitinous ridges.

Here we may notice that many insects produce sounds which often express a variety of emotions. Thus, we have the whirr of rapidly-moving wings, as in flies; the buzz of leaf-like appendages near the openings of the tracheæ in many Hymenoptera; the scraping of legs against wing-ribs, as in grasshoppers; the chirping of male crickets, produced by rubbing one wing against its neighbour; the shrill piping of the male Cicadas, which have a complex drum-like instrument; the voice of the death's-head moth, due to the emission of air from the mouth; and the tapping of the death-watch knocking on external objects. In some cases, where not simply automatic, the sounds serve the alluring purpose of love-songs; they may also express fear, anger, and (according to Kirby) even sorrow, or they may give alarm and convey tidings.

Circulatory System.—As the tissues are riddled with air-tubes, the need for definite blood-vessels is greatly lessened, and so the circulatory system is slightly developed in comparison with the literally thorough respiratory arrangements. The blood—which is colourless, yellow, greenish, or even reddish, with amoeboid cells—flows for the most part along lacunæ without definite walls. There is, however, a central organ, the dorsal blood-vessel or heart.

Within the *body-cavity* of the insect there is often a characteristic mass of tissue known as the 'fat-body.' This is an important accumulation of reserve material, most abundant in the larval stages. In some cases the fat-body of the larva is rich in fat and poor in waste (urate) crystals, while that of the pupa is the reverse, showing that the material is used up in the reconstruction or metamorphosis. In a few insects, such as Fireflies (q.v.) and glow-worms, part of the fat-body seems

Fig. 5.—Anatomy of Honey-bee (after Leuckart):

to become the seat of phosphorescence, the light of which is in many cases a brilliant love-signal. See PHOSPHORESCENCE.

The *excretory system* consists of a set of fine tubes, or it may be threads, which grow out from the upper part of the hind-gut, and wind about often at great length in the body-cavity. The component cells contain abundant waste-products. In different insects the excretory or malpighian tubes vary greatly in number (2-150), and also in the manner of their connection with the gut. The usual type of invertebrate kidney—the nephridium—though persistent in Peripatus (q.v.), is not clearly discoverable in insects.

Reproductive System.—The sexes are always separate in normal insects; and the Hermaphroditism (q.v.) which casually crops up is in most cases only superficial. In both sexes the reproductive organs are paired, and the products pass out by paired ducts. The latter—the oviducts of the female or the *vasa deferentia* of the male—always open near the end of the abdomen, and, except in the Ephemeroidea, by a single aperture: it is possible that they represent modified 'nephridia.' Accessory external and internal structures in the males may assist in copulation or in making the spermatozoa into packets; of similar structures in the females the most important are the occasional external ovipositors or egg-laying organs, and the internal seminal receptacle in which the spermatozoa received from a male are stored up, and serve to fertilise successive sets of eggs. In the queen-bee this store has been known to last for two or three seasons, while Lubbock tells of an aged queen-ant which laid fertile eggs thirteen years after the last union with a male.

Male and female insects are usually somewhat different in external appearance. The males are, on an average, more active, smaller, and more brightly coloured than the females. Extremes are seen in male and female Coccus insects (q.v.); in the sexes of Glow-worm (q.v.); in a few Butterflies (q.v.), such as *Orgyia*, where the female is wingless; or in the curious bee-parasites Strepsiptera, where the female virtually remains a grub. As some insects have an elaborate courtship, in which the females choose their mates, and as some males fight their rivals, there can be little doubt that Sexual Selection (q.v.) has accelerated the evolution at once of beauty and strength, while natural selection (see DARWINIAN THEORY, EVOLUTION) may have retarded the evolution of gay colouring in the females to whom conspicuousness is especially disadvantageous in parentage. Neither position is inconsistent with that which regards the characters of the two sexes as natural and necessary expressions of their respectively dominant constitutions. See Darwin, *Descent of Man*; Wallace, *Darwinism*; Geddes and Thomson, *Evolution of Sex*.

Peculiarities in Reproduction.—(a) Virgin birth or parthenogenesis occurs normally, for a variable number of generations, in two butterflies and a beetle, some Coccus insects and Aphides, certain saw-flies and gall-wasps; it occurs casually in the silk-moth and about a dozen other Lepidoptera, partially or voluntarily in the drone-bearing of hive-bees, seasonally in Aphides (q.v.), and in larval life in some midges (e.g. Chironomus). (b) Where parthenogenesis occurs for a period and is thereafter followed by ordinary sexual reproduction, as in Aphides, we have to deal with one of the many forms of Alternation of Generations (q.v.). (c) A few insects are exceptional in being viviparous, bringing forth their young alive. This is again illustrated by Aphides, and also by a few flies, by the little bee-parasites Strepsiptera, and by some beetles. (d) Many insects are exceedingly prolific—e.g. aphid, silk-moth, and queen-bee. A climax

is reached in the queen-termite which for a time goes on laying thousands of eggs 'at the rate of about sixty per minute!'

Development of the Egg.—The ovum of insects, as it passes down the ovarian tubes, is enclosed in a firm chitinous envelope, with a minute aperture or micropyle (sometimes with more than one), through which a male element or spermatozoon penetrates before the ovum leaves the mother. The segmentation which follows fertilisation is for the most part peripheral (centrolecithal; see EMBRYOLOGY), while the centre of the egg is occupied by a relatively passive yolk with scattered nuclei. The result of segmentation is a sphere or ellipsoid of cells enclosing the core of yolk, and on the ventral surface of the sphere or ellipsoid the embryo

Fig. 7.—Ventral aspect of five stages in the development of the Water-beetle, *Hydrophilus* (after Heider): The anterior end is uppermost. *a*, head lobes; *b*, the last of the body-segments, which are seen becoming more marked throughout the series; round about the embryonic area the amniotic folds develop.

begins to be mapped out. This development we cannot here follow, but it is important to notice one unique fact, that the embryo is arched over by a double fold, constituting the internal amniotic and outer serous membranes, so called from their resemblance to the similar enswathing envelopes in the embryos of higher vertebrates. See Lang's *Lehrbuch der Vergl. Anatomie* (vol. ii. Jena, 1889), where a summary of results and literature will be found.

Metamorphosis.—(1) In the lowest insects—the old-fashioned, wingless Thysanura and Collembola—the young form which emerges from the egg-shell is in all respects a miniature adult. Without striking change, by growth and moultings, it becomes an adult. From this entire absence of metamorphosis we readily pass to the life-histories of cockroaches and locusts, of lice and most bugs, where the newly-hatched young are very like the parents. The reproductive organs are, of course, undeveloped, and there are no wings, but the latter are not attained even by the adult lice. All the above forms may be called *ametabolic*—i.e. without marked change or metamorphosis.

(2) In Cicadas there is a slight but most instructive difference between larvæ and adults. The full-grown insects live among herbage, the young live in the ground, and with this diversity of habit is associated at least this much difference in structure, that the anterior legs of the larva are adapted for burrowing. Furthermore, the larval life ends in a quiescent stage, or, in other words, the adult form is attained after a period of pupation. But the story becomes more complex when we pass to the Dragon-fly (q.v.), the Ephemera (q.v.), and their relatives, where the metamorphosis is slightly greater, inasmuch as the larvæ are aquatic, with closed respiratory apertures, and with tracheal gills, while the adults are winged and aerial, and breathe by open tracheæ. Such insects are said to have an incomplete metamorphosis, and are called *hemimetabolic*.

(3) Very different, however, is the life-history of

all the other insects, such as butterflies and beetles, flies and bees. From the egg-shell there emerges a larva (maggot, grub, or caterpillar), which lives a life of its own, growing and resting and moulting, often very active in its movements and voracious in its diet. Having accumulated a rich store of reserve food in its fat-body, the larva becomes for a longer time more or less quiescent, becomes in fact a pupa, nymph, or chrysalis. In this stage, often within the shelter of a spun cocoon, great transformations occur: wings bud out, appendages of the adult pattern appear, reconstruction and centralisation of organs are effected; and finally, out of the pupal husk there emerges an imago or miniature fully-formed insect. These have a complete metamorphosis, and are called *holometabolic*.

The larvæ of these higher insects with complete metamorphosis differ greatly in different orders. Thus, the 'maggots' of flies (without distinct head, feelers, ocelli, &c.) are distinguished from the 'grubs' of bees (with distinct head), and both from the caterpillars of butterflies, &c., which have limbs as well as head. The limbless maggots and grubs are degenerate, the caterpillar is the more normal type. It is technically called an 'eruciform larva,' in contrast to that of most *Ametabola* and *Hemimetabola*—the 'campodeiform larva,' which is not even worm-like, but like one of the lowly *Thysanuran* insects (*Campodea*), with the regions of the body well defined, with biting mouth-parts, with locomotor thoracic limbs, &c.

But beyond distinguishing the above two great types of larva (campodeiform and eruciform), and also the maggot, grub, and caterpillar forms of the latter, little more is possible in this general survey, for the larvæ vary enormously, according to their own mode of life—parasitic or roving, aquatic or terrestrial, carnivorous or herbivorous—and according to the peculiarities of the adult forms. We must note, however, the changes in connection with the mouth-organs, especially as these form part of the basis of classification. 'The mouth-parts may be similar in all stages of life, and then are either adapted for biting (*Menognatha*—i.e. jaws persistent) or for sucking (*Menorhyncha*—i.e. proboscis persistent); or else they are adapted in the larva for biting, in the adult for sucking, the change commencing in the pupa, and rarely affecting the larval stage (*Metagnatha*—i.e. jaws changed).' See Brauer's classification in Hatchett Jackson's edition of Rolleston's *Forms of Animal Life* (1888).

The Internal Metamorphosis.—One of the most interesting and difficult problems with regard to insects concerns the transition from the larval to the adult structure. In those forms which have no metamorphosis, or only an incomplete one, the organs of the larva develop continuously into those of the adult. It is far otherwise in the complete metamorphosis of the higher insects. There the internal changes are as marked as the external; in fact, there is a gradual reconstruction of organs during the later larval, and especially during the pupal stages. Most of the larval organs are absorbed by amoeboid cells, and their debris utilised in building up new structures. To a certain extent the development of new organs takes place by substitution; that is to say, parts of the larval organs which have not been specialised form the foundations of the adult structures. Of special importance is the appearance in the larva of 'imaginal discs' from which the wings, limbs, and epidermis of the imago or perfect insect arise. It must not, however, be supposed that the transition involves any abrupt change; the absorption, disappearance, and replacement of organs is gradual throughout. Yet almost the entire musculature, a great part of the tracheal system, the larger portion of the mid-gut, and many other parts of the larva disap-

pear and give place to the corresponding organs of the adult which are adapted to a new mode of life. In pursuing this study the reader will best begin with Martin Duncan's *Transformations of Insects*, Lubbock's *Origin and Metamorphoses of Insects* ('Nature' series, Lond.), and then pass to the cited work of Lang and the literature there quoted.

General Life.—Under this title we can do little more than mention some general aspects of the life of insects. (a) While insects are predominantly active animals, we find in contrasting the orders, or better still, the families, abundant illustration of the antithesis (to be read throughout the animal series) between activity and passivity. Thus might the female cochineal insect represent in its torpid, sessile life one extreme, and the exceedingly busy humble-bee another. (b) In the majority of cases the adult insect is short-lived, and dies within the year; an adult Ephemeroidea may be literally the fly of a day, but from this there are many gradations leading up to the rare cases of a queen-bee five years old, or an aged queen-ant of thirteen. The total length of life, including the metamorphoses, varies not a little with the climate of different countries and the weather of different years, and the life is prolonged in those insects which hibernate, passing the winter in a lethargic state hardly deserving the name of life (see *HIBERNATION, LIFE*; Weismann's essay on 'The Duration of Life' in *Heredity*, 1889; and another essay by Ray Lankester on *Comparative Longevity*, 1870). (c) It is worthy of notice that reproduction in a great number of insects of both sexes is shortly followed by the nemesis of death, love being in such cases at once the climax and end of life. (d) In connection with the influence of climate and seasons the occurrence of different or 'dimorphic' summer and winter broods in some Lepidoptera should be noticed (see Weismann, *Studies on the Theory of Descent*, Meldola's trans. Lond. 1880-82; and Scudder's *Butterflies*, New York, 1881). (e) Nor can we do more than refer to separate articles for description of the fascinating social life of many ants, bees, wasps, and termites. (f) The prolific multiplication of insects is kept within bounds by the limitations of food-supply and weather, by the warfare between insects of different kinds, by the appetite of higher animals, such as fish, frogs, ant-eaters, insectivores, and, above all, birds. As among other animals, we find among insects abundant illustration of peculiarities which have for their result at least the protection of their possessors. The leaf-insects, walking-sticks, moss-insects, humming-bird moths, scale-insects, &c. are striking examples of a protective mimicry in form and colouring which is illustrated in great variety and frequency throughout the class. Many larvæ, as well as adults, show especially in colour a sympathetic relation to their environment, while others, such as Caddis-flies (q.v.), are masked by the external coverings with which they clothe themselves. Many insects are saved by their hard skins, by their disgusting odour or taste, by their deterrent discharges of repulsive fluids, by their assumption of 'terrifying attitudes,' by the simulation of death, or by active resistance with their manifold weapons. See *MIMICRY*; and Wallace's *Darwinism* (1889) and literature there cited.

Classification.—There is as yet a want of unanimity about the classification of insects. A basis is usually found in the degree of metamorphosis, the characters of the wings, the structure of the mouth-organs, and the nature of the genital and excretory ducts. On many points future embryological research will shed light. All that we shall do here is to give the general grouping adopted by Brauer. See cited text-books of Hatchett Jackson and of Lang.

 1. *Dermaptera*.—Earwigs (A.).
 0. *Collembola* and *Thysanura*.—Primitive wingless insects.

Distribution in Space.—Insects are represented almost everywhere. The majority are indeed terrestrial and aerial, and especially at home in warm and temperate countries, but in the Arctic regions and in hot springs, at great heights above the snow-line and in underground caves, and most surprisingly even in the sea there are insect inhabitants. The *Challenger* explorers found one or more species of the genus *Halobates* (among the Hemiptera) which seemed to be quite pelagic. The limits of distribution are in great part those of climate and of the requisite food, for insects have great possibilities of dispersal, not only in their often extensive flight and liability to be swept along by winds, but through the conveyance of the dormant eggs or even grubs from one shore to another within floating logs. Thus, tropical insects are brought on floating logwood from across the Atlantic, while locusts have been known to fly or to be blown in safety across more than 300 miles of sea. See GEOGRAPHICAL DISTRIBUTION, and works there cited.

History.—Insects must have appeared in comparatively early times, for a cockroach-like wing has been found even in Silurian strata. Primitive dragon-flies and also lace-flies (*Neuroptera*) occur in the Devonian, cockroaches and walking-sticks (*Orthoptera*) in the Carboniferous rocks. There seems much reason to believe that the Palæozoic insects were mostly generalised, 'synthetic' types, prophetic of, rather than referable to, our modern orders. In the Trias *Orthoptera* abound; the first distinct beetles appear in the Lias, where other higher insects with complete metamorphosis also occur. See especially Seudder in Zittel's *Palæontologie* (1885).

Fig. 8.—*Campopoda staphylinus* (after Lubbock), one of the primitive wingless insects.

Pedigree.—As to their genealogy, suffice it to say that the wingless *Collembola* and *Thysanura*, at the base of the insect series, doubtless represent primitive forms; these lead us back to some of the less specialised myriopods, and these again to *Peripatus* (q.v.), the sole surviving genus of the ancestral Prototracheata. *Peripatus* links the air-breathing Arthropods to the ringed worms or Annelids, uniting, for instance, in its structure the tracheæ of an insect and the kidneys or nephridia of a worm. See Aubeury's

Origin, &c., of Insects, and then the papers of Brauer, Emery, Packard, &c., cited by Hatchett Jackson.

Economic Import.—Insects come into contact or collision with human interests in a great variety of ways. As far as they are concerned, the struggle between man and animals is by no means over. Strong in numbers, many of them are directly or indirectly injurious to man and his property to an extent which frequently affects the prosperity of a nation. Direct injuries to man's person are familiarly illustrated in the parasitism of fleas, lice, and other more or less intimate 'boarders,' but these are less important than the share the mosquito seems to have in the loathsome disease *Elephantiasis arabum*. The annoyance of midges is patent, but we feel the delicacy of the threads in life's web when we remember that the house-fly may disseminate the germs of bacterial disease. Personal injuries, however, are dwarfed when we think of those done to property, and especially to crops and herds, by voracious or by parasitic insects. Clothes-moth and furniture-borer, vine-insect and Colorado beetle, the bot-flies which attack sheep, cattle, and horses are familiar illustrations of formidable pests. It should also be noted how the hostile insects which infest forest trees and vegetation generally may occasion changes which have far-off effects on the fauna, scenery, and even climate of a country-side. In connection with injurious insects reference should be made to such articles as APHIS, BOT, CORN INSECTS, HESSIAN FLY, LOCUST, PHYLLXERA, TSETSE, WEEVIL, &c.; to the well-known and inimitable *Introduction to Entomology*, by Kirby and Spence; to the admirable works of Miss Ormerod; and to the researches of Riley, Packard, and others, in the *Bulletins of the United States Entomological Commission*. From either of the last-named sources a guide to the vast literature of this important department of entomology may be obtained.

As to the other side of the account, we cannot ignore our indebtedness to hive-bee and silk-moth, to cochineal and lac insects, which furnish us with their unique and valuable products. Others again are indispensable and indefatigable scavengers; many wage effective war upon their injurious kindred; while a few, such as locusts and some larvæ, are even used as food. All these benefits, however, seem small in the light of the great fact that the majority of plants are dependent upon insects, as the unconscious bearers of the pollen essential to the normal cross-fertilisation of flowers.

Plants and Insects.—Referring to the article FLOWER for a statement of the importance of insects in the cross-fertilisation of flowers, we are safe in saying that neither the flowers nor their constant visitors can be understood apart. Many insects, however, injure plants without any compensating benefit, and in this connection must be noted the frequent occurrence of protective structures in plants, which help to dismiss hostile intruders. On the other hand, there are numerous cases in which plants and insects (especially ants) form a mutual partnership. Such 'myrmecophilous' plants are saved by their bodyguard of ants from unwelcome visitors, and the benefit is sometimes returned (to speak metaphorically) by the growth of special shelters or 'domatia,' tenanted by the partner-insects. See GALLS, INSECTIVOROUS PLANTS, and the literature cited at FLOWER; also Kerner's *Flowers and their Unbidden Guests* (trans. Lond. 1878); and for references to the works of Delpino, Belt, Huth, &c., on 'myrmecophilous plants,' see Schimper's *Wechselbeziehung zwischen Pflanzen und Ameisen* (1888).

History of the Study of Insects (Entomology).—Insects had their due place in Aristotle's zoological

system, and since thoughtful observation began have been studied with much constancy. Malpighi (1623-94), whose name is perpetuated in connection with the excretory tubules, was the first to give a thorough description of an insect's (the silkworm's) anatomy. His contemporary Swammerdam got further in his investigation of insect metamorphoses. Ray (1623-78) and Linnaeus (1707-78) helped to infuse system and order into entomology, while the works of Réaumur (1683-1757) are classical models of carefulness. Rösel von Rosenhof, Bonnet, De Geer, Schaffer, Fabricius, and Lyonnet were among the illustrious entomologists of the 18th century. Cuvier (1769-1832) began the study of insects in early youth with an enthusiasm which he never lost, and was wont to trace to the precision gained in his dissections of insects no small part of his success as an anatomist. Savigny's comparison of the mouth-appendages of insects and other Arthropods was an important step on a path often pursued since; and among the great entomologists of the first half of the 19th century, all more or less influenced by Cuvier's example, were Latreille, Kirby, Dufour, Burmeister, Audouin, Blanchard, Lacordaire, and J. O. Westwood. But beyond this the embarrassment of illustrious names makes compressed history more and more difficult; suffice it to notice the recent progress made in the study of the minute structure—e.g. of the sense-organs of insects—in experimental analysis of the sensory powers, in elucidating a natural classification, in deciphering the history both of fossil forms and of the individual organism.

Kirby speaks enthusiastically of the wealth contained in a well-stored cabinet of insects, of the problems suggested by the study of their anatomy and physiology, but rightly urges that 'we must behold insects when full of life and activity, engaged in their several employments, practising their various arts, pursuing their amours, and preparing habitations for their progeny; we must notice the laying and kind of their eggs; their wonderful metamorphosis; their instincts, whether they be solitary or gregarious, and other miracles of their history.' Then we shall echo the words of Pliny, and of all entomologists: 'In these beings so minute, and as it were such nonentities, what wisdom is displayed, what power, what unfathomable perfection!'

As reference has been made throughout the article to special works, it will be enough here to mention some of the general books—(a) zoological text-books, such as those of Claus, Gegenbaur, Huxley, Lang, and Hatcher; Jackson's edition of Rolleston; (b) encyclopædia articles by Newport in Todd's *Cyclopædia of Anatomy and Physiology*, and McLachlan in *Encyclopædia Britannica*; (c) to the more popular natural histories—Cassell's (edited by Martin Duncan) and the Standard or Riverside (edited by J. S. Kingsley); (d) to general works—W. Kirby and W. Spence, *Introduction to Entomology* (4 vols. 1815-26; 1 vol. Lond. 1856); J. O. Westwood, *Classification of Insecta* (2 vols. 1839-40); V. Graber, *Die Insekten* (2 vols. 1877); W. F. Kirby, *Elementary Text-book of Entomology* (1885); Packard's *Entomology* (1898) and *Study of Insects* (1880); Howard's *Insect Book* (1901); the *Cambridge Natural History* (1895-99).

Insessores (Lat., 'perchers'), or PERCHING BIRDS, an order of birds called by Cuvier Passerine or 'sparrow-like.' The order includes more than half the known birds, but can hardly be defined, since the members are marked off rather by a combination of characters than by any uniqueness. The title is usually now replaced by that of *Passeriformes*. See BIRD.

Inspiration, in Christian theology, denotes the influence of God in the production of the Bible. The word itself is derived from the Vulgate translation of 2 Tim. iii. 16, *omnis scriptura divinitus inspirata*. It must not be supposed, however, that the claim of inspiration is confined to the Christian Scriptures. Orthodox Hindus regard the Vedas as of superhuman origin and absolutely infallible. The Parsees think that the Zend-Avesta was revealed to Zarathustra by Ormazd himself. The sacred texts of Babylonia were ascribed to the god Ea, who, according to Berosus, 'wrote a book in the beginning and gave it to men.' Moslems even to-day regard the Koran as an earthly copy of the original heavenly text which was made known to Mohammed in a trance by the angel of revelation. Moreover, it is not merely sacred books to which the term inspiration is applied. It is used by Plato in an equally divine sense of poetry. 'All good poets,' he says in the *Ion*, 'compose their beautiful poems not as works of art, but because they are inspired and possessed like the Corymbantian revellers, and they are not in their right mind when they are composing their beautiful strains . . . for the poet is a light and winged and airy thing and there is no invention in him until he has been inspired and is out of his senses. . . . God takes away the minds of the poets and uses them as his instruments.' Philo was the first to apply Plato's theory of inspiration to the Bible. 'A prophet,' he writes, 'gives forth nothing at all of his own, but acts as interpreter at the prompting of another. As long as he is under inspiration he is in ignorance, his reason departing from its place and yielding up the citadel of his soul, when the Divine Spirit enters it and strikes at the mechanism of his voice.' It was in reality, therefore, Greek thought under the influence of Plato that provided the categories in which the Christian doctrine of inspiration was stated, and what is known as verbal or plenary inspiration in its origin owes far more to the influence of Greek thought than to the statements of the Scriptures themselves.

The belief in *plenary* or *verbal* inspiration has been maintained from the earliest period of the church's history. Justin Martyr, for instance, says, 'We must not suppose that the language of the Bible proceeds from the writers but from the Divine Word which moves them.' These writers simply 'offered themselves in purity to the operation of the Divine Spirit that the Divine Power might of itself reveal to us the knowledge of mysteries, acting on just men as a plectrum on a harp or lyre.' In the same manner Athenagoras maintains that 'the Spirit uses the writers as its instruments just as a flute player might blow a flute.' Origen calls the books of Scripture 'the writings of the Holy Spirit.' While the early church was unanimous in assuming the fact of plenary inspiration, opinion was divided as to the manner in which inspiration worked. A few of the Fathers (e.g. Athenagoras and Tertullian) held that inspiration came while the writer was in a state of trance or ecstasy and that he himself was unconscious of what he wrote. Others, while denying the theory of a trance, maintained that the writers were the passive instruments of the Spirit and set down what was dictated to them word by word. A third school held that the mind of the writer himself was enlightened by the Spirit, and that this enlightenment extended even to the use of words. It was at the time of the Reformation that the theory of verbal inspiration reached its climax, in spite of the broader position which Luther himself took up. Gerhard, for instance, spoke of the writers of Scripture as 'amanuenses of God,' 'hands of Christ,' 'scribes and notaries of the Holy Spirit'; and the *Formula Consensus Helvetica* (1675) laid it down as the doctrine of the Reformed Church that 'the very vowel points and accents of the Hebrew

Bible were divinely inspired.' In modern times there have been three protagonists of the doctrine of verbal inspiration. Dean Burgon expressed his opinion in the famous dictum, 'Every chapter, every verse, every clause, what say I, every syllable of the Bible was divinely inspired.' Dr Charles Hodge stoutly contended that 'inspiration extended to all the contents of the several books, whether religious, scientific, or historical.' Dr Alfred Cave revived the trance theory, and said, 'Undoubtedly the state of trance in which the body is quieted and the soul aroused by Divine Inspiration plays a large part in the life of the Old Testament prophets.' Slowly but surely, however, the theory of plenary inspiration has been undermined by the advance of Biblical criticism. The discovery of the many discrepancies in the records (e.g. the hundreds of trifling divergencies in the synoptic narrative) is very difficult to reconcile with the belief in infallible inspiration. Our knowledge of the way in which many of the historical books (e.g. the Pentateuch and the Synoptic Gospels) were compiled, out of sources, is in flat contradiction to the assumption involved in the doctrine of plenary inspiration. The conflict between the statements of the Bible and the findings of modern science is extremely difficult to reconcile with any such hypothesis; added to which, there is the fact that the Bible itself never makes any such claim for itself since it is now certain that the A.V. rendering of 2 Tim. iii. 16—'All scripture is given by inspiration of God'—is a mistranslation. Moreover, it is now generally recognised that there are degrees of inspiration within the Bible itself, as Luther maintained, since some of the books are of much higher spiritual value than others; and Paul himself on some occasions (especially in 1 Cor. vii. 10, 12, 40) draws a clear distinction between advice which he gives on the authority of Christ and advice which is based upon his own judgment.

But while the theory of plenary inspiration is now generally abandoned, it does not follow at all that there is no inspiration in the Bible. The greatness of the Bible cannot be explained on the hypothesis that it was the unaided work of the human mind. We are still driven back upon the fundamental principle which is stated in 2 Peter i. 21, 'Men spake as they were moved by the Holy Spirit;' and Job xxxii. 8, 'There is a spirit in man, and the inspiration of the Almighty giveth them understanding.' But it is not easy to state with precision what exactly is implied in inspiration. One of the best modern statements on the subject is to be found in the definition given by Dr Driver: 'However difficult it may be to define Inspiration or to determine the mystery of its operation, those who use the term may be supposed to mean by it an influence which gave to those who received it a unique spiritual insight enabling them thereby without superseding or suppressing the human faculties, but rather using them as its instruments, to declare in different degrees and in accordance with the needs and circumstances of particular ages the mind and purpose of God.' It will be observed from this definition that (1) inspiration gives enlightenment or spiritual insight; (2) it works through the ordinary human faculties by enhancing their natural powers; (3) it operates in different degrees in different individuals; (4) the gift which it bestows is always related to the needs and circumstances of the age; (5) its final end and goal is to reveal the mind and purpose of God.

Another interesting definition with a wider sweep to it is given by Lord Balfour: 'Inspiration is that seen from the Divine side which we call discovery when seen from the human side. It is not inaccurate to say that every addition to knowledge, whether in the individual or in the community, whether scientific, ethical or theological, is due to

a co-operation between the human soul which assimilates and the Divine soul which inspires. . . . Inspiration is limited to no age, no country, and no time. . . . Are we to deny any measure of inspiration to the ethico-religious teaching of the great Oriental Reformers? Hardly, unless we are prepared to admit that men gather grapes from thorns and figs from thistles.'

If we take the wider view of inspiration suggested by Lord Balfour, the question at once arises, Why do we claim unique inspiration for the Bible? Why do we regard the Bible as more inspired than the Vedas, or the Analects of Confucius, or the Zend-Avesta? The answer may be given in the words of Robertson Smith: 'If I am asked why I receive the Scripture as the Word of God, and as the only perfect rule of life and faith, I answer with all the fathers of the Protestant Church, "Because the Bible is the only record of the redeeming love of God, because in the Bible alone I find God drawing near to man in Christ Jesus, and declaring to us in Him His will for our salvation. And this record I know to be true by the witness of His Spirit in my heart, whereby I am assured that none other but God Himself is able to speak such words to my soul."' In other terms, it is the character of the contents of the book that determines the degree of inspiration that lies behind it. It is the uniqueness of the revelation contained in the Bible that justifies us in claiming a unique inspiration for its writers. The measure of the difference between the revelation of God in the Bible and the revelation found in other sacred writings is the measure of the superiority of the inspiration in the Christian Scriptures.

Peake, *The Bible* (1913), pp. 378-407. For the older view see books by Cave, Hodge, and Dean Burgon. For modern statements see also Bruce, *The Kingdom of God* (1888); Fairbairn, *Christ in Modern Theology* (1893).

Insterburg, a town of East Prussia, on the river Angerap, 55 miles E. of Königsberg, had its origin in a castle of the Teutonic knights, built in the 14th century. It has important manufactures—agricultural machinery, hemp, cement, iron, beer, &c. Pop. 38,000.

Instinct, the constitutional basis of the so-called instinctive activities which occupy an area—on the inclined plane of animal behaviour—between reflex activities on the one hand and intelligent behaviour on the other. (a) Beginning at the foot, there are in all animals numerous effective activities which go on 'of themselves'—the automatic internal activities. (b) Then there are actions like sneezing, skin-twitching, eye-shutting, where an effective action follows an external stimulus, yet without conscious control (as we know) and without the higher nerve-centres (as experiment proves). (c) When numerous actions of this relatively simple sort are co-ordinated we have a compound reflex, such as chewing the cud.

(A) Beginning again at the top end, we recognise the *rational* activities of the higher reaches of human conduct, which involve *conceptual* inference. (B) Below this high level we have many cases where the behaviour of the man or the animal shows effective adjustment to novel conditions, involving a *perceptual* inference, and we call this *intelligent*. (C) But behaviour which originally required intelligent control may become habitual. Lloyd Morgan says: 'A habit is a more or less definite mode of procedure or kind of behaviour which has been acquired by the individual, and has become, so to speak, stereotyped through repetition.' Our point now is this, that instinctive activities occupy the area between compound reflex actions and habitual

intelligent actions, and yet are quite different from either.

Definitions.—We are not concerned here with the general questions suggested by such descriptions of instinct as refer it to 'immediate impressions from the First Mover or from the divine energy acting in the creature,' nor is it necessary to discuss those which make the term include all the adaptive actions of animals in sharp contrast to the intelligence of man. Some others, however, are more to the point. Thus, Hartmann defines instinct as 'action taken in pursuance of an end, without conscious perception of what the end is.' Spencer calls instinct 'a kind of organised memory;' Samuel Butler says 'instinct is inherited memory;' J. J. Murphy describes it as 'the sum of inherited habits.' According to Eimer, 'instinct is inherited capability, and especially inherited habit; or more exactly, instinct is the inherited power of acting habitually and without deliberation in a purposeful, intelligent fashion, under the influence of internal stimuli, with or without others from without.' According to Romanes, 'instinct is reflex action into which there is imported the element of consciousness. The term is therefore a generic one, comprising all those faculties of mind which are concerned in conscious and adaptive action, antecedent to individual experience, without necessary knowledge of the relation between means employed and ends attained, but similarly performed under similar and frequently recurring circumstances by all the individuals of the same species.'

Since a definition should aim at formulating the facts and avoiding speculative interpretation, and since it implies an unproved hypothesis to define instinct as 'inherited habit,' we pass to the more scientific, because more strictly descriptive, definition given by Professor Lloyd Morgan in his authoritative work *Habit and Instinct* (1896). From the biological point of view instincts are congenital, adaptive, and co-ordinated activities of relative complexity, and involving the behaviour of the organism as a whole. They are not characteristic of individuals as such, but are similarly performed by all like members of the same more or less restricted group, under circumstances which are either of frequent recurrence or are vitally essential to the continuance of the race. While they are, broadly speaking, constant in character, they are subject to variation analogous to that found in organic structure. They are often periodic in development and serial in character. They are to be distinguished from habits which owe their definiteness to individual acquisition and the repetition of individual performance.

Examples.—Instinctive actions are usually perfect from the first and independent of individual experience. Thus, the butterfly makes the remarkable transition from caterpillar to adult habits without hesitation or failure; the bee rifles flowers on its first flight; and the chick in the first few hours of its open-air life makes successful darts at flies. In other cases, however, practice appears to help, as in the nest-building activities of birds. Nor are instincts always sufficiently perfect, for ants store beads instead of grains, and mistake cow-wheat seeds for their own cocoons; flower-visiting insects also patronise bright-coloured wall-paper; and the lemmings in their instinct for going right ahead will swim straight out to sea. Marvellous are the instincts exhibited by social animals such as ants and beavers, by insects which provide elaborately for young which they never survive to behold, and in the nesting and migration of our common birds. Less pleasant, in fact almost devilish in ingenuity, is the instinct of the Spheæ wasps, which provide fresh meat for their future larvæ by storing spiders, insects, and caterpillars

which they have stung in their chief nerve-centres, with the result that the victims are not killed outright, but only paralysed.

Origin of instincts.—There are several theories as to the origin of instinctive activities. (1) They may represent the gradual co-ordination and refinement of reflex actions, unintelligent to start with. (2) They may arise from habits, which were originally controlled and intelligent, becoming by repetition and inheritance automatic. A habit is an individually acquired routine of behaviour, which by frequent repetition ceases to require attention or control. (3) They may be self-expressions of the organism on a line of their own, neither of the nature of compound reflex actions nor of the nature of 'lapsed intelligence,' but *sui generis*, advancing by germinal variations and winnowed by natural selection. It goes without saying that instinctive activities often have a spice of intelligence mixed up with them, and that they are capable of improvement by practice.

Institute, THE, in English law, is the mode of citation or reference to Chief-justice Coke's great work on English law, the name for the first part of which is *Coke upon Littleton* (see COKE).—*Institutes* is the name given to the elements of Roman or civil law. See LAW, JUSTINIAN.

Institute of France. See ACADEMY.

Instrumentation is the art of using, in composition, the various instruments and combinations of the Orchestra (q.v.).

Insulin, an extract first obtained by Dr F. G. Banting from 'islets' of cells in the pancreas of animals, and used successfully in some cases of Diabetes (q.v.). A dog whose pancreas is excised becomes diabetic. The secretion of the islets enables the body to make use of sugar in the blood. See GLANDS.

Insurance is a contract under which one party, called the Insurer, or Assurer, agrees, in consideration of a sum of money called the Premium, to pay a larger sum of money to another party, called the Insured, or Assured, on the happening of a designated contingency, through which the Assured would otherwise suffer a loss. Insurance has sometimes been said to be akin to gambling, but it is really the converse. The gambler seeks excitement and gain by the artificial manufacture of hazardous speculations. The prudent man resorts to insurance in order to secure peace of mind and immunity from the loss which might arise from contingencies beyond his control. The gambler creates or exaggerates risks; the insurance office equalises them.

The origin of insurance is lost in antiquity. At a very early period merchants insured their vessels and goods against the perils of the seas, and prob-

ably *marine insurance* was the first description to come into existence. From insuring ships and merchandise, the step was not a long one to insure for the voyage the life of the captain, on whom so much depended; and we therefore soon find traces of such contracts, the insurance frequently providing for the sum assured to be paid, not only in the event of the death of the captain, but also in the event of his capture by pirates, or by the king's enemies. Moreover, the merchant in those early days frequently accompanied the vessel in which his goods were shipped. Possibly he had obtained the goods on credit, on condition of paying double their cost should he return safely, and the creditor would thereupon insure the life of the merchant for that particular voyage. *Life insurance* proving in this connection very convenient, it gradually was resorted to in other business transactions, and ultimately came to be sought as a means of family provision.

Owing to certain scandals which arose in the middle of the 18th century, by reason of unrestricted gambling, legislation was passed in 1774 regulating insurances upon lives and prohibiting all such insurances, except in cases where the persons insuring have an interest in the life or death of the persons insured; the passing of this act marked an important landmark in the history of insurance.

The first evidence of *fire insurance* is to be found in connection with the Anglo-Saxon guilds, although probably it also was a development of marine insurance. The reader will find full information on the historical aspect of the subject in the various articles in Walford's *Insurance Encyclopedia*, and in an essay on the 'History of Life Assurance in the United Kingdom,' by the same author, in the *Journal of the Institute of Actuaries* (vols. xxv. and xxvi.).

Life Insurance.—The earliest life annuity bond which has been preserved was issued by the town of Tournai, southern provinces of Holland, in November 1228. It was granted by the provosts, jurors, aldermen, electors, mayor, and the entire commune of Tournai, and provided that, in default of payment of the annuity, they were to be excommunicated by the bishop. (For a French translation of this bond see the book mentioned lower down of the Dutch General Society for Life Assurances and Annuities.) The earliest life-assurance policy of which particulars have come down to us was made on 15th June 1533 at the 'Office of Insurance, within the Royal Exchange,' in London. Full details of this policy have been preserved, because it gave rise to the first authentic disputed claim. The policy was for £383, 6s. 8d., to be paid to Richard Martin in the event of William Gybbons dying within twelve months, and the policy was underwritten by thirteen different persons, who guaranteed sums of from £25 to £50 each. The premium was at the rate of £8 per cent. William Gybbons died on 28th May 1584, and the underwriters refused to pay because he had survived twelve months of twenty-eight days each. The Commissioners appointed to determine such cases held that the twelve months mentioned in the policy meant one full year, and they ordered the underwriters to pay. These appealed to the Court of Admiralty, which then had jurisdiction in such cases, and where in 1587 two judges upheld the decision of the Commissioners, so that eventually the underwriters had to pay. (For a full report of this case, taken from records in the British Museum, see the *Journal of the Institute of Actuaries*, vol. xvi. p. 419.)

In the 17th century many annuity societies were established, but on unsound principles, and they did not survive. The assurance company known

as the 'Hand-in-Hand' was started in 1696 under the name of the 'Amicable,' and in 1698 changed its name to the 'Hand-in-Hand'; but it undertook only fire insurance until 1836, when it entered also on life assurance. It was a purely mutual office, and proved highly successful, transacting a large and profitable business in both branches until 1903, when it amalgamated with the Commercial Union Assurance Company. The earliest known life-assurance company was established in 1699, and called the 'Society of Assurance for Widows and Orphans.' This was what now would be called an *assessment* company. It did not guarantee a definite sum assured, in consideration of a fixed periodical premium, but by its constitution it was to consist, when full, of 2000 members, who were to contribute 5s. each towards every death which occurred among the members; this contribution being designed to raise £500 on the death of each member, contingent on all members paying up. The next life-assurance institution started was the famous Amicable (a different company from the Amicable already mentioned). It was founded in 1705, and chartered by Queen Anne on 25th July 1706. Walford, in his *History of Life Assurance*, states that the plan of working was this: The number of members was to be 2000. Amongst the representatives of those who died in the first year one-sixth of the total contributions was to be divided; in the second year, if the full number of members was enrolled, £4000; in the third year, £6000; in the fourth, £8000; in the fifth and subsequent years, £10,000, with a proportionate reduction if the full number of members was not enrolled. The full contribution from the complete roll of members would be £12,000 per annum, and the surplus was to be accumulated. The Amicable lasted as an independent institution until 1866, when it was transferred to the Norwich Union Life Insurance Society, and its policies were finally merged in those of the Norwich Union on 30th June 1886. Various other life offices of the assessment order were started about the same time, but all except the Amicable disappeared on the bursting of the South Sea Bubble in 1720. On 29th April 1721 the London Assurance Corporation and the Royal Exchange Assurance Corporation, both of which had been chartered on 22d June 1720 for marine insurance, received additional powers, under which they were authorised to transact life and fire business. These twins both remain strong corporations at the present day, and are therefore the oldest surviving insurance offices in the world. The first life policy of the London Assurance Corporation was issued on 7th June 1721. The only other life office which we shall mention here is the Equitable, established in 1762, and prosperous still. Its history for now a century and a half has been the history of life assurance in England. Its affairs have been conducted by men eminent in the assurance profession, and to its cautiously directed enterprise in early days we are in great part indebted for the scientific soundness of the foundation on which the business of life assurance stands. Since the passing of the Life Assurance Companies Act in 1870, and still more so in virtue of the Assurance Companies Act, 1909, it has been possible to trace minutely the history; and to analyse the business, of every life company. Owing to amalgamations they are diminishing in number. At the time the Act of 1870 was passed there were about 130 in active operation, a number reduced to about 80 in 1925, and of these several write very little life business, their main activities being in other classes of business. Since the passing of the Act of 1870 a deposit of £20,000 must be made with the Court of Chancery before a company may commence life business, the deposit being made

permanent, and also compulsory on all existing companies, by the Act of 1909, and this has discouraged the formation of new offices. But although the number of companies has diminished, the volume of business has much increased. According to the returns of British ordinary life companies lodged with the Board of Trade in 1923, the premium income of the companies was £48,900,000, besides £2,600,000 received as consideration for annuities, and the interest on investments (less income-tax) amounted to £20,600,000, the accumulated life and annuity funds totalling £480,000,000. The Act of 1909 enables us to discriminate between business within the United Kingdom and business elsewhere. Of the above-mentioned premium income of the British companies, £45,600,000 was derived from policies within the United Kingdom, and the remainder from other policies. Also companies established outside the United Kingdom received £2,300,000 in premiums from British policy-holders, so that the total premium income due to policies within the United Kingdom was £47,900,000.

The elementary principles of life assurance are very simple. At first the rates of premium were fixed in a purely arbitrary manner, the result of guesswork, and no difference appears to have been made in respect of persons of different ages. But as experience was gathered it came to be seen that history repeats itself with great precision; that out of a given number of persons alive it can be approximately foretold from the results of the past how many will die within a given time; and it was further seen that the rate of mortality has a tendency to increase with the age of the lives observed—that is to say, for instance, that out of a thousand persons alive aged thirty fewer will die in a year than out of a thousand persons aged sixty. The first result of this advance in scientific knowledge was that a limit of age was fixed beyond which applicants were not admitted into the assurance offices, the Amicable refusing all aged forty-five and over; and a little later on the Equitable was started upon the still more scientific principle of charging rates varying according to age. This company departed from the existing practice of limiting the insurance to a single year of life and offered contracts covering the whole of life subject to level annual premiums, which were fixed at the outset, being paid throughout life; thus a person aged thirty might insure his life for £100 payable on his death occurring within one year for a single premium of £2, 4s. 6d., or alternatively for the same sum payable whenever he should die, in return for a premium of £3, 12s. 8d. payable annually throughout life. Early investigators tried to embody the results of experience in tabular form, and so produced forerunners of what are now known as mortality tables. These show, out of a given number born, how many complete each year of age, and by means of a properly constructed mortality table the rates of premium which should be charged for the assurance of lives can readily be calculated. John Graunt, F.R.S., a tradesman of Birchin Lane in the City of London, and captain in the City Train-bands, in the third edition (published in 1665) of his work *National and Political Observations*, gave a table showing how many, out of one hundred quick conceptions, are alive after six years, sixteen years, and so on decennially, until seventy-six years, and that none complete eighty years. This is the earliest mortality table on record; and, although for only every tenth year of age after age six, it is in modern form, and was used by Graunt in his investigations into vital statistics. About the time of Graunt, in the second half of the 17th century, several eminent men in Holland interested themselves in the subject, and Christian Huygens, the author of the first treatise ever

written on Probability, with his brother Lodewijk, applied Graunt's table to the solution of problems in life contingencies. On 22d May 1671 Johannes Hudde, burgomaster of Amsterdam, and a great mathematician, wrote to Christian Huygens that he was making calculations regarding the cost of annuities, basing them upon the registers of nominees in Amsterdam for annuities granted by the States-general in the years 1550-1560. There were 1495 such nominees, and on 18th August 1671 Hudde sent to Huygens a schedule giving the age of each life at the time of nomination, and the number of annual payments made before the annuity ceased by death. That schedule is to be found in the library of the university of Leyden, along with many other important papers of Huygens. From these statistics Hudde must have constructed a mortality table, because he calculated the values of annuities; but that mortality table does not seem to have been preserved, and we have no records of the methods of construction. Johan de Witt, Grand-pensionary of Holland, also in these early days applied scientific principles to calculations connected with annuities, which are analogous to those connected with assurances, his report on this matter having been distributed to the members of the States-general on 30th July 1671. His statistics were derived from the records of States-general annuity nominees of The Hague, and were of greater extent and a year or two later in date than those of Hudde, but they have not come down to us. We have, however, his mortality table, which, starting from age three, shows how many die in each half-year of age, until all have disappeared by age eighty. It is worthy of mention that the tables of Hudde and De Witt give almost identical annuity values.

The above very brief mention of the work done in Holland in the 17th century in connection with life annuities and assurance has been derived from a remarkable volume prepared by the executive of the Dutch General Society for Life Assurances and Annuities, of Damrak 74, Amsterdam. This book was printed in Dutch and in French in 1898. It was issued by the society practically for private circulation only, but copies are to be found in the libraries of the Institute of Actuaries, London, and the Faculty of Actuaries, Edinburgh, and, no doubt, elsewhere. The Dutch and French titles of the volume are not identical, but in English they may be rendered 'Materials to assist in the Compilation of the History of Life Assurances and Annuities in Holland. Collected and published by the Executive of the Dutch General Society for Life Assurances and Annuities.' The book consists of an edited selection of the weekly bulletins issued to the agents of the society. The first mortality table derived from general statistics was based upon observations in the city of Breslau, and was prepared by E. Halley, Astronomer-royal of England, and published in the *Philosophical Transactions* for January and March 1693. The first tables of premiums used by the Equitable Society were prepared from the mortality of the year 1741 by James Dodson, author of the *Mathematical Repository*, who was associated with Thomas Simpson, the well-known mathematician, in founding the society. Later on the Equitable adopted tables derived from the London bills of mortality, and later on still that known as the Northampton table, constructed by Dr Price from the statistics of the parish of All Saints, Northampton, during forty-six years from 1735 to 1780. These earliest mortality tables, derived from general statistics, were prepared from a record of the deaths alone; but it was subsequently discovered that this method gave erroneous results, and had a tendency

very much to exaggerate the rates of mortality. This method of compilation is only accurate if the population is in a stationary condition, and Dr Price, who was apparently aware of this fact, assumed that the population of Northampton was approximately stationary since the number of burials slightly exceeded the number of christenings; but in drawing this deduction he overlooked the large number of Baptists in the town whose records were only included in the returns of burials, and very substantial errors were introduced into his table. The correct method is to compare the numbers dying in successive age intervals with the population living in the same intervals, and this plan was followed by Dr Price in constructing his Swedish tables towards the close of the 18th century. On this principle also Joshua Milne, actuary of the Sun Life Office, constructed the famous Carlisle table, based upon the population of the parishes of St Mary and St Cuthbert, Carlisle, in 1780 and 1787, and the number of deaths that took place in each interval of ages in the same two parishes during nine years, beginning with 1779 and ending with 1787. The Carlisle table, which was published in 1815, formed for many years the basis on which were calculated the premiums and the reserves of a great many of the leading insurance companies. The records of the Equitable Society furnished materials for the construction of mortality tables from the experience of assured lives, and Griffith Davies, F.R.S., actuary to the Guardian Assurance Company, compiled the Equitable assurance table (1825) from data he derived from the annual addresses of the actuary of that office. Later on a committee of actuaries collected the experience of seventeen insurance companies, and the results were issued in 1843. The Institute of Actuaries collected the experience of twenty British companies, and gave it to the world in the volume of *Mortality Experience* in 1869; and the Institute of Actuaries and the Faculty of Actuaries in Scotland co-operated in taking out the mortality experience of assured lives and of annuity nominees, respectively, of sixty British companies for assurances and of forty-two companies for annuities, and, with the name of the *British Offices Tables*, published the results, with monetary tables, in a series of volumes, the first of which was issued in 1899. A further investigation into the mortality of annuitants relates to the experience of forty-nine British offices (and five others in respect of their British business only) during the period 1900-20; it was found that the vitality of annuitants had improved to a very marked extent since the previous investigation (1863-93) was made. In view of this, the new table, recommended by the compilers for future purchases of annuities, was based on the assumption that mortality rates in the future will continue to fall, and lower rates than those which obtained in 1900-20 are taken (*The Mortality of Annuity, 1900-1920*, by W. P. Elderton and H. J. P. Oakley, published on behalf of the Institute of Actuaries and the Faculty of Actuaries, 1924). The same feature was observed in the case of annuities issued by the National Debt Commissioners, and here, too, the mortality of the past generation was considered too heavy to be safely assumed for future transactions (*Mortality Experience of Government Life Annuity, 1900-1920*; Report by the Government Actuary and the Actuary to the National Debt Commissioners, published by H.M. Stationery Office). The need for fresh investigations at short intervals was clearly indicated, and the Institute of Actuaries and Faculty of Actuaries accordingly decided to make a continuous tabulation of the data of British offices in respect of both assured lives and annuitants in order to be able to test the experience periodically.

Owing to the disturbance due to the war no investigation into the mortality of assured lives had been considered practicable, and the next investigation covers the period commencing in 1924. Many individual companies have also taken out their mortality experience, and tables have been prepared from the experience of foreign companies by American and continental actuaries.

In the calculations of a life office the probabilities of life are combined with the interest of money. To take the simplest possible example: According to the Institute of Actuaries' mortality table, out of 1000 children aged ten, 956 will attain the age of twenty-one. Now, assuming that exactly 4 per cent. compound interest can be realised, the sum required to be invested at once in order to provide £100 at the end of eleven years is £64, 19s. 2d. If it be arranged that each of the 1000 children aged ten shall receive an endowment of £100 on coming of age, it is clear that 956 such endowments will ultimately become payable, and the amount now required to provide them is £62,100, 3s. 4d. In respect of each of the 1000 children, therefore, a sum of £62, 2s. must be paid down if he is to receive £100 on reaching his majority. This sum is called the present value of, or the single premium for, the endowment. An annuity consists of a series of endowments, the first payable at the end of one year, the second at the end of two years, and so on; and its present value, or the sum required to purchase it, is found by calculating the value of each of these endowments and adding the whole together. Similarly, if a sum of money is to be paid on the death of an individual, a calculation is made for the single premium to cover the risk of death in the first year; so also for the second year, for the third year, &c., to the utmost possible duration of human life; and the results are added together in order to find the single premium for an assurance on his life. For the annual premium an equation is made between the value of an annuity on the life and an assurance on the same life; and thus the annuity—in this case called the annual premium—equivalent to the single premium is ascertained. In order that such calculations may be made easily and simply various monetary tables are in the first place prepared, and the calculations, which would otherwise be so laborious as to be almost prohibitive, are thereby rendered very brief and easy. On principles similar to those adopted in such simple cases as are above indicated actuaries are able to solve many complicated problems. For instance, it is easy to ascertain what should be the premium for an assurance payable in the event of one person of a given age dying before another person of a different age; or many lives may be introduced with various orders of survivorship. The simpler questions of this nature may be solved directly from the mortality table and the subsidiary tables which are usually prepared from it; but when very complicated questions arise other processes must be resorted to. By the appropriate application of formulas of approximate summation; involving the use of the differential calculus or the calculus of finite differences, close accuracy in the solution of complicated questions can be secured. Many of these formulas, which, doubtless, are now familiar to mathematicians, were designed by actuaries for the solution of their own problems.

It has already been remarked that the rate of mortality increases with the age. The usual custom of insurance companies is, however, to charge a uniform premium throughout life, and it naturally follows that this premium must be in excess of that required for the mere assurance in the earlier years when the mortality is comparatively

light, so that that excess may be accumulated at interest, and become available in the later years of the policy when the rate of mortality is heavier, and when the uniform premium charged is no longer sufficient for the risk. In this respect life assurance differs from fire insurance. With fire insurance a reserve is required only for the unexpired portion of the time for which the premium has been paid, and to provide against fluctuations and contingencies. In life assurance a reserve is also required for these objects; but, in addition, a reserve is necessary, as above pointed out, on account of the increasing rate of mortality. Hence it follows that life companies transacting business by uniform premiums must accumulate large funds, which are not profit, but are absolutely necessary in order to meet prospective liabilities. This is clearly shown when a company, as sometimes happens, closes its door to new business, and determines simply to continue its existence in order to run off current contracts. For a time the funds will increase, but presently it will happen that the claims will absorb the whole of the premium and interest income. A little later on the claims will be in excess of such income, and the investments will have to be drawn upon, until when the last policy falls in the funds will be completely exhausted. In the early days of the Equitable Society, when it was uncertain what would really be required to cover the risk, much larger premiums than ultimately proved to be necessary were charged; and as there were no shareholders, the large surpluses which accumulated were distributed among the policy-holders. This system became so popular that when other companies were started at a later date, although the rates of mortality were much more accurately understood, an additional premium, over and above that required for the risk and for expenses, was deliberately charged, so as to provide a fund out of which bonuses might be paid to the policy-holders. It is now the universal custom of life offices to have a participating class of policy-holders, among whom the periodical surpluses are distributed. There are many ways in which these so-called profits are divided. Some companies make it a feature to return the surplus in cash, or as a reduction of the premium. Others treat the share of surplus belonging to the individual policy-holder as a single premium to provide an assurance on his life, in this connection called, a reversionary bonus; so that instead of paying away at once the money to the policy-holders, the sums assured under the policies are increased. Other companies combine these various methods, and give policy-holders their choice. With some companies the reversionary bonuses are large in the early days of a policy, and gradually diminish as time goes on. Others give comparatively small reversionary bonuses at the outset, these increasing with the lapse of time; and others again give practically uniform reversionary bonuses throughout the duration of the policy, the premiums in each case being appropriate to the schemes adopted. The systems being essentially so different, it is difficult to compare one company with another, and the intending policy-holder should judge for himself which system would best suit his own circumstances, and act accordingly.

Down to comparatively recent years practically the only policy issued by companies was the whole life insurance subject to annual premiums. Towards the end of the 19th century, however, a new form of contract was introduced, securing the payment of the sum assured (with or without bonuses) on attainment of a specified age or at earlier death, thus combining an endowment with a temporary insurance. These policies, known as 'endowment assurances,' have grown rapidly in popularity, and

now form the greater part of the business on the books of insurance companies.

The war threw very heavy burdens on insurance companies; and it is a great tribute to the methods by which their business had been built up, and to the stringency of their reserves, that they were enabled to pass through their trials without serious and lasting impairment. In the first place, very heavy losses were caused by premature claims among the younger policy-holders who died on active service. In the case of the majority of existing policies the contracts had been issued free of restrictions, and no extra premiums could be charged; in others, where this was not the case, the companies generously assisted their policy-holders by waiving their rights to an extra premium, or by charging one of nominal amount. In regard to new policies, however, substantial additional premiums had to be imposed, and the scale of these grew steadily during the war as the intensity of the fighting increased, until the issue of new policies to men of military age practically ceased. In the second place, the depreciation of stock exchange securities which had already set in before 1914, and which continued throughout the war, necessitated the drastic writing down of the assets of all insurance companies. Thirdly, for some years the greatly increased burden of income-tax more than counter-balanced the more favourable rates earned on new investments, and the net rate of interest earned on the total funds was little, if anything, in excess of that earned hitherto. After the armistice there was a great revival in business owing to the inadequacy of existing policies in view of the decreased purchasing power of the sovereign, and also to the large demand among men of military age who had been forced to postpone taking out policies until after demobilisation. It is not surprising, therefore, that nearly all the offices had to suspend, or materially reduce, their distribution of bonuses during the war; and it should be recorded with satisfaction that as company after company took the prudent course of passing its bonus, public opinion was in complete accord with the drastic action taken, and it may be said that the confidence of the general public in the stability of the system was fully indicated in the rapid expansion of business following the armistice. Later the values of securities tended to increase, and with the light rates of mortality and the somewhat smaller calls in respect of income-tax, offices were able to resume the distribution of bonuses; in some instances, indeed, the appreciation of securities enabled some compensation to be given to the older policies in respect of the bonuses lost during the war.

The Institute of Actuaries, founded in 1848, was incorporated by royal charter in 1884. Its journal, regularly published since 1850, contains a vast number of most important and useful original contributions on the theory and practice of life assurance. All the leading British actuaries have contributed, and almost every discovery of importance in actuarial science has first been published in its pages. By monthly meetings, at which papers are read and discussed, the Institute has also done much to promote the investigation and to disseminate the knowledge of life contingencies. In early days it initiated a system of examinations, and gave diplomas to students who satisfactorily passed them, so that the directors of insurance companies could know who were the men qualified for posts that might become vacant. Later on lectureships were added to train the students, and under the auspices of the Institute a text-book in two parts was published, dealing respectively with interest and annuities certain, and with life contingencies; the second of these remained the standard guide for students in all countries (it was published both in

English and in French) for upwards of quarter of a century. Recently revision was found desirable, mainly owing to the better mathematical equipment of actuarial students, and a new text-book on the subject of life contingencies was published in 1922. At the same time a new text-book on *Calculus and Probability* was issued, experience having shown that the ordinary mathematical treatises were not altogether suitable for the use of actuarial students, and the need for a book written with the special requirements of the actuary in view had become evident. The Faculty of Actuaries in Scotland does in that country what is done in England by the Institute of Actuaries, and co-operates with the Institute in actuarial research. It publishes regularly its valuable transactions, as do also several colonial and foreign actuarial societies.

The Life Assurance Companies Acts, 1870-72, were passed owing to the disastrous failure of two great companies, the Albert and the European. These acts were repealed in 1909, and the Assurance Companies Act, 1909, substituted, which brought within its scope not only life assurance companies, but also fire, accident, employers' liability, and bond investment companies. Under these acts all insurance companies have been required to register their accounts in specified form; and by the Acts of 1870 and 1909 life companies, and by the Act of 1909 also accident, employers' liability, and bond investment companies, must at periodical intervals give very full details relating to their actuarial valuations. The view taken by the British legislature has been that it is well to allow the companies to be managed by their own responsible officials, and that the government should not actively interfere, but that for the protection of the public full information should be available. The acts also have proved of great benefit by providing for the reconstruction instead of liquidation of life insurance companies. A third great advantage of the acts has been that reckless amalgamations have been rendered impossible. Now such full details of everything that is done in connection with an amalgamation must be published, that anything like extravagance or unjustifiable expenditure is almost impossible. The Board of Trade publish annually a return of the accounts and valuation statements which have to be deposited pursuant to the Act of 1909; the information relating to each company's life business is given in considerable detail, that relating to other classes of business in summary form; comparative figures aggregated from the returns of all companies for the year of review and each of the nine years preceding that of the return are also tabulated. Up-to-date information is also available from the annual supplements prepared by certain insurance and financial periodicals, that of the *Statist* is published in June of each year, and gives provisional figures—which do not usually differ appreciably from the complete figures subsequently published by the Board of Trade—relating to the business of the preceding year.

Industrial Insurance is the name given where life policies are of small amount, and secured by weekly, or at most monthly, premiums. The premiums vary from $\frac{1}{4}$ d. to 3d. or 6d. a week, and it is usual, instead of the premium being adjusted to the age, to adjust the sum assured; so that, while at all ages the premium is the same, the amount of the policy decreases with the age of the life at entry. An enormous industrial business is transacted in Great Britain, partly by insurance companies and partly by Collecting Friendly Societies (q.v.). The industrial companies of the United Kingdom had in 1922 a total premium income of £31,600,000, and received in interest £4,800,000. Arising out of certain criticisms of the system mainly directed to

the high proportion of premiums which were absorbed in expenses of management, a Departmental Committee was appointed in 1919, and the Industrial Assurance Act, passed in 1923, gave effect in the main to their recommendations. With few exceptions, the companies concerned were found to be in a satisfactory condition, but there were others which had not been run on sound lines, and the act laid down certain requirements designed to secure substantial improvement within a limited period. Subsequent returns indicate that by revised methods of administration many of the companies concerned have been able materially to reduce their expenses, and to strengthen their reserves accordingly.

Fire Insurance, Marine Insurance.—The contract of fire insurance is a contract purely of indemnity—i.e. the assured may not make a profit out of a fire, but is merely indemnified against loss sustained. Therefore it is not the cost of the goods at the time of purchase that is taken account of in settlement of a loss, but their value at the time of the fire. For instance, if a merchant have stored cotton for which he gave £1000, and if a fire occur when his stock would realise only £800 if placed upon the market, then £800 is the limit of the amount he can recover, although he may have been holding the cotton for an advance in prices. Again, if a householder have a claim upon a company, he can only recover in respect of the value of his furniture and effects, after allowing for the depreciation due to wear and tear—i.e. by the contract of insurance he is entitled only to be placed in the position which he occupied immediately before the fire, and not in one better. In this important respect fire insurance differs from life assurance, because in the case of a life policy, the amount of the interest of the assured is fixed at the time the policy is issued, and he may on the death of the life assured recover that full amount, although at the time of the death his interest may possibly have altogether ceased. The contract of fire insurance differs also in important respects from the marine insurance contract. In the latter, if goods are assured for less than their value, the policy-holder carries the risk himself for the amount uninsured. For instance, if a merchant have goods on a vessel to the value of £1000, and if he insure for £500, and if damage to the goods occur to the amount of £500, he can recover only £250, he being his own insurer for the difference between the value of the goods and the amount of the policy (for fuller information on Marine Insurance, see AVERAGE). In the case of the fire-insurance contract, however, the whole £500 could in such event be recovered from the company, unless in the exceptional case of an average clause having been inserted in the policy. By the average clause the insured is made his own insurer for whatever amount is not covered by fire policies, and it is sometimes inserted in policies covering large trade risks, and also in those covering goods stored in scattered warehouses. By the usual wording of fire policies, the company has the right to refuse a renewal premium, and here again there is a marked difference from a life policy, which is renewable at the option of the assured, but not of the assurer. A fire policy is not assignable without the consent of the office, which it is usual to give by the way of indorsement. Thus, if a merchant whose goods are covered by insurance sell the goods, the protection of the fire policy is not thereby transferred, but the purchaser must make his own arrangements. Thus, in the common occurrence of the purchase of a house, although the house may have been covered by a policy in the name of the vendor, the purchaser cannot recover under it without an indorsement having been placed

upon it transferring the insurance from the vendor to himself. The contract of fire insurance is personal between the insured and the office, and the insured can therefore recover only the amount of his own personal loss. Thus, for instance, unless so stated in the contract, the goods of a servant are not covered by the fire policy in the name of the master; and goods in the hands of an agent are not covered by a policy in the agent's name. As the wording of fire policies is very strictly construed by the courts of law, and as the offices for their own protection are often compelled to take their stand on the literal contract, though they seek to meet liberally every *bona-fide* claim, the policy-holder should be careful to see that his policy is in accordance with his wishes.

Prior to 1869 a special tax was imposed on fire-insurance companies, and the returns they were called upon to make furnished an accurate record of the amount of fire-insurance business transacted in the country. In 1869, however, the tax was repealed, and a stamp of one penny only on each policy was substituted. The result is that, except in the metropolis, where for the metropolitan fire-brigade, under act of parliament, a rate is paid by the companies in proportion to the amounts assured, it is impossible to say what is the total business of the country.

Fire offices may be distinguished broadly as tariff and non-tariff. The tariff are those which belong to the Fire Offices' Committee, an association formed for mutual protection, and, by the regulation of rates, to obviate destructive competition. The non-tariff offices are those which profess to estimate each risk on its merits, without fixing a minimum; but most frequently those offices which try this plan find it unsatisfactory, and subsequently join the tariff. Great Britain is eminently the country of successful fire offices, and several of the British companies are larger than any established in any other part of the world. Many of the British offices transact an enormous foreign business.

Accident Insurance generally provides for a sum payable in the event of death by accident, or for compensation, either by way of a lump sum or of a weekly allowance, in the event of injury or disablement from accident, or, often, from certain specified diseases. Since the passing of the various Employers' Liability Acts and Workmen's Compensation Acts, notably that of 1906, the insurance of employers against the liability imposed on them for accidents to their workmen has grown enormously. By an amending act passed in 1923 the scales of compensation were increased, and an interesting innovation, so far as Great Britain is concerned, is the provision for additional compensation where the deceased workman left dependent children. Since the passing of the act an agreement, on the lines recommended by a Departmental Committee which examined the subject in 1920, has been arrived at between the government and the companies transacting workmen's compensation insurance, under which the premiums charged are to be such that the 'loss ratio' is to be not less than 60 per cent. of the premiums in each of the years 1924, 1925, and 1926; thereafter the ratio may be increased to 62½ per cent. Another department which has grown to large proportions is the insurance of motorists, not only against accidents to themselves, but their liability for injuring other persons. A new form of accident risk which has now to be covered is that of aviation. This class of business is at present in its infancy, and there are few reliable statistics as to the rate of accidents in civilian flying on which to base premiums. A few insurance companies are prepared to issue policies combining life insurance with accident or

disability insurance, allowing in some contracts for the waiver of the premiums during serious and prolonged incapacity, and in others periodical payments or the earlier maturity of the policy on a permanent breakdown in health occurring. These forms of contract are better known on the other side of the Atlantic. A few of the very miscellaneous directions into which accident and casualty insurance, &c., has spread are burglary and larceny, profits and income, performance of contracts, chemists and druggists (against risks connected with the dispensing of drugs), growing crops (against hailstorms), school epidemics, public-house licenses, debentures and other securities, plate-glass, risks from steam-pipes and boilers, trustees and executors.

Fidelity Guarantee Insurance, to secure employers against fraud on the part of servants, was attempted in 1720, but the first special office, the Guarantee Society, was established in 1842. Since then this form of protection has been very widely sought.

In the *United States of America* the first life insurance society was established in Philadelphia, in 1759, and two others, in Philadelphia and New Jersey, were established before the close of the 18th century. More followed early in the 19th century, but it was not till between 1840 and 1850 that the movement began which has resulted in the enormous business now transacted. American insurance law differs in very many respects from that of Great Britain. The principles have been adopted of strict state supervision, and of a standard of solvency. In each of the states there is an officer charged with the duty of examining into the affairs of insurance companies, of making valuations, and of reporting the results of his investigations; and if the assets, which are carefully supervised, and must be invested in securities authorised by law, are not sufficient to meet the liabilities as legally estimated, the company is compelled to close its doors to new business. As each state of the Union legislates on insurance matters quite independently of all the others, considerable confusion has been produced. In different states different standards of solvency are set up, and it might quite well happen that in one state a company might be adjudged bankrupt, while in another the commissioner might on the same day give his certificate that it was in a position to meet all its engagements. Practically, however, these anomalies, beyond putting the companies to a great deal of trouble, do not cause much inconvenience, and the various states are gradually assimilating their regulations. Because of irregularities which took place in the management of some of the companies an inquiry was held by the State of New York, with the result that what are called the Armstrong laws were passed in 1906. These have since been repealed, and a new act was substituted in 1909. One principal feature of the American system of transacting business was the Tontine (q.v.) system, which grew to gigantic proportions until prohibited by the Armstrong laws of 1906. In England, in almost all cases, the surpluses are distributed among the policy-holders by way of immediate bonuses, but in America the great majority of policies were issued on the condition that profits were to accrue only if the life survived and if the policy were kept in force for the stipulated period. The effect of this condition is that when profits do vest, they are of course larger than if the policy-holders had received immediate bonuses. In former times not only were the profits placed in a Tontine, but the policies themselves were subject to a similar arrangement; so that unless the renewal premiums were punctually paid, the policies would lapse, and

all premiums paid would be forfeited, and the assured would derive no benefit from them.

In the *British Dominions* life assurance has also developed in a marvellous manner; and, considering the relative populations, Great Britain is left far behind. The Australasian colonies in particular are pre-eminent for the success of their insurance offices, the Australian Mutual Provident Society of Sydney being the largest, and giving as large bonuses as any company in the world; this result being due in part to good management, but principally to the high rate of interest, coupled with a low rate of income-tax, which invested funds yield at the Antipodes, and to the low rate of mortality prevailing. In Canada, besides Canadian companies, there are British and United States companies doing a large life insurance business. The Canadian insurance laws follow the model of those of the United States, but are not quite so restrictive.

While in Australasia insurance laws differ in various respects from those of the United Kingdom, yet they are still further removed from the regulations of the United States of America. There is no standard of solvency, and no government supervision in the ordinary sense of the word; but companies have to make returns somewhat on the British system, so that the public may have full information. In France, Germany, and Austria there are also large insurance companies, and very stringent and restrictive laws.

Government Insurance.—From an early period the British government has been accustomed to grant annuities on lives, the transactions being carried out by the National Debt Commissioners as a means of debt redemption. The annuity business having been very large and very successful, it was naturally thought that an insurance business providing for sums payable at death might with equal propriety be undertaken, and consequently, through the medium of the post-office, a life-assurance office was started on the 17th April 1865, but the results have been small, and have not answered expectations. Probably the reason for this comparative failure of the British life-assurance department is that no efforts are made to develop the business, and no commission is paid to agent.

New Zealand has also initiated a system of government insurance which commenced in 1874, but there the practice of private companies has been followed, and with eminent success. The New Zealand government also transacts insurance business in the accident and fire branches.

In Italy life assurance business has been since 1912 a government monopoly, and private companies are no longer permitted to engage in it; and, although their business has been thus destroyed, the companies did not receive any compensation.

Social Insurance.—Germany was the first country to adopt compulsory schemes of social insurance, and that on a large scale. The first bill was passed in 1883, and provided for the compulsory insurance of workmen against sickness. In 1884 a further act was passed providing compulsory insurance against accidents; and in 1889 a third bill became law under which the working classes on disablement from illness or accident, or on attaining old age, receive a pension. The scheme has been amended and extended from time to time and passed through a critical time during the war, but it is not practicable here within the space available to go into details. Other countries have followed, more or less closely, the lead of Germany; a useful summary of the various schemes will be found in *Working Men's Insurance in Europe*, by Lee K. Frankel and Miles M. Dawson.

Compulsory insurance against sickness com-

menced in the United Kingdom in July 1912, the National Insurance Act having been passed in the preceding December after prolonged discussion and considerable amendment during its passage to the statute book. Several amending acts have since been passed; these have been consolidated with the principal act by the National Health Insurance Act, 1924, all the earlier acts including the Act of 1911 being repealed thereby. The amending acts did not, however, alter the main structure of the scheme; the Act of 1913 removed certain difficulties which came to light soon after the scheme came into operation; the Act of 1918, which followed the exhaustive examination in 1916, by the Departmental Committee on Approved Society Finance and Administration under the chairmanship of Sir Gerald Ryan, Bt., made better financial provision for women's insurance—the contribution under the principal act having proved to be insufficient, set up new protective arrangements designed mainly to assist approved societies which are subject to unfavourable sickness experience, and swept away a number of administrative complications which had been found to interfere with the smooth working of the scheme; the Act of 1920 increased the rates of benefits and of contributions, those originally presented having become too small owing to the diminished purchasing power of the sovereign.

The scheme includes every employed person, male or female, aged between sixteen and seventy, whose remuneration, unless engaged in manual labour, does not exceed £250 (formerly £160) per annum; but for manual labourers no limit of income is fixed. The benefits receivable by insured persons are (a) Medical Benefit, being medical treatment including medicines; (b) Sickness Benefit, being a weekly payment of 15s. for a man, 12s. for a woman, commencing on the fourth day of incapacity and running for not more than twenty-six weeks, followed by Disablement Benefit at the rate of 7s. 6d. a week for the remainder of illness; both sickness and disablement benefits cease at age seventy when ordinarily a pension under the Old Age Pensions Act commences; (c) Maternity Benefit of 40s., payable on the confinement of the wife of an insured person, or on the confinement of an insured woman (whether married or single). At the commencement of the scheme a Sanatorium Benefit, securing treatment in sanatoria or elsewhere in cases of tuberculosis, formed part of the scheme, but this service was afterwards (1921) transferred to the local authorities. Medical benefit is administered by insurance committees constituted for every county and county borough who are in control of the panel of medical practitioners in their area; on this panel any practising doctor may enter subject to the conditions of service laid down. Differing from the systems operating on the Continent the administration of sickness, disablement, and maternity benefits has not been entrusted to a central government department or to municipal authorities, but is in the hands of 'approved societies'—that is, friendly societies whether existing before the commencement of the scheme or formed subsequently for the purpose. An insured person has complete freedom of choice as to the society he wishes to join as a member; there are many types of society, friendly societies which also provide private insurance apart from the benefits under the National Health Insurance scheme (some of these are local in operation, others cover the whole country by means of branches or agencies), trade unions, employers' provident funds, and approved societies run under the aegis of the great industrial assurance companies and collecting societies. Each society is a separate financial unit, and any surplus which is found to be disposable

on an actuarial valuation of its assets and liabilities which is made at quinquennial intervals, ensures to the benefit of the members of the society concerned for distribution in the shape of additional benefits. The central control of the approved societies and insurance committees and responsibility for the general working of the scheme was originally vested in four bodies of commissioners—one for each part of the United Kingdom—set up for the purpose with a joint committee, under the chairmanship of a member of the government, to co-ordinate the several bodies; in 1919 these bodies were superseded by the Minister of Health in the case of England and Wales, and by the Scottish Board of Health in the case of Scotland, and in March 1922 the Ministry of Labour for Northern Ireland assumed responsibility for the scheme in that country; since April 1922 the Irish Free State has continued the scheme of insurance practically unchanged, but there is now no direct link between the two systems.

The contributions, except in a few special cases, are 10d. a week for men, and 9d. a week for women; in Northern Ireland where medical benefit is not provided, the rate is 2d. less. In addition the exchequer defrays two-ninths of the expenditure of societies, &c., on benefits, and societies accordingly are responsible for seven-ninths only of the benefits out of their own funds. Of the above contributions the employer pays 5d. a week, and the insured person, 5d. if a man, 4d. if a woman; it is incumbent, however, on the employer to pay both his own and his employee's contribution in the first instance, but he may deduct the employee's portion from the wages at the time these are paid. The contributions are paid by means of special stamps, on sale at post-offices, and affixed to contribution cards, which are surrendered to the approved societies concerned at the end of each half-year.

At the end of 1918 the first valuations of approved societies were made, and the results disclosed were very satisfactory; with almost negligible exceptions surpluses were found amounting to over £17,000,000 (or over £1 per member). Of these £9,000,000 were distributed in the form of additional benefits; no less than 88 per cent. of the insured population were entitled to these bonuses. National Health Insurance, embracing some 10½ millions of working men and 4½ millions of working women, has thus become a definite feature of the social system of the country, and has reached a position of great financial strength; doubtless further changes will be found necessary from time to time to meet new conditions, and a royal commission was set up in 1924 with wide terms of reference to examine the working of the scheme and to consider whether any changes or extensions are desirable.

In 1912 a limited system of unemployment insurance was instituted for certain trades, which may be summarised briefly as building, construction of railways, docks, &c., shipbuilding, mechanical engineering, iron-founding, construction of vehicles and saw-milling. During the war munition workers were brought in, and in 1920 the scope of the scheme was widely extended, and with the exception of persons engaged in agriculture and in private domestic service, practically all persons insured under the health scheme are now included; the aggregate number of insured persons being about 12 millions. The scheme is administered centrally by the Ministry of Labour, and is entirely separate from National Health Insurance; this has led to considerable criticism in many quarters on the plea that there is needless duplication of machinery. Owing to the disturbance in trade since the war the strain on the unemployment fund has been very

heavy, and various amendments in the rates and conditions of benefit, and in the rates of contributions have been called for. Until more stable conditions obtain, the scheme cannot be put upon a permanent basis.

Superannuation Funds.—The advantages of insurance have of recent years been appreciated in connection with the provision of pensions for the superannuated officers and servants of local authorities, railway companies, and other large employers. Unless proper provision is made for the liabilities assumed, the burdens may ultimately become very oppressive; in the early years of a scheme the pension commitments are generally almost negligible, but as years go on they grow steadily, until eventually they often amount to as much as a quarter or a third of the salary roll. If, however, an adequate premium is set aside during the years of service, a substantial reserve can be accumulated, sufficient to provide the benefits which accrue on retirement. The schemes in operation are very varied, and it will suffice to give in outline the provisions of the Local Government and other Officers' Superannuation Act, 1922, which can be adopted by any local authority in Great Britain. A contribution of 10 per cent. of salary is payable in respect of all officers, one-half of which is deducted from the pay of the officer, and the balance is provided by the authority. These contributions are invested during service, and together with accumulated interest form the fund out of which pensions are payable. If an officer breaks down in health after not less than ten years' service, he is awarded a pension of one-sixtieth of the average salary earned in the preceding five years for each year of service. On attainment of age sixty-five or on the completion of forty years' service but not earlier than age sixty, he may retire irrespective of the state of his health on a pension of one-sixtieth of the average salary (calculated as above) for each year of service, subject to a maximum of 40ths. In the event of an officer dying before retirement, his contributions are returned with interest.

In the case of the smaller employer the number of employees is often insufficient to permit of the successful working of a scheme on lines similar to those indicated above; and in these circumstances it is appropriate for the employer to reinsure his liabilities for pensions with an insurance office, many of which are prepared to issue deferred annuity contracts in return for appropriate annual premiums payable so long as the person remains in the service of the firm.

Intaglio (Ital., 'cutting in'), a term in art, the opposite of relief, means the representation of a subject by hollowing it out in a gem or other substance, so that an impression taken from the engraving presents the appearance of a bas-relief. See GEM.

Integral Calculus. See CALCULUS.

Intellect. See PSYCHOLOGY.

Intemperance. See ALCOHOLISM, DELIRIUM TREMENS, INEBRIATES, INTOXICATION; also TEMPERANCE.

Intendant, the name given in France before the Revolution to the overseer of a province. Under the complete system of centralisation established by Richelieu these intendants became the mere organs of the royal minister. The National Assembly, in 1789, established in each department an elective administration. Napoleon virtually restored the intendants, but exchanged the hated name for that of *Préfets* (q.v.). Intendant is the name of the person in charge of an estate, and there are *intendants militaires*, *intendants de la marine*, &c.

Intercalary (Lat. *intercalaris*, 'for insertion'), an epithet applied to those months or days which

were occasionally inserted in the calendar to make it correspond with the solar year. See CALENDAR.

Intercommuning, LETTERS OF, an ancient writ issued by the Scottish Privy-council warning persons not to harbour rebels.

Interdict, an ecclesiastical censure or penalty in the Roman Catholic Church, consisting in the withdrawal of the administration of certain sacraments, of the celebration of public worship, and of the solemn burial-service. Interdicts are of three kinds—*local*, which affect a particular place, and thus comprehend all, without distinction, who reside therein; *personal*, which only affect a person or persons, and which reach this person or persons, and these alone, no matter where found; and *mixed*, which affect both a place and its inhabitants, so that the latter would be bound by the interdict even outside of its purely local limits. The principle on which this ecclesiastical penalty is founded may be traced in the early discipline of public penance, by which penitents were for a time debarred from the sacraments, and from the privilege of presence at the celebration of the eucharist; but it was only in the mediæval period that, owing to circumstances elsewhere explained (see EXCOMMUNICATION), it came into use as an ordinary church censure in the then frequent conflicts of the ecclesiastical and civil power. It was designed to awaken the national conscience to the nature of the crime, by including all alike in the penalty with which it was visited. Remarkable interdicts were those laid upon England (for the murder of Becket) in 1171, and on Scotland in 1180 by Pope Alexander III.; on Poland by Gregory VII., on occasion of the murder of Stanislaus at the altar; by Innocent III. on France, under Philippe Auguste, in 1200; and on England under John in 1208. The description of England under the last-named interdict, as detailed by some of the contemporary chroniclers, presents a strangely striking picture of the condition of the public mind, which it is difficult with our modern ideas fully to realise or to understand. It would be a great mistake, however, to suppose that during the continuance of an interdict the people were *entirely* destitute of spiritual assistance. The interdict mainly regarded the *solemnities* of public worship; it was permitted to administer baptism, confirmation, and the eucharist in all cases of urgency; to confess and absolve all who were not personally the guilty participants in the crime which the interdict was meant to punish; to celebrate marriage, but without the solemnities; and to confer orders in cases of necessity. And under the popes Gregory IX., Innocent III. and IV., and Boniface VIII. still further mitigations of its rigour were introduced, one of which was the removal of the interdict and restoration of public worship on certain great festivals, especially Christmas, Easter, Pentecost, Assumption, and All Souls. The Council of Basel enacted very stringent rules as to the use of this penalty, and in later times the general interdict has been entirely disused, although occasionally, in very special circumstances, and to mark the horror of the church for some enormous crime, instances are still recorded in which a particular place or church has been visited with the penalty of a local interdict.

Interdict, in Scots law, is an order issued by the court to stop or prohibit a person from doing a specified illegal or wrongful act. The party applying for it must have both title and interest to object to the act complained of—i.e. he must be more than a mere stranger. The principles on which it is granted in Scotland are substantially the same as those in which the parallel Writ of Injunction (q.v.) is granted by the English court.—For *Interdiction*, see FACILITY.

Interest is the consideration paid for the use of money. The interest of £100 for one year is called the rate *per cent.*; the money lent, the principal; and the sum of any principal and its interest, the amount. The current or market rate of interest varies from a variety of causes, the chief of which are the relation existing between the accumulation of money and the demands of borrowers, the prevailing rate of profits on trade, and the security and duration of the loan. In Great Britain the price of the public funds indicates the interest obtainable for a permanent loan with no risk of loss, while the 'bank rate'—i.e. the minimum rate at which the Bank of England will discount bills—represents the interest for temporary loans with less undoubted security. In the former case, as with fixed annuities, the nominal rate of interest never varies; but the real return to the investor depends on the price he has to pay for the capital. Thus, if the price of 2½ per cent. consols be 91½, the actual return will be 3 per cent.

Interest is computed on either of two principles. **SIMPLE INTEREST** is charged on the principal alone for any length of time. The computation of simple interest is easy, resolving itself into a mere question of proportion: thus, having given the interest on £100 for 1 year, to find the interest on any other sum for any period. Various ingenious devices are made use of to save labour in these calculations, especially by bankers, and are given in most handbooks. **COMPOUND INTEREST** is the charge made where—the interest not being paid when due—it is added to the principal, forming the amount upon which the subsequent year's interest is computed. The rules for most readily making computations by compound interest can only be effectively expressed algebraically, and, using i to represent the interest of £1 for one year, and n the number of years, we annex a few of the elementary formulas for £1, from which the result for any sum is obtained by simple multiplication.

(1) *Amount of £1 for a given time at compound interest.*—At the end of the first year the principal (£1) with its interest (i) will become $1 + i$. At the end of the second year the amount will be $(1 + i) + i(1 + i)$, or more simply $(1 + i)^2$, and, generally, *the amount of £1 in n years is $(1 + i)^n$.* Example: To find the amount of £6 in 20 years at 5 per cent. interest. Here i is .05 and n is 20, whence the required amount is 6×1.05^{20} = (by logarithms) 6×2.65 = £15, 18s.

(2) *Present value of £1 due n years hence.*—Since £1 becomes $1 + i$ in one year, by proportion $\frac{1}{1 + i}$, otherwise written $(1 + i)^{-1}$ or v , will become £1 in the same time, and hence the present value of £1 due n years hence is $(1 + i)^{-n}$ (or v^n).

At 5 per cent. simple interest a sum of money doubles itself in 20 years, while at compound interest with the same rate it takes less than 15 years. In 100 years £1 at 5 per cent. simple interest becomes £6; at 5 per cent. compound interest it becomes £131, 10s., or thereby.

(3) **ANNUITIES CERTAIN.**—*Amount of an Annuity of £1 in n years.*—At the end of the n years the last year's annuity will be due, and therefore worth £1; the second-last will be worth one year's interest in addition, or $1 + i$; the third (reckoning backwards), $(1 + i)^2$; and so on to the first year's annuity, which will amount to $(1 + i)^{n-1}$. The amount required is therefore the sum of the geometrical series $1 + (1 + i) + (1 + i)^2 + \dots + (1 + i)^{n-1}$; or, $\frac{(1 + i)^n - 1}{i}$.

(4) *Present Value of an Annuity.*—This is easily found from (3), as the result there found must.

evidently be the present value, improved at compound interest—i.e. multiplied by $(1+i)^n$. Hence the present value is $\frac{1 - (1+i)^{-n}}{i}$; or, $\frac{1 - v^n}{i}$.

Tables for the four classes of values above described, based on various rates of interest, are given in most works on annuities and other handbooks; and various useful results, besides those immediately intended, can readily be deduced from them.—The calculation of *Life Annuities* is complicated by the element of the probability of life, and is treated under ANNUITY.

INTEREST, IN LAW.—The charging of interest was formerly looked upon with great disfavour, and was either forbidden or restricted by the Usury Laws (q.v.), which were not finally repealed till 1839. In English law there is no obligation imposed on the debtor to pay any interest whatever, though the sum has been long due and often demanded. The creditor can always sue for his debt, which is his proper remedy, but he derives no benefit from giving time to his debtor. Therefore, if interest is to be paid, this must be, as a general rule, by virtue of express agreement. A tacit agreement, however, would be presumed and given effect to where it could be proved to be a custom between the parties, or the usage of a particular trade to allow interest. Thus, by the usage of merchants, it has always been usual, when an action has been brought to recover the amount of a bill of exchange or promissory-note, for the jury to add interest from the time it was due. In the case of money due upon an award by an arbitrator interest is due from the day when the award was made. Where money is due on a bond also interest is added from the day it ought to have been paid; and if a surety has to pay money for his principal he can recover it back with interest. In all other cases, if there was no express agreement about interest, none could be claimed. By 3 and 4 Will. IV. chap. 42, sec. 28, a jury may now add interest at the ordinary rate on all debts or sums certain, which are made payable under some written instrument at a certain time; and even if not due under a written instrument, then if a written demand has been made, expressly giving notice that interest will be charged from and after the date of the demand if not paid then, interest will also be due. But even in these last cases it is discretionary in the jury to give the interest, and therefore it is not claimable as a matter of course. As regards compound interest, it is *a fortiori* not claimable in any case, except where it has been expressly stipulated for, or where there is in some particular trade a definite custom to pay interest, and such custom must always be proved. The courts generally name 4 per cent. when interest is decreed for, but sometimes 5 per cent.; and where funds have been misapplied the Court of Chancery charges compound interest at 5 per cent. Pawnbrokers are allowed to charge interest not exceeding a fixed sum. See PAWNBROKING.

In Scotland the law has always been much more liberal in allowing interest to be claimed on outstanding debts, for there the converse principle was acted on, that on nearly all debts whatever interest was claimable either by statute or by common law. Thus, interest is due on bills of exchange, on the amount contained in a homing or charge to pay, on sums paid by cautioners, on the price of lands sold, on money advanced at request, on the price of goods sold if the usual time of credit has expired, and generally on all debts when payment is due and has been demanded. In certain cases principal and interest to a fixed date are accumulated into a capital sum on which interest runs; and the House of Lords, on appeal, may give

decree for compound interest. The courts charge penal interest at the rate of 20 per cent. against factors and trustees who illegally retain trust funds in their own hands. Under the Money-lenders Act (1900) the court may relieve debtors from payment of an excessive rate of interest, notwithstanding any bargain.

Interference, in Physical Science, is a term which refers to a very general class of phenomena depending on the co-existence at one place of two different sets of waves, undulations, or vibrations. Its essential character is well illustrated by the mingling of two sets of ripples produced in any way (such as by the dropping in of stones) on the otherwise smooth surface of a sheet of water. Where crest meets crest, and trough meets trough, there the resultant disturbance is increased; but where crest meets trough, and trough meets crest, the disturbance will be diminished, and even annihilated should the mingling ripples be equal to begin with. In such a case we can observe the interference of individual waves. Now, wherever we have wave-motion, in the wide dynamic sense of the term, there we may have interference-phenomena showing themselves. But if, as in the case of the propagation of sound, light, and electrical waves, the undulations are too small, or of a character too peculiar to be *individually* observed or felt by any of our senses, we cannot hope to have evidence of interference-phenomena unless there is a steady succession of two trains of waves reproducing the same phenomenon at the same place for an indefinite time. Thus, two different rays of light will not in general produce evident interference-phenomena. It is only when they have been brought from the same original source, and made to pursue slightly different paths, that the optical effects of interference are possible. As a simple illustration, take Grimaldi's experiment as modified by Dr Thomas Young (1804), to whom we owe the discovery of the principle of interference and its application to optical phenomena. A ray of light, which for simplicity we shall regard as homogeneous—that is, of one wave-length and colour—is introduced into a darkened chamber through two minute apertures very close together. The two similar divergent rays of light so produced will interfere, and the result, as shown on a screen placed a short distance in front of the apertures, will be a series of bright bands separated by dark spaces. The central bright band, every point of which is equidistant from the apertures, is produced by the superposition of two rays, crest falling with crest, and trough with trough. The next bright band on either side is the locus of all points whose distances from the two apertures differ by a wave-length of light, so that still crest falls with crest, and trough with trough. But at the points that lie in the centre of the intermediate dark space the two rays meet so that crest falls with trough, and trough with crest, and thus produce darkness instead of brightness. The general law is that darkness is produced when the portions of the two interfering rays that coexist at one point were in the original single ray distant from each other by an odd number of half wave-lengths; and that brightness is produced when this distance is an even multiple of a half wave-length. Theoretically an indefinite number of interference bands should be visible; but practically this is not so. The chief reason for the gradual fading of the further bands is the difficulty of obtaining sufficiently pure homogeneous light. If the light is ordinary sunlight it will be found impossible to get really dark spaces, since in this case the component rays, being of different wave-lengths, cannot interfere in the same way. Thus, if the red rays interfere so as to annihilate each other, the blue rays will not do so, but may

on the contrary interfere to intensify each other. Hence arise the coloured bands always to be seen when interference-phenomena are produced with non-homogeneous light. Amongst other optical illustrations of the principle of interference we may mention the coronæ round the sun and moon when they are seen through a fleecy cloud, the spurious bows that fringe the primary rainbow, the colours of soap films and thin plates generally, the colours of mother-of-pearl and diffraction gratings (see SPECTRUM), Newton's rings, and, as a simple experiment, the appearance of a candle or lamp flame when looked at through a fine cambric handkerchief. The phenomenon of spring and neap tides (see TIDES) is another case of interference; so also are shadows, both light-shadows and sound-shadows. Moreover, Hertz of Carlsruhe showed how to obtain and measure the interference of electro-magnetic waves. See MAGNETISM.

Interglacial Beds. See PLEISTOCENE.

Interim, in the history of the Reformation, the name given to certain edicts of the German emperor for the regulation of religious and ecclesiastical matters 'in the meantime' (Lat. *interim*), till they could be decided by a general council. The chief are the *Ratisbon Interim* (at the diet held at Ratisbon in 1541); the *Augsburg Interim* (diet of 1548); and the *Leipzig Interim* (another diet of 1548). See CHARLES V.

Interlaken ('between the lakes'), a village of Switzerland, in the beautiful valley of the Aar, between Lakes Thun and Brienz. Along the Walnut Avenue or Highway between the lakes there is an almost uninterrupted line of hotels and pensions. The village is visited annually by 20,000 to 30,000 tourists, who make it their starting-point for reaching many of the most wonderful sights that the country affords, especially the Bernese Oberland, where are the Staubbach, Lauterbrunnen, the Grindelwald glaciers, &c. The nucleus of the village is a former Augustinian monastery (founded 1130).

Interlineations in a deed are additions or corrections written either on the margin or between the lines. In England interlineations in a deed are not fatal, provided only it is proved that they were made before executing the deed. It is usual to put the parties' initials opposite the place where the interlineations occur, in proof of this, or at least by way of memorandum. In affidavits and other documents the initials should also be put at the places interlined. In Scotland marginal additions ought to be signed, and the fact mentioned in the testing clause, otherwise they may be presumed to have been made after the execution. But interlineations are authenticated only in the testing clause.

Interlocutor, in Scots law, means a finding or judgment of a judge or court in a cause.

Interlude, originally a short piece, usually humorous, introduced between meals or courses, or between the acts of the long Mysteries (q.v.) and moralities, later a separate play, the earliest form of the modern drama, as in the work of John Heywood (q.v.) and Bale. In music an interlude is a short melodious phrase played by the organist (generally extempore) between the verses of a psalm or hymn tune, or as in the German Protestant Church between sections of the verse. It is now in disuse in England. Examples of its artistic use may be found in Mendelssohn's *Elijah* ('Cast thy burthen') and *St Paul* ('Sleepers, wake').

Intermittent Fever. See MALARIA.

Internal-combustion Engines are heat-engines of the class in which the fuel is burned within the working cylinder of the engine itself.

Gas-engines and oil-engines are internal-combustion engines in which the fuel supplied is gas or oil, as the case may be. In all heat-engines there is a working substance which is alternately heated and cooled, and does the work by alternate expansion and contraction of its volume, thereby converting into mechanical form a portion of the energy which is communicated to it as heat. In the steam-engine the working substance is steam, or, to be more precise, a mixture of steam and water of varying proportions. The combustion of the fuel which supplies heat to the working substance goes on outside the vessel or boiler in which the working substance is contained. Hence, the steam-engine is an example of an *external-combustion* heat-engine. But in gas and oil engines, which belong to the *internal-combustion* class, the working substance is made up of the fuel itself—before and after combustion—along with a certain quantity of diluting air. Internal-combustion engines have the enormous advantage that there is no heating surface of metal through which the heat must pass on its way to the working substance. The existence of a heating surface in the external-combustion engine imposes practically a somewhat low limit upon the highest temperature to which the working substance may be raised. In gas or oil engines a far higher temperature is practicable, and the result is that it becomes possible to convert a larger fraction of the heat into work. The theory of Thermodynamics (q.v.) shows that even the most efficient conceivable heat-engine can convert into work no more than a certain fraction of the heat supplied to it—a fraction which is increased by increasing the range through which the temperature of the working substance is caused to vary. This range is much greater in gas or oil engines than in the steam-engine, and the ideal efficiency—that is to say, the fraction of the heat convertible into work—is consequently greater.

The gas-engine was the first internal-combustion engine to reach a commercial stage of development. It will be considered first and somewhat fully, not only for this reason, but also because it affords the best and simplest example for discussing the fundamental principles which underlie the operation of all internal-combustion engines.

From the year 1823 onwards a number of proposals were made by Brown, Wright, Barnett, and others for the construction of engines to work by the explosive combustion of gas. Although in some instances these inventions anticipated later successful engines, and although the details were often carefully elaborated, no practical success was attained till 1860, when an effective gas-engine was brought into public use by M. Lenoir.

Lenoir's engine resembled in appearance a single-cylinder horizontal steam-engine. As the piston advanced it drew in an explosive mixture of gas

Fig. 1.—Indicator-diagram of Lenoir's Engine.

and air. About mid-stroke this was ignited by an electric spark, and for the remainder of the stroke work was done through the pressure of the hot products of the explosion. During the back-stroke these products were expelled to the atmosphere, while on the other side of the piston a fresh explosive mixture was being taken in and exploded at mid-stroke as before. To keep the cylinder cool enough to admit of lubrication it was surrounded

by an external casing within which cold water was caused to circulate. This water-jacket has continued to be a feature of nearly all modern gas-engines. An indicator-diagram from Lenoir's engine is shown in fig. 1. From A to B the gas and air are being sucked in. The rapid rise of pressure from B to C is due to the ignition of the mixture. After C the hot products of combustion go on expanding to the end of the stroke, D, and the pressure diminishes although (as recent investigations have shown) the process of combustion is to some extent continued into this stage. The back-stroke, DA, expels the burned gases at atmospheric pressure.

Lenoir's engine used about 95 cubic feet of gas per horse-power per hour, which is about five or six times the quantity required by the best gas-engines of the present day. Its poor economy was mainly due to the small amount of expansion which the hot gases underwent after the explosion. Another drawback was that the average pressure upon the piston was so low as to make the engine bulky in proportion to the work performed by it. These defects are remedied in modern gas-engines by compressing the mixture before it is exploded, so that a greater range of expansion is required to reduce the burned gases to the atmospheric pressure at which they are expelled. This secures greater efficiency, while at the same time the higher mean effective pressure of the working substance permits an engine of a given size to have more power. Compression of the explosive mixture had been proposed by Barnett as early as 1838, and was a feature in several later patents; but its advantages were first practically realised in the well-known and highly successful engine of Otto, which dates from 1876.

Nine years earlier (in 1867) a gas-engine had been commercially introduced by Otto in conjunction with Langen which, although now obsolete, deserves mention both on account of the success which it achieved and the peculiarity of its action. The Otto and Langen engine was of the free-piston type (originally proposed by Barsanti and Matteucci in 1857). There was no compression of the explosive mixture; it was taken in during the early part of the up-stroke of a piston which rose in a vertical cylinder. Then the mixture was ignited by being brought into momentary contact with a flame through the action of a special slide-valve. Under the impulse of the explosion the piston rose with great velocity to the top of its stroke, being free to rise without doing work on the engine shaft. The burned gases then cooled, and their pressure fell below that of the atmosphere. The piston was therefore urged down by the pressure of the air, and in coming down it was automatically put into gear with the shaft, and so did work, the products of combustion being expelled during the last part of the down-stroke. The engine was excessively noisy, but it took less than half the amount of gas that had been taken by Lenoir's.

Otto's invention of 1876 again halved the consumption of gas, and quickly raised the gas-engine to the position of a commercially important motor. Its success may be judged from the fact that in 1889 there were already some thirty thousand engines of this type in use, of sizes giving from 100 horse-power down to a fraction of 1 horse-power. In the Otto engine the cylinder is generally horizontal and single-acting, with a trunk piston, and it takes two revolutions of the crank-shaft to complete a cycle of operations. During the first forward stroke gas and air are drawn in, in the proportion proper to form an explosive mixture. During the first backward stroke the mixture is compressed into a large clearance space behind the piston. When the next forward stroke is about to begin, the compressed-mixture is ignited, and work

is done by the heated gases during the second forward stroke. The second backward stroke completes the cycle by causing the burned gases to be expelled into an exhaust-pipe leading to the outer air. The clearance space is, however, left full of burned gases, and this portion of the previous charge is allowed to mix with the fresh air and gas which is drawn in during the first forward stroke of the next cycle. Since only one of the four strokes which are required to complete a cycle is effective in doing work, a massive fly-wheel, running fast, is used to furnish a large magazine of energy, and in cases where exceptional uniformity of speed is important—as, for instance, in electric lighting—it is usual to have two heavy fly-wheels. A centrifugal governor controls the engine by cutting off the supply of gas when the speed exceeds a prescribed limit. The cylinder is kept moderately cool by the circulation of cold water in a water-jacket.

In modern engines of all sizes ignition is almost always brought about by electrical means—either a stream of high-tension sparks is caused to flash across a narrow gap between two terminals fixed in a porcelain 'spark plug,' or else a low-tension spark is produced by mechanically breaking a self-inductive circuit at a point situated within the combustion chamber.

Fig. 2 is a copy of an indicator-diagram from an Otto engine. AB is the first stroke of the cycle,

Fig. 2.—Indicator-diagram of Otto's Engine.

and corresponds to the taking in of gas and air at a pressure sensibly the same as that of the atmosphere. BC is the compression stroke. At C ignition takes place and raises the pressure quickly to D. CDEB is the effective forward stroke, and the exhaust-valve is opened for the escape of the waste gases near the end of this stroke at E. The expulsion of the gases goes on from B as the piston moves back to A, and this completes the cycle.

As four strokes are necessary to complete the cycle, an engine working on this principle is commonly spoken of as a 'four-cycle' engine. Practically all modern gas-engines of small size are single-acting four-cycle engines, operating in the way that has just been described.

For a good many years the only fuel available was illuminating coal-gas. This circumstance limited the size of gas-engines to quite small powers—generally less than 20 horse-power—in which the cost for gas, though greater than the cost of coal for a steam-engine of corresponding size, was more than balanced by the greater convenience and saving in attendant's wages. In 1881 Mr J. Emerson Dowson successfully applied his cheap 'producer-gas' to the driving of gas-engines, and in 1895 Mr B. H. Thwaite demonstrated that gas-engines might be driven by the so-called 'waste gases' of the blast-furnace. The gas given off in the distillation of coal for the production of coke is also a suitable fuel. The opening up of these sources of cheap gas has given an immense impetus to the production of gas-engines of large size, and has led to the successful commercial development of engines other than those working on the Otto cycle.

As early as 1881 Mr Dugald Clerk introduced a

'two-cycle' engine, in which an explosion occurred once in every forward stroke instead of once in every alternate stroke, as in the Otto or 'four-cycle' engine. This was accomplished by employing an auxiliary piston in a separate cylinder to draw in a charge of gas and air and deliver it into the main cylinder just after the main piston had completed its working stroke. The engine did not achieve much success at the time, as the four-cycle engine proved to be better suited for small powers; but for the large units using cheap gas of low calorific value which are now common, the Clerk or two-cycle engine gives excellent results.

Fig. 3 shows the Oechelhäuser engine, which is an adaption of the Clerk cycle. A long cylinder open at both ends has two pistons; the front piston is driven from the middle crank-pin in the usual way, and uncovers a ring of exhaust-ports towards the end of its outward stroke. The other piston is connected to a back cross-head, which is coupled up by side-rods to the two outer crank-pins, which are both at 180 degrees

Fig. 3.—Oechelhäuser Engine.

from the centre crank. This back piston uncovers two rings of admission-ports just before the end of its outward stroke, the first for air and the second for gas. An extension of the main piston-rod behind the back cross-head carries the piston of a double-acting pump, one side of which supplies the air and the other gas to separate receivers surrounding the cylinder. In the position in which the engine is drawn in the figure the exhaust gases are being expelled while fresh gas and air are entering at the other end of the cylinder. An instant later all the ports are covered, and the mixture is being compressed between the two pistons as they move towards each other. The charge is then fired, and the two pistons are driven apart, so producing one effective stroke per revolution. It should be noted that as the pistons travel outwards it is first the exhaust-ports which are overrun; this relieves the pressure in the cylinder. Then the air-ports are uncovered, which allows a quantity of air effectively to expel or 'scavenge' the products of combustion of the previous stroke before fresh gas is admitted. An attractive feature of the design is that valves and piston-rod glands are dispensed with, and also that the force of the explosion is balanced between the two pistons and does not produce any reaction between the cylinder and bed-plate. This circumstance makes it easy to give the cylinder-liner freedom to expand and contract under the alternate heating and cooling to which it is subjected.

Another engine which employs two opposed pistons in each cylinder, and may therefore be regarded as a modification of the Oechelhäuser type, is the Fullagar engine. The long return connecting-rods, and the necessity for the use of a three-throw crank-shaft, have been done away with by arranging two cylinders side by side, and coupling the lower piston of one to the upper piston of the other, and *vice versa*, by means of light diagonal steel tie-rods. If the stroke is fairly long in relation to the bore, the angularity of these ties is not excessive, and is, in fact, considerably less

than the maximum angularity of the connecting-rods. The thrust due to the diagonal ties is taken by outside cross-heads, which can be kept cool and well lubricated, so that the friction-loss due to this cause is very small. The whole design is attractive in that it is at once simpler, cheaper, and more compact than the Oechelhäuser engine. Only the lower pistons are connected to the crank-shaft by single connecting-rods, so that a plain two-throw crank, with cranks at 180 degrees, suffices for both cylinders and all four pistons. The Fullagar type of engine-frame is now being adopted extensively for Diesel engines, both stationary and marine, in sizes up to several thousand horse-power.

The Körting engine (see fig. 4), which was brought out shortly after the Oechelhäuser, is another example of the two-cycle type which is double instead of single acting. It consists of a

Fig. 4.—Körting Engine.

long cylinder with a ring of exhaust-ports in the centre. The piston is also made so long that the exhaust-ports are only uncovered when it is nearly at the ends of its stroke. Air and gas injected by separate pumps are admitted at the right moment through mechanically controlled valves situated at each end of the cylinder.

The four-cycle engine has also been adapted to generate large powers. Two double-acting cylinders are generally arranged in tandem. It is then possible to time the explosions so as to secure an impulse every stroke. In such engines a compression also occurs at the end of every stroke; this leads to a cushioning action, which is helpful in overcoming the inertia effects due to the moving parts. Engines of the double-acting four-cycle horizontal kind just described are often spoken of as the Nürnberg type. They were first brought out in Germany in 1902, and have been built both in Europe and America, in sizes ranging from 1000 to 4000 horse-power.

The governing of small engines is usually accomplished on the 'hit or miss' system—i.e. the gas-valve is either lifted to its full height, or, if the speed is in excess of an assigned value, the governor displaces the lifting mechanism, so that the gas-valve does not open at all. With the object of obtaining greater regularity in running the device is sometimes arranged so that the extent to which the gas-valve opens is determined by the governor. By this so-called 'quality governing', a rise of speed is checked by reducing the amount of gas instead of altogether cutting off the supply. The system is not very successful in practice, as when the mixture is weak there is a tendency to miss fire, and even if this does not occur, the efficiency of the explosion is considerably impaired. For large engines it is usual to employ 'quantity governing'—i.e. the proportion of gas to air is kept constant, but the volume of the mixture drawn in to form

the charge depends upon the position of the governor.

As it is easy to determine the total heat liberated by the explosion of a charge of gas and air in known proportions, and also the amount of heat necessary to raise the temperature of the products of combustion at constant volume, say from 60 to 61 degrees Fahrenheit, it would seem a mere matter of proportion to calculate the total rise in temperature when the mixture is fired in a closed vessel. It is found, however, that the maximum pressure corresponding to the maximum temperature calculated in this way is really about double of what actually occurs. The old explanation of this discrepancy was that the process of combustion was still far from complete at the moment of maximum pressure. It was thought that up to the highest point of an indicator-diagram, such as that shown in fig. 3, only about 60 per cent. of the whole heat of combustion was generated, and that the remaining 40 per cent. was liberated slowly during the subsequent expansion. This action, called 'after-burning,' was supposed to go on after the mixture had been ignited throughout its whole volume. But it is now generally accepted that 'after-burning' in this sense does not take place to any appreciable extent, and that the principal reason why the maximum pressure calculated as indicated above is not actually realised is because the specific heat of the products of combustion at constant volume increases considerably at the high temperatures attained during the explosion. It is true, however, that an appreciable time is taken for the flame kindled at the sparking-plug to travel to all parts of the mixture. The time taken is longest in the case of weak mixtures at low pressures, the combustion spreading more rapidly in richer mixtures or in mixtures which are highly compressed.

Although the maximum temperature attained by the gases within the cylinder of the engine is less than might have been expected, it is nevertheless some 3000° F. or more, which is higher than the melting-point of cast-iron, while the temperature of the walls has to be kept low enough not to burn the oil-film needed to lubricate the piston. The necessity of employing a water-jacket is thus evident, and in large engines it is found necessary to arrange a water-circulation to cool the piston: sometimes the exhaust-valves (if any) are also water-cooled. Since the volume of a cylinder increases as the cube of its linear dimensions, whereas its surface increases only as the square, it is clear that the difficulty of keeping the cylinder-walls reasonably cool increases with the size. At present the practical limit of size seems to be reached in a cylinder 48 inches in diameter. If we adopt a mean effective pressure of 65 lb. per square inch, and a piston-speed of 1000 feet per minute, the power developed within a cylinder of this diameter in the case of a double-acting two-cylinder engine is about 3600 horse-power, which would seem to be about the maximum output obtainable from a single cylinder.

As regards consumption, useful figures to remember are that a gas-engine working on town illuminating gas will require 15 to 22 cubic feet per brake-horse-power-hour according to size, the larger engines being the more economical. A small engine supplied from a suction gas-plant will require about 1 lb. of anthracite or 1½ lb. of coke per brake-horse-power-hour. In the case of a pressure gas producer plant supplying large engines the fuel consumption may be as low as 0.75 lb. of bituminous slack per brake-horse-power-hour.

In early Otto engines only about 14 per cent. of

the total energy supplied in the fuel was available on the brake; in modern engines the ratio may be over 30 per cent. This great improvement of efficiency has been principally brought about by employing increased ratios of compression. By making certain assumptions, it may be shown that the efficiency of an ideal internal combustion engine is $(1 - (\frac{1}{r})^{\gamma-1})$, where r is the ratio of compression, and γ is the ratio of the specific heat at constant pressure to the specific heat at constant volume of the working substance. Since the specific heats of the gaseous mixture in the cylinder, both before and after combustion, are practically the same as in the case of air, for which $\gamma = 1.4$, the expression becomes $(1 - (\frac{1}{r})^{0.4})$. Although the assumptions

made in the proof of this formula do not by any means apply under actual conditions, it furnishes a somewhat useful standard with which the action of real engines may be compared. This is the so-called 'air standard' adopted by a Committee of the Institution of Civil Engineers. In tests made by Professor Hopkinson on a 40-horse-power Crossley engine in 1908, the brake thermal efficiency was 0.32, and the indicated thermal efficiency was nearly 0.37. The ratio of compression was 6.37, for which the corresponding 'air standard' efficiency is 0.52, so that 61.5 per cent. of the 'air standard' efficiency was actually realised. Professor Callendar has estimated that, taking into account the increase in specific heat of the working substance at high temperatures which actually occurs, an ideal engine could only realise about 75 per cent. of the 'air standard' efficiency, so that the maximum obtainable efficiency is really only $0.75 \times 0.52 = 0.39$. This means that the real margin for improvement is only the difference between 0.32 and 0.39.

In some tests made by the Institution of Civil Engineers sufficient measurements were taken to allocate the principal sources of loss. If the total energy supplied in the fuel be denoted by 100, then, in round numbers, 40 was carried away in the hot exhaust gases, and 25 in the jacket water and by radiation, leaving 35 as converted into indicated work. The mechanical efficiency of a gas-engine when fully loaded—i.e. the ratio of the brake-horse-power to the indicated horse-power—is generally about 0.85.

The petrol-engine, which is now so extensively used for automobiles, aeroplanes, &c., dates from 1883, when Daimler produced his first small engine. It works in the same way as the Otto cycle gas-engine, the only difference being that a 'carburettor' has to be added, by means of which the air on its way to the cylinder is intermingled with a suitable proportion of oil vapour. The petrol, benzol, or other motor spirit used in these engines is so volatile, even at ordinary atmospheric temperatures, that it is only necessary to allow the air that is being drawn into the cylinder to suck up a spray of petrol through a small orifice. It is important, however, that the quantity of petrol taken up should always be such as will result in a suitable explosive mixture. In a motor-car, for instance, where the engine is being continually called on to work at different speeds and torques, this is no simple matter. A remarkable amount of ingenuity has been displayed in the invention of carburettors, which automatically tend to maintain a suitable 'richness' of the mixture at all speeds and loads.

The general features of the automobile-engine are now fairly standardised. The cylinders, of which there are generally four or six, are arranged 'in line' with the crank-shaft beneath. In aero-engines, which are required to develop several

hundred horse-power at a speed of about 1500 r.p.m., more and larger cylinders are required. In the 'radial' type the cylinders are disposed radially round the crank-shaft. In the 'rotary' type the cylinders are again radially disposed, but, instead of being stationary, the cylinders, which are air-cooled, rotate like a fly-wheel around a fixed crank-pin, carrying the propeller with them. In the 'Vee' type there are two lines of stationary, water-cooled cylinders. Seen in end elevation, the axes of the two lines of cylinders include an angle of about 60° , and converge on the centre of the crank-shaft, which is situated at the apex of the V. Opposite cylinders drive the same crank-pin. The arrangement evidently enables twice as many cylinders to drive a given crank-shaft as the simpler 'in-line' type.

The Diesel oil-engine, which dates from about 1895, possesses some interesting characteristics which distinguish it from all other internal combustion engines employing the Clerk or Otto cycle. It was invented by Herr Rudolph Diesel, who set out to produce an engine which would work on a cycle approximating as closely as possible to the ideal necessary for obtaining maximum theoretical efficiency. A typical indicator-diagram is shown in fig. 5. During compression air only is present, and the ratio of compression is so high that the pressure is raised to some 500 lb. per square inch. Oil is now injected into the cylinder in a fine state of subdivision by means of an external air supply

Fig. 5.—Indicator-diagram of Diesel Engine.

at a pressure of about 650 lb. per square inch. The oil burns as quickly as it enters the cylinder without the need of any ignition device, for the temperature of the air within the cylinder is already some 1000°F. , in virtue of the high compression which it has just undergone. The combustion of the oil as it is injected during the early portion of the working stroke takes place gradually, so that the pressure never exceeds that attained at the end of compression; but remains practically constant until the supply of oil is cut off, after which expansion proceeds in the usual way, followed by two idle strokes in which the burnt products are expelled, and then a fresh charge of air drawn in ready for the compression stroke which follows.

That the Diesel engine is, in fact, highly economical is proved by the fact that even for small sizes the makers are prepared to guarantee a consumption of oil which will not exceed 0.5 lb. per hour for every horse-power obtainable on the brake. This is about half the amount of oil that would be required by an ordinary oil-engine working on the Otto cycle. Reliable tests have shown that the thermal efficiency of the Diesel engine, reckoned as the ratio of the indicated power to the energy supplied in the fuel, may actually exceed 0.4, which is about twice as high as can be obtained in any form of steam-engine, and appreciably higher than in ordinary internal-combustion engines. On the other hand, the mechanical efficiency of a Diesel engine is somewhat low, due largely to the work that has to be expended on the air compressor used for injecting the oil, with the result that, measured by

the return on the brake, the thermal efficiency of the Diesel engine is not much higher than can sometimes be obtained by a gas-engine working on the Otto cycle.

A strong competitor of the Diesel engine in the smaller sizes is the Semi-Diesel or Hot Bulb or Surface Ignition engine, which differs radically from the 4-stroke Diesel in many respects. In the majority of cases it is a 2-stroke engine using simple ports for inlet and exhaust, which are opened and closed by the action of the piston. In the smaller sizes of this type the only valve in the cylinder-head is the fuel-valve, and even this is not mechanically operated, but is opened by a sudden rise in pressure in the fuel system, due to the action of the cam-operated fuel-pump. The fuel-spray is directed on to the hot bulb or other uncooled surface, and is thereby vaporised and ignited. For starting-up, this surface has to be heated either electrically or by means of a blow-lamp. Crank-case compression is used, air being drawn in through the light flap-valves of flexible metal in the crank-case on the up-stroke of the piston. The compression pressure of these engines is low, about 150 lb. per square inch, and their indicated mean effective pressure is low also, about 48 as compared with 90–100 lb. in the Diesel engine, but, it being a 2-stroke engine, the rating for a given cylinder-diameter is about the same as that of a 4-stroke Diesel. The fuel consumption of Semi-Diesels is higher than that of other types, about 5 lb. as against 4 lb. per b.h.p. hour at full load, and they are not very flexible, owing to the tendency of the hot bulb to grow cold at light loads or too hot at heavy loads, though in certain engines this tendency can be corrected by directing the spray on to a different part of the bulb. On the other hand, these engines are remarkably simple, and can hold their own by reason of this and of their low first cost.

A recent innovation in the field of stationary internal-combustion engines is the high-compression mechanical or solid-injection engine, or cold-starting engine as it is often called, to distinguish it from the semi-Diesel. These engines have a slightly lower compression-pressure than the full-Diesel, and a slightly higher maximum pressure. The fuel consumption is about the same. As in the Diesel, ignition is by the heat generated by compression. Owing to mechanical injection being used, the air-compressor and mechanically operated fuel-valve are eliminated. The fuel-pump is operated by a sharp-nosed cam, which gives a sudden rise in pressure in the fuel system. This sudden rise opens the needle-valve of the atomiser in the cylinder head, and fuel enters through grooves and small holes or slits in a finely atomised form.

The Still engine, which began to attract serious attention in 1920, represents a highly ingenious attempt to confer upon a high-efficiency internal-combustion engine the elasticity and superior operating characteristics of the steam-engine. It consists of an internal-combustion engine, the cylinder-jacket of which is in communication with the water space of a steam-boiler. The water, on its journey from the boiler to the jacket, is taken *via* a tubular heater, through which the hot exhaust gases are discharged. The steam and water leaving the jacket are led back to the steam space of the same boiler. The exhaust gases, after passing through the tubular heater, impinge upon coils, through which the cold feed-water is pumped, and in this way give up still more heat before being allowed to escape. Steam taken from the top of the boiler passes through a stop-valve, and is admitted through an ordinary slide-valve into the steam cylinder, which forms the underside of the

combustion cylinder. Thus the top end of the cylinder functions as an internal-combustion engine, and the bottom end works as a steam-engine. The piston is driven down by the force of explosion and pushed up by steam admitted beneath it. The efficiency of the engine is remarkably high. This is to be expected, in so far as much heat usually carried away by the hot exhaust gases is made to generate steam, which in turn does additional work on the underside of the piston. Besides this, the alternation of steam and explosive mixture in the same cylinder proves to be a happy combination, in which each reacts on the other to the mutual advantage of both. The boiling water in the jacket keeps the cylinder walls at a uniform and unusually high temperature. Again, due to the preheating effect of the combustion stroke, no condensation occurs when steam is admitted. Incidental advantages are, that taking heat from the piston during the expansion stroke is an excellent means of keeping it cool, while the cushioning effect of the steam under the piston helps to reverse the reciprocating masses at the bottom dead centre, thereby reducing frictional losses. By this system a fuel consumption of 0.356 lb. of fuel-oil per b.h.p. hour has been obtained, which corresponds to a brake thermal efficiency of 0.392 at full load. This is probably the highest efficiency that has as yet been obtained from any heat-engine. Scott's Shipbuilding and Engineering Co. have developed the Still engine for marine work. Besides high economy in fuel, the Scott-Still marine-engine has the advantage that the use of compressed air is entirely eliminated, since the fuel-oil is injected by pressure only (solid injection), and steam is used in place of air for starting and manœuvring purposes.

International Justice, PERMANENT COURT OF, was opened at The Hague in 1922. See LEAGUE OF NATIONS.

International Labour Office. See LEAGUE OF NATIONS.

International Law. Under this designation are included two distinct branches of jurisprudence, known respectively as Public International Law and Private International Law. Public international law regulates the relations of states to states; private international law is concerned exclusively with the legal relations of private individuals, determining by the law of what nation such relations shall be governed in each particular case. Further, it has to be noted that a variety of relations may occur wherein a state and the citizen of another state are the subjects. Here the law is public on one side and private on the other, as is the law administered in prize-courts. In practice, however, such cases are treated under public international law.

Public International Law is the aggregate of the rules which govern sovereign states in their relations and conduct towards each other.

In ancient Greece certain rules were observed by the autonomous and independent city-states in their dealings with one another. These rules constituted a body of Hellenic public law recognised as applicable to transactions between states within the Hellenic circle. So the Romans in their formal intercourse with neighbouring communities observed, from a very early period, a body of rules, known as the *jus fetiale*. This rudimentary fetial law underwent important developments during the era of the republic, and its rules were extended and applied to a considerable variety of formal dealings between Rome and other states. But during the whole period of the empire, while the municipal law of Rome was achieving its high destiny, the jurists were, by their theory of a universal empire, shut out from formulating any general system of rules applicable to the relations of independent states. Nevertheless the Roman jurists, by their enunciation of the doctrine of the *jus naturale*—the doctrine that there exists a natural order of right, *naturalis ratio*, which is the true foundation of law, and which it is the aim of jurisprudence to discover and embody in the rules of positive law—laid the foundation upon which, many centuries after the fall of the Roman empire, modern international law was built. Meanwhile, after the Roman empire had given place to separate kingdoms, the peoples of Europe, closely bound in the fetters of feudalism, were painfully struggling through a period of transition, out of which were to emerge the great European monarchies. The Roman tradition and conception of a single and undivided empire still lingered among lawyers and statesmen, and probably contributed to postpone any effort to evolve a *jus inter gentes*. During this long period, however, the need of some definite system of international law was in some measure practically supplied by two powerful influences—the authority of the church and the institution of chivalry. The magnificent organisation of the church, besides checking violence and controlling in some degree the turbulence of princes, enabled the pope, taking advantage of the lingering notion of universal sovereignty, to act as arbitrator in a great variety of controversies ranging in importance from the disputes of private individuals to the adjustment of difficulties of serious international concern. The institution of chivalry also, by introducing declarations of war by heralds and a more humane treatment of the vanquished, and generally by inculcating the virtues of fidelity and magnanimity, tended to assuage the horrors of war. Meantime the revival of commerce and the growth of the new commercial cities gave rise to several primitive maritime codes, whose publication did much to regulate the relations of states in mercantile matters. The most famous of these codes were the Laws of Oléron, which ruled the sea-traffic of the Atlantic coasts of western Europe, the Laws of Wisby, which obtained in the North Sea and the Baltic, and the Consolato del Mare, which regulated the commerce of the Mediterranean.

With the 16th century came a new era and a rekindling of intellectual life. The medieval order in the political sphere fell into decay. The Reformation shattered the influence so long beneficially exercised by the Roman curia as a court of international appeal. The great political and religious struggles of the period gave rise to wars which were waged with unrestrained ferocity. Men felt that an effort must be made to find some basis of international order if Europe was to be saved from what threatened to become international anarchy. The renaissance had given a fresh impulse to the study of Roman law, and it was in the *jus*

naturale, as enunciated by the Roman jurists, and in the application of that old doctrine to states in their mutual relations, that all the early writers on international law sought to find a remedy for the lawlessness obtaining in international affairs. Towards the close of the 16th century notable efforts were made by lawyers and scholars in various European countries to apply the conception of the *jus naturale* to the regulation of the mutual dealings of states. The principle that the conduct of states is subject to law was clearly promulgated by Ayala, whose *De Jure et Officiis Bellicis* was published at Douai in 1582. Other early works of enduring reputation were the *De Jure Belli* of Alberic Gentilis, published in 1598, and the *De Legibus et Deo Legislatore* of Francisco Suarez, published in 1612. Of the workers who were thus engaged in the discovery of a principle which would be generally accepted as a foundation for a new international order, immeasurably the greatest was Hugo Grotius, who was born in 1583, the year after Ayala's work was published. Grotius, who combined profound learning and keen philosophic insight with a large experience in public affairs, is justly regarded as the founder of international law. His famous work, *De Jure Belli et Pacis*, was published in Paris in 1625. Grotius, starting with the conception of a rule of natural reason binding on states *inter se*, worked out the applications of that principle to the relations of states, regarded as units and recognised as analogous to 'persons' in law. He investigated the universal moral and social conditions of governments and laws, and expounded what such governments and laws are, or ought to be, as determined by conformity to these conditions. He reduced a huge mass of materials into an intelligible system, and presented it in a form that appealed to statesmen and men of action as well as to scholars and thinkers. The legal conceptions and principles which he used and applied were fundamentally Roman in origin. As such they commanded the approval and acceptance of lawyers and statesmen; for, from the 16th century, Roman law was generally received throughout Western Christendom, with the partial exception of England, as a kind of universal law. The success of the work was rapid and decisive. In the treaty of Westphalia, which in 1648 ended the Thirty Years' War, the principles laid down by Grotius were recognised as furnishing a stable foundation on which to construct the jural relations of states and the new public order of Europe.

Since the time of Grotius, there has been much controversy as to the essential nature and source of international law. In continental countries the view generally adopted is that, as laid down by Grotius, international law is the application of principles and standards of right, attested by reason and experience, to international relations, and that these principles and standards furnish the rules which determine, or ought to determine, the relations of states to one another. Thus Bluntschli (*Das Völkerrecht*, sect. 1) defines the law of nations as 'That recognised universal law of nature which binds different states together in a humane jural society, and which also secures to the members of different states a common protection of law for these general human and international rights.' In England, on the other hand, the majority of writers on international law take the view that it has its source in international consent, and consists of the aggregate of the rules expressly or implicitly agreed on by states as regulating their conduct and relations to one another. This doctrine, which won its way into English jurisprudence chiefly through the teaching of Bentham, whose principles were worked out and more specifically applied by

Austin, has been accepted by the courts in England. Thus in *The Queen v. Keyn*, 1876, 2 Ex. D. 63, Lord Usher, at p. 131, observed: 'The authorities seem to me to make it clear that the consent of nations is requisite to make any proposition a part of the law of nations. This assent is to be assumed to the logical application to given facts of the ethical axioms of right and wrong.' Whichever of these views be adopted, it is recognised—increasingly recognised—that the great object of the law of nations is to secure or realise justice through legal means; and that ethical principles of right and justice, so far as applicable to the relations of states, furnish a test not only for existing rules, but also for the adoption of new rules demanded by the exigencies of international life. In short, ethical justice is to international law exactly what, according to the doctrine of the Roman jurists, it is to any system of national law.' But it cannot be cited to overrule the positive precepts either of national or international law. For, just as the legal obligations of an individual citizen are determined not by a moral ideal but by the laws in force within the state, so the measure of the legal obligations of a state is to be found not in an appeal to a moral ideal but in the rules which are received as positive law by the body of states. The positive rules of international law embody the practical morality which nations in general recognise as binding upon them, and furnish the only competent evidence of what that standard is.

There is a further question whether international law can properly be said to possess the essential characteristics of law. If the term law, as Austin and the English analytical school maintain, is to be confined to rules enforced by a determinate authority, the rules of international law are clearly excluded from the category of legal rules, and fall to be regarded merely as moral rules sanctioned by public opinion. But it is now conceded that, having regard to the history and development of law, the scope of the term law cannot be limited to rules of which the breach is redressed or punished by a force irresistible to the individual and regularly applied by courts. Historically law—the law of a state—does not owe its origin to the political power of the state; nor is it invariably enforced by a determinate authority. It has its origin in the customary rules observed by the community before the state comes into existence; that is to say, before the community is politically organised. Further, even after a community begins to use its powers in some organised way to compel obedience to certain rules, the means and processes whereby the community exercises its coercive powers are imperfect and precarious in operation. There is, indeed, a long period during which the customary rules are enforced only, or mainly, by processes of self-help recognised by the community as rightly exercisable by individuals who have suffered injury by a breach of the customs. The customs or observances of such a community, although the breach of them is redressed or punished only by a legalised self-help, are recognised as being within the scope of the term law. The analogy, indeed, between such customary rules in an imperfectly organised community, and the rules of international law is, in many ways, very close and instructive. The rules observed by states in their dealings with one another are habitually treated as law and are regarded as having the force of law. The conceptions embodied in the modern law of nations are legal conceptions, derived mainly from Roman law. It has been built up by the application of legal principles and by legal reasoning. It is true that the breach of international law has

not hitherto been punished or redressed by any force regular in its action and irresistible to individual states. But the League of Nations represents machinery for ascertaining and formulating the collective will of an organised community of states, and the International Court of Justice established under it holds out the promise that the rules of international law may be more authoritatively interpreted and more regularly applied. As things are, international law may properly be described in the words of President Wilson as 'law without a forceful sanction.'

It remains to consider the sources of international law, in the sense of the agencies by which its rules are ascertained. The part taken by jurists in building up this branch of jurisprudence has been conspicuous. Their task has been to tabulate precedents, to deduce and test principles, and to bind together the vast mass of materials, moral, legal, and historical, into a coherent system. The works of a long line of eminent writers have contributed powerfully not only towards a clearer understanding of the principles and rules which govern the intercourse of states, but also towards the creation and education of opinion by which the range of this branch of law has been enlarged. Another important factor in the formation of international law is to be found in treaties. Considered as sources or evidences of the law, the most important treaties are those which purport to be declaratory of existing law or formative of new law. Apart from such 'law-making' treaties, a series of treaties between different states containing similar stipulations for the settlement of matters in dispute between the signatories may have important effects on consuetudinary law, and in this way may indirectly affect other states which have not been parties to them. Again, many rules may be traced to the judgments of tribunals of international arbitration and other mixed courts. The decisions of prize-courts—which are courts set up by belligerents to try disputes between their own governments and subjects, and the governments and subjects of other states—are often valuable as precedents, and as furnishing evidence of international usage. The general authority of such decisions is dependent on the reputation enjoyed by the judges. But the principles laid down in the judgments of such judges as Lord Stowell in England, Portalis in France, and Story in America, have been accepted by other courts in other countries as trustworthy, and have had a profound influence in moulding international practice. The American Judge Kent (q.v.), referring in particular to the judgments of Lord Stowell, has borne this testimony: 'There is scarcely a decision in the English prize-courts on any general question of public right that has not received the express approbation and sanction of our national courts.' Among other sources of modern international law may be mentioned declarations of responsible statesmen, opinions of the law officers of governments, state papers on matters in dispute between governments, and instructions issued by states to their armed forces or to their diplomatic agents.

The communities whose relations are governed by international law are independent states. While 'independence' is predicated by international law of all the states who are its subjects, nevertheless international jurisprudence rests on the principle that these several states, as members of the community of nations, are really mutually interdependent. The reality of such interdependence is every day becoming clearer with the increase of complexity in the social, commercial, and political ties by which the nations are bound to one another.

States are recognised as analogous to persons in law—juristic persons having legal rights and legal obligations. The marks of a state, as the term is used in international law, are that the community constituting it is organised for a political end, that it possesses definite territory, that it is represented by a government which exercises exclusive control over all persons and things within its territory, and that its external relations are regulated by it independently of the will of any other community. To these characteristics is added the requirement that it must exhibit reasonable ground to believe that its existence has the element of durability. Theoretically a community possessing these attributes of state-existence is a state; but, nevertheless, its accession to the family of nations dates from its recognition by other powers. Recognition may take place by formal declaration, which may be embodied in a treaty that deals also with other matters, or it may be effected informally by accrediting ministers to the state. Conditions may be attached by the recognising states to their recognition. Recognition by one state in no way binds other states. Each state indeed must be allowed to judge for itself whether a community claiming to be recognised does actually possess the essential characteristics of a state. The quickness or slowness of recognition is often determined by political sympathies; but when a community *de facto* possesses the essential attributes of a state, other powers cannot continue for an indefinite time to refuse to acknowledge its rights to be treated as a state. The legal doctrine that states are analogous to persons in law carries with it the doctrine of their equality before the law. The doctrine of equality holds in proceedings before a court, whether it be a court of arbitration or the International Court of Justice. But the fiction of an equality of legal rights is hard to reconcile with the facts of international life, and it has no application where redress is sought by means of 'self-help.' Further, the trend of recent history seems to be not in the direction of the theory that independent states, however different in size and power, are all equal in the view of the law of nations, but rather in the direction of acknowledging a primacy on the part of the foremost powers of the civilised world. The advances towards self-realisation of the international community, and the undertaking by that community of legislative and administrative functions, make it increasingly difficult to maintain the old theory that states are equal in matters of political right.

A state is not sovereign in the sense of international law if there are any limitations upon its power to enter into relations with other states. Such a state, however, may be a member of a confederation and exercise certain powers giving it a qualified international status. Another form in which part-sovereignty occurs is that of protectorates. In some cases the protected state is left free from interference within its own territory. In other cases the protecting state exercises a certain authority within the territory of the protected state. Generally speaking, a protectorate possesses all competence in international affairs which it has not specifically resigned. Another class of states having only a qualified status are states under the suzerainty of others. Such a state possesses only such competence as has been specifically conferred upon it by the suzerain. The restrictions imposed by the Peace Treaties of 1919 on certain new states which then came into existence, and the provisions of the Covenant of the League of Nations with regard to mandated territories, have added to the numbers

of states in possession of a qualified or partial sovereignty.

Difficult questions arise when a portion of an existing state rises in rebellion, and sets up a separate government over a considerable portion of the national territory, or when organised bodies of men are, for political purposes, in armed hostility to an established government. A community attempting by armed hostility to free itself from the jurisdiction of the parent state may, under certain conditions, be recognised as a belligerent. The conditions warranting such recognition are that the end which the community in revolt seeks is political; that the hostilities are of the character of war, and are carried on in accord with the laws of war; that the government of the revolting community is in the hands of a responsible organisation; and that the revolt has attained such proportions as to affect the rights and interests of other states. The effect of recognising a revolting community as having the status of belligerents is that the community is, so far as the prosecution of hostilities is concerned, accorded by the recognising state all the privileges of a state.

A state has proprietary or quasi-proprietary rights over the territory occupied by the state-community, and subjected to its sovereignty. The definite boundaries of the state territory are ascertained by occupation, prescription, or treaty. The right of a state over its territory exists for the purposes of government, and comprises the right to act within the limits of the territory upon or against all persons found there, and to dispose of all real and personal property within the territory, as, in the judgment of the state, the purposes of government may require. Lakes and land-locked waters not directly communicating with the ocean and wholly surrounded by the land territory of a single state, form part of the dominions of that state. The state also has an exclusive jurisdiction over that portion of the sea which is closely adjacent to its own territory. The generally recognised rule is that this littoral jurisdiction extends to a distance of three miles from low-water mark. This distance was defined by the supposed range of a gun in position. Within the three-mile limit the jurisdiction extends to commercial regulations, rules for pilotage and anchorage, sanitary and quarantine regulations, revenue and general police. A somewhat wider limit is, however, sometimes claimed and conceded for special purposes. Thus under a convention signed at Washington in 1924 between Great Britain and the United States, the American authorities may board British vessels suspected of committing, or attempting to commit, offences against the Prohibition laws of the United States, provided that the right is not exercised at a greater distance from the coast of the United States or of its territories than can be traversed in one hour by the suspected vessel. Both the parties, however, expressly declare that these provisions are not to be regarded as implying an intention to depart from the three-mile rule recognised as generally applicable to the territorial rights of a state over waters. The civil and criminal jurisdiction of a state extends to all its ships on the high seas or within its territorial waters, and to its public vessels everywhere. In the class of public vessels are included ships of war, and vessels engaged in the service of the state and in command of government officers. Over private vessels in foreign waters the amount of jurisdiction claimed by different states varies. The general principle, as shown by practice and by treaty stipulations, is that disorders which disturb only the peace of the ship or those on board are to be dealt with exclusively by the sovereignty of the home of the

ship, but that those which disturb the public peace may be suppressed, and, if need be, the offenders punished, by the proper authorities of the local jurisdiction. If, however, the local jurisdiction is not asserted, the state to which the vessel belongs may properly exercise its concurrent jurisdiction. To the rule that the jurisdiction of a state extends to all persons and things within its territory, exceptions are recognised in the case of foreign sovereigns and their suites when visiting a foreign country in their official capacity, and in the case of diplomatic agents or other officers commissioned to transact the political affairs of the state abroad. This immunity from local jurisdiction has been called *exterritoriality*. The persons to whom such immunity is granted are regarded as being, for purposes of jurisdiction, within the territory of their home state, and beyond that of the state in which they are geographically.

The rules of international law regulating the intercourse of nations in times of peace receive in practice regular observance. On the other hand, the experience of the Great War has shown how feeble is the sanction for the observance of rules—even rules passed with great solemnity at the Hague Conferences—for regulating the conduct of war. It has become evident that the attempt to disarm war of its horrors is an idle dream and a dangerous delusion, and that the aim of international law must lie in the more practical task of removing the causes of war and devising means by which the several peoples may work out their destiny and their future, secure and unafraid. The Covenant of the League of Nations sets forth that the purpose of the League is to promote international co-operation and to achieve international peace and security. The establishment of the League and of the great international organs dependent on it has already brought about results of far-reaching importance in international law (*vide* LEAGUE OF NATIONS); but the peaceful solution of the international problems which must inevitably arise depends even more on the education of public opinion in the several countries and on the development of a spirit of understanding, tolerance, and conciliation.

The more important departments of public international law are dealt with in separate articles.

Private International Law is that department of law which arises from the fact that there are in the world different territorial jurisdictions administering different systems of laws. The subjects of this branch of jurisprudence are private individuals, and its rules are administered by national courts. The majority of the relations in which human beings stand to each other are in their nature universal, and entirely independent of the states to which the parties belong. Thus an individual may possess real property in a state other than that of his domicile, or he may enter into a contract or execute a testament in a country different from either. As, in general, each of these countries is governed by a distinct system of laws, it is frequently a question under which system the particular relations fall. In the event of an action becoming necessary, is he to appeal to the municipal laws of his native country or domicile, or to that of the place in which the property is situated, or to that in which the contract was entered into, or in which the testament was executed? The whole of the doctrines of private international law accordingly resolve themselves into the single doctrine of the localisation of such legal relations. This branch of law determines no legal relations whatever; it simply determines in what national jurisdiction an action ought to be brought, and by what national law it ought to be decided. The

collection of rules for thus determining which system of law is to be applied in cases which contain a foreign element is also commonly known as the 'conflict of laws.'

According to the famous rules of Foelix and Huber, which were long accepted as the fundamental propositions on which private international law was founded, all the effects which foreign laws can produce within the territory of any nation depend absolutely on the consent of that nation, either express or tacit. The sole foundation for the whole system was found in the voluntary and reciprocal good-will of nations (*comitas gentium*). But, in fact, enforcement in the courts of one state of rights duly acquired under the laws of another state is necessary to justice, and the whole principle of this branch of law is a direct corollary from the doctrine of recognition. The right and duty of mutual confidence involved in the doctrine of recognition imply, as we have seen, the acceptance and enforcement by the recognising state of the definitions which the recognised state may have imposed on legal relations—and this, as a rule, even when the definitions so imposed differ from those which are applied to the same legal relations when existing among its own citizens.

The increasing intercourse between individuals of different nations gives a growing importance to the interests affected by this branch of law—the rules being accepted and enforced by the various states as part and parcel of their local law. The rights and obligations which result to persons from the possession of immovables are regulated by the law of the country where the immovable subjects are situated. This *lex loci rei sitæ*, as it is called, determines, even in the case of an alien proprietor, all questions relating to the acquisition of immovables, whether by sale or prescription, to letting, hiring, and mortgaging, working of mines and minerals, servitudes, and to all taxes and public burdens. The law of the place where real property is situated in short governs exclusively as to the tenure, the title, and the descent of such property. In nearly all European countries the rule long obtained that the tenure of immovable property was only possible to a foreigner on the condition of political naturalisation. In almost all states this rule has now been relaxed; and in Britain it has been entirely departed from. The British Nationality and Status of Aliens Act, 1914, sect. 17, provides: 'Real and personal property of every description may be taken, acquired, held, and disposed of by an alien in the same manner in all respects as by a natural-born British subject; and a title to real and personal property of every description may be derived through, from, or in succession to an alien, in the same manner in all respects as through, from, or in succession to a natural-born British subject.' It is, however, expressly provided that this section shall not operate so as to qualify an alien to be the owner of a British ship. As regards movable or personal property, the general rule is *mobilia sequuntur personam*; that is to say, rights to movables are regulated by the law of the owner's domicile (*lex domicilii*). The modern tendency is to substitute political nationality for domicile as the test of personal law; but, as between two jurisdictions comprised in one state, such as England and Scotland, such a substitution is not possible, and there at least the *lex domicilii* must maintain its ground. Every one at the moment of birth acquires a domicile of origin, which, in the case of legitimate children, is the domicile of their father, and, in the case of illegitimate children, that of their mother. This domicile is retained until another takes its place. A domicile of origin may be abandoned and another acquired by choice. In order to effect this, there

must be not merely change of residence but proof of an intention to change domicile. A woman, on her marriage, takes the domicile of her husband; but a change of domicile *stante matrimonio* does not alter rights set up by marriage-contract, express or implied. The law of the domicile also regulates questions regarding status, legal capacity, legitimacy, and succession to movable property. The construction, incidents, and validity of a contract are ruled by the law which the parties intended. *Prima facie* the law of the country where the contract was made (*lex loci contractus*) will be applied. If, however, the contract is to be wholly performed in a country different from the *locus contractus*, the law of the place of performance (*lex loci solutionis*) will govern. As regards the contract of marriage, if a marriage is valid by the law of the place where it is made it is valid everywhere. Questions as to the competency and value of evidence, or as to procedure, or as to the admissibility of prescriptions and limitations, are determined by the law of the place where the action is raised (*lex fori*). The ascertainment of foreign law is dealt with as a question of fact to be settled on evidence.

Interpleader is a form of process in the English courts intended for the protection of a defendant who claims no interest in the subject-matter of a suit, while at the same time he has reason to know that the plaintiff's title is disputed by some other claimant. In such a case the defendant may apply to a judge, who will order the plaintiff and the other claimant to appear and interplead. The stakeholder himself may now initiate an interpleader. Special protection is given to sheriffs, &c., when goods taken in execution are claimed by a third party.

Interpretation. See EXEGESIS.

Interpreter. See DRAGOMAN.

Interval, in Music, is the difference of pitch between any two musical tones. Since pitch depends upon the vibration-frequencies, the relation between any two pitches is the numerical ratio between the two vibration-frequencies; and all pairs of tones within which the frequencies have the same ratios present equal intervals. The interval between any two tones, whether chosen or heard at random, is thus expressible as an arithmetical ratio; but musically it is only certain intervals which are recognised as being musical intervals, and what these are depends upon the Scale (q.v.) which is in use. Among the European nations and those of European descent the diatonic scale is employed; and this, when unmodified by Temperament (q.v.), presents the ratios given under Harmonics (q.v.). Within such a scale the various intervals that may be found are (C being taken to represent the keynote of the scale) minor second (= E—F or B—C') = 16/15; grave major second (= D—E or G—A) = 10/9; major second (= C—D, F—G, A—B) = 9/8; grave minor third (= D—F) = 32/27; minor third (= E—G, A—C', B—D') = 6/5; major third (= C—E, F—A, or G—B) = 5/4; perfect fourth (= C—F, D—G, E—A, G—C', or B—E') = 4/3; acute fourth (= A—D') = 27/20; acute augmented fourth (= F—B) = 45/32; grave diminished fifth (= B—F') = 64/45; grave fifth (= D—A) = 40/27; perfect fifth (= C—G, E—B, F—C', G—D', A—E') = 3/2; minor sixth (E—C', A—F', B—G') = 8/5; major sixth (= C—A, D—B, G—E') = 5/3; acute major sixth (= F—D') = 27/16; grave minor seventh (D—C', G—F', B—A') = 16/9; minor seventh (E—D', A—G') = 9/5; seventh (C—B, F—E') = 15/8; octave (C—C', D—D', &c.) = 2/1. By taking various notes of the diatonic scale as starting-points, and measuring known intervals from these, we arrive at intermediate notes of the scale, of which the following are examples, the vibration-ratios being given with reference to C:

	Vibration-ratios.
C♯, minor third below E.....	25/24 = 1.0416
D♭, (as A:D::A♭:D♭).....	27/25 = 1.0800
D♯, minor second below E.....	75/64 = 1.1672
E♭, minor third above C.....	6/5 = 1.2000
A♭, minor sixth above C.....	8/5 = 1.6000
B♭, minor seventh above C.....	9/5 = 1.8000
B♯, 3 major thirds above C.....	125/64 = 1.9531

The difference of pitch between C and C♯ or between D and D♭ is frequently called a semitone, and an interval increased or diminished by a semitone is said to be augmented or diminished. This applies especially to the intervals of a fourth and a fifth, which with the octave are said to be perfect, because any augmentation or diminution mars their consonance. The major sixth or third may, however, be diminished to a 'minor' sixth or third without destroying the consonance; and the term 'minor' is also applied to the diminished second or seventh. The octave begins a new series, and thus the 'ninth' is the octave of the second, and so forth. For further discussion of the musical nomenclature, which is somewhat unsettled, see article 'Interval' in Grove's *Dictionary of Music and Musicians*; and for a numerical table of the various intermediate tones within the scale, see Daniel's *Principles of Physics*, 4th ed. pp. 426-27.

Intestacy, the state of a person who has died without testing—i.e. without leaving a will. If no will, or deed equivalent to a will, is executed, or if a will executed is invalid from defect of form, then an intestacy occurs, and the law provides an heir or next-of-kin, in lieu of the owner himself doing so. See HEIR, HUSBAND AND WIFE.

Intestines, a part of the digestive system, divided into the smaller intestine (comprising duodenum, jejunum, and ileum) and the greater intestine. See DIGESTION, GUT; and for Diseases, see CONSTIPATION, DIARRHEA, DYSENTERY, ENTERITIS, PERITONITIS, &c.

Intimidation. See THREAT.

Intonation, the opening phrase of any plain-song melody, sung usually either by the officiating priest alone, or by one or more selected choristers. The term is most commonly applied to the first member (consisting of two or three notes) of a Gregorian Psalm-tone, the other members of it being the *dominant* (or reciting-note), the *mediation*, and the *ending*. Its use is confined usually to the first verse of the psalm or canticle, except in the case of the *Magnificat*, *Benedictus*, and *Venite*, to give greater solemnity to which it recurs in each successive verse. See also TEMPERAMENT.

Intoning, a modern popular term for the utterance in musical recitative of the versicles, responses, collects, &c., of the Anglican Liturgy. This recitative consists mainly of a single sustained note, or *monotone*, but may be varied by the introduction of certain simple inflections, which have the sanction of more or less prevalent custom or tradition.

Such musical recitative in vocal prayer is undoubtedly very ancient, and its employment in Christian worship is, in fact, an inheritance from the Synagogue, where it may be heard still. It obtains equally among Mohammedans, American Indians, South Sea Islanders, and the great majority of barbarous nations, and would seem to be the outcome of an instinctive feeling that the familiarity of our colloquial tones of voice is out of keeping with the reverence that befits human intercourse with Deity. Whatever may be said for or against the practice elsewhere, there can be no doubt that in our cathedrals and larger sacred buildings an audible utterance would without it be far less easily attainable.

Intoxication. This term is applied to the condition brought about by an overdose of alcohol. The symptoms induced vary a good deal according to the rapidity with which the alcohol is drunk and absorbed into the blood, and also according to the form—spirits, wine, or beer—in which it is taken. If they are swallowed rapidly in large quantities the symptoms are those of a narcotic poison. See ALCOHOL, ALCOHOLISM, POISON.

Intoxication, or drunkenness, is, in point of law, no excuse for any wrong done by the drunken party. Crimes which are committed in a state of drunkenness are punishable in the same way as if the actor were sober, though it is discretionary in the court to mitigate the sentence. A contract made when the parties, or either of them, are in a state of complete incapacity from intoxication may be made void. So it is when one of the parties is intoxicated, and a sober person induces his consent by fraud. Thus, if goods are sold to a person so drunk that he does not know what he is doing, the purchase may be repudiated as soon as the drunk man becomes sober. Unless he does so immediately on coming to his senses, however, the contract will stand. The drunk man, in short, may either repudiate or enforce the bargain when he comes to his senses. The mere act or state of drunkenness, when privately indulged in, is not an offence against the law; but if it be shown in public it may become so. Every person found drunk in a highway or public place, or in a licensed house, is liable to a penalty of ten shillings; and on a second offence within twelve months, to twenty shillings, and on a third offence within twelve months, to forty shillings. To be drunk and riotous, or be drunk while in charge of a horse or carriage, or of a gun,

is punishable with a fine of forty shillings, or imprisonment for one month. Local acts also often impose other penalties. In Scotland several ancient statutes were passed against drunkenness, which, however, are in desuetude. In many local police acts a penalty is imposed on drunkenness in the streets.

Intrenchments. See ENTRENCHMENTS.

Introduction (Ital. *introduzione*), in Music, is a kind of preface or prelude to a following movement. Formerly the introduction was only to be found in large musical works, such as symphonies, overtures, oratorios, &c.; but now it is found in every rondo, fantasia, polonaise, waltz, &c., on the principle that it is considered abrupt to begin all at once, without preparing the audience for what is to come. In earlier operas introduction is applied to the piece of music with which they begin, and which immediately follows the overture. In some cases the overture and introduction are united, the composition going on without any formal pause, as in Gluck's *Iphigénie en Tauride*, Mozart's *Idomeneo* and *Don Giovanni*. Overtures themselves are frequently commenced by an introduction, as in Beethoven's *Egmont* and *Leonora*, Nos. 2 and 3, and Weber's *Freischütz* and *Oberon* overtures. The majority of Wagner's operas commence with an introduction (*Vorspiel* or *Einleitung*), a short one being also prefaced to the second and third acts. The introductions are also important and characteristic parts of several of the symphonies of Beethoven and Schumann.

Introit, in the Roman Catholic Church, an anthem sung at the beginning of the mass, immediately after the *Confiteor*, and when the priest has ascended to the altar. It consists of an antiphon, Gloria Patri, and usually part of a psalm; but other passages of Scripture are used, while a few introits in the present Missal are taken from uninspired writers, and one (Whitsunday) is from 2d Esdras. The introduction of introits is ascribed to Gregory the Great (595), or perhaps to Celestine (423). In the first prayer-book of Edward VI. an introit is prefixed to each collect, consisting of a psalm to be sung after the opening prayer in the communion office.

Intromission, in Scots law, is the assumption of authority to deal with another's property. It is divided into legal and vicious. Legal intromission is where the party is expressly or impliedly authorised, either by judgment or deed, to interfere, as by drawing the rents or getting in debts. Vicious intromission is where an heir or next-of-kin, without any authority, interferes with a deceased person's estate; as, for example, where a person not named by a will, or without the authority of any will, collects the property of the deceased person as if he were regularly appointed. By so doing the vicious intromitter incurs the responsibility of paying all the debts of the deceased.

Intuition, the immediate apprehension by the mind of an object or truth without any process of reasoning or calculation; also any truth held to be thus directly perceived, especially fundamental truths in mathematics, logic, and ethics. Reid (q.v.) and the Scottish school insisted that the mind has a faculty or power of apprehending such truths, which carry conviction with them, are incapable of resolution or analysis, and indefeasible. Intuitionism or intuitionism was combated by Locke, the Mills, Bain, and many modern schools—e.g. utilitarianism. See COMMON SENSE, A PRIORI, KANT, ETHICS, PSYCHOLOGY, SCOTTISH PHILOSOPHY.

Intussusception, or INVAGINATION, is the term applied to the partial displacement of the

bowel in which one portion of it passes into the portion immediately adjacent to it, just as one part of the finger of a glove is sometimes pulled into an adjacent part in the act of withdrawing the hand. In this case the contained portion of intestine is liable to be nipped and strangled by the portion which contains it, and all the danger of Hernia (q.v.) results, with far less chance of successful interference on the part of the surgeon or physician. It is one of the most frequent and fatal causes of obstruction of the bowels in children, but less common in adults. The extent of the intussusception may vary from a fraction of an inch to several feet. The condition, though very dangerous, is not necessarily fatal. If no operation is performed, the invaginated portion may slough, while adhesion is established between the peritoneal surfaces of the upper and lower portions at their places of junction, so that the continuity of the tube is preserved, although a large portion may be destroyed. At an early stage the normal state may sometimes be restored by a large enema; but the proper treatment, when pain, passage of blood, and an abdominal swelling in a child afford a definite diagnosis, is by an operation to pull out and restore or to remove the invaginated part of the bowel.

Inula. See ELECAMPANE.

Inulin, a vegetable principle, isomeric with starch, derived from Elecampane (q.v.).

Invalides, HÔTEL DES. See PARIS.

Invar, an alloy of nickel and steel, valuable for making pendulum rods and measuring appliances, as being practically invariable in dimensions on account of change of temperature.

Inveraray, the county town of Argyllshire, is picturesquely seated on the north-west shore of Loch Fyne, 16 miles SSW. of Dalmally station, and 45 NNW. of Greenock (*viâ* Loch Eck). Removed to its present site in 1742, it has a sculptured stone cross from Iona (c. 1400), and an obelisk to the memory of seventeen Campbells, executed here without trial in 1685 for their share in Argyll's expedition. Inveraray Castle, the seat of the Duke of Argyll (q.v.), was rebuilt in 1744-61. A royal burgh since 1648, Inveraray was till 1918 one of Ayr parliamentary burghs. Pop. (1841) 1233; (1921) 490.

Invercargill, a town in Southland land-district, New Zealand, capital of the county of Southland, stands on an estuary called the New River Harbour, about 100 miles SW. of Dunedin. It is regularly built, with fine wide streets, and is unusually well provided with public parks. Besides the government buildings and schools and churches, it possesses an excellent atheneum and a hospital. There are numerous sawmills in and around the town, besides foundries, flour-mills, breweries, and manufactures of boots, bacon, cordials, &c. There are extensive meat-freezing works at the mouth of the estuary, and much Southland mutton is now sent to England; other exports from Invercargill are wool, grain, cheese, and timber. Pop. (1921) borough, 15,203; with suburbs, 19,210.

Inverkeithing, a royal burgh of Fife, at the mouth of Inverkeithing Bay, 13 miles WNW. of Edinburgh. With Dunfermline, &c., it returns one member to parliament. Pop. (1921) 3350.

Inverlochy, a ruined castle of Inverness-shire, 2 miles NE. of Fort William, near which, on Sunday, 2d February 1645, Montrose completely routed his rival, Argyll.

Inverness, the county town of Inverness-shire, and capital of the northern Highlands, stands on the Ness, near its mouth in the Moray Firth and the north-east end of the Caledonian Canal, 108 miles by rail WNW. of Aberdeen, 144 NNW. of

Perth, and 190 NNW. of Edinburgh. Its wooded environs, hemmed in by hills (Tomnahurich, 223 feet; Torvean, 300; Craighadrick, 430; Dunearn, 940, &c.), form a picturesque and interesting landscape. Visited by Columba (q.v.) about 565, and by Malcolm Canmore made the seat of a royal castle, by Cromwell of a citadel (1652), Inverness has a wealth of memories. It was garrisoned by the English in 1296; in 1411 was burned by Donald of the Isles on his way to Harlaw; and figures repeatedly in the history of the Stuarts, down to their final overthrow at Culloden, hard by. In front of the Scoto-Flemish town-hall (1882), protected now by a fountain, is the Clach-na-Cudain, or 'stone of the tubs,' the palladium of the burgh. The Episcopal cathedral (1867) of the united diocese of Moray, Ross, and Caithness is a fine Decorated edifice; and other features of the place are the county hall (1835) on the site of the castle (not Macbeth's), the infirmary, the lunatic asylum, the royal academy, the barracks, the main suspension bridge (1855), and the Islands, a favourite promenade. Malting, thread-making, and bleaching have given place to woollen manufacture, ship-building, distilling, &c., with considerable shipping and commerce, the harbour having been much improved in 1847 and 1900. The great wool fair (established in 1817) is held in July; and the Northern Meeting (1788) in September. A royal burgh since about 1067, Inverness till 1918 united with Forres, Fortrose, and Nairn to return one member to parliament. Pop. (1831) 9663; (1881) 17,365; (1921) 20,944. Inverness still prides itself, as in Defoe's and Dr Johnson's day, for the purity of its English.

Inverness-shire, a Highland county, the largest in Scotland, and larger than any in England but Yorkshire, stretches from sea to sea, and has a total area of 4323 sq. m., of which 1284 belong to the Hebrides—Skye, Harris, North and South Uist, Benbecula, Barra, Raasay, Eigg, St Kilda, and thirty-seven other inhabited islands. The mainland portion, measuring 85 by 55 miles, is intersected NE. and SW. by the Great Glen and the Caledonian Canal (q.v.). It includes Badenoch, Glenroy, and the valley of the Spey on the east; Lochaber on the south; Glenelg, Glengarry, Arisaig, and Moidart on the west; Strathglass on the north; Glenurquhart and Glenmoriston towards the centre. It is truly a 'land of the mountain and the flood,' for it contains Ben Nevis (4406 feet), the highest point in Britain, with twenty-six other summits exceeding 3500 feet, whilst the chief of its rivers are the Spey, Ness, and Beaul, and of ninety good-sized lakes Lochs Ness, Archaig, Shiel, Lochy, Morar, Laggan, and Eriacht. The west coast is indented by salt-water Lochs Hourn, Nevis, and Moidart. The rocks include gneiss, mica-slate, granite, porphyry, and trap; and the most fertile soil in the country rests on the red sandstone in the valley of the Aird, and between the county town and Beaul. Only 4.6 per cent. of the whole area is in cultivation; and 255 sq. m. are under wood, the rest being sheep-walks, deer-forests, moss, and barren heath, valuable only as grouse-moors. Sheep are the principal live-stock. The rivers and lakes afford splendid fishing. The county returned one member to parliament until 1918, when it became part of the parliamentary county of Inverness and Ross and Cromarty, with three members (one each for Inverness, Ross and Cromarty, and the Western Isles). Inverness is its only town of any size; Kingussie and Fort William, though police burghs, are mere villages, as also are Beaul, Fort Augustus, and Portree. Pop. (1801) 72,672; (1841) 97,799; (1881) 90,454; (1921) 82,455, about 19 inhabitants per square mile. Of these, one-third are in the islands; 43 per cent. speak Gaelic and English;

5.4 per cent. Gaelic only. See articles on the chief islands, lakes, &c., as well as on HIGHLANDS, HEBRIDES, CULLODEN, DEER-FORESTS, GLENROY, and FOYERS.

Inversion, in Music, is of three kinds. (1) Of a chord, when any other of its component notes than the root is placed lowest (see HARMONY). (2) Of an interval (within the octave), when the lower note is transposed an octave higher, or *vice versa*. To find what an interval becomes by inversion, subtract the figure denoting it from the figure nine; thus, a second inverted becomes a seventh, a third becomes a sixth, &c. In this change major intervals become minor, augmented intervals become diminished, and *vice versa*. (3) Of a subject or theme, when it is imitated in contrary motion—i.e. the melody progresses by the same intervals as the original theme, but ascends or descends always in a contrary direction. This is a frequent device in fugues and other contrapuntal music.—In geometry, inversion is the substitution for each point in a figure, of another point, collinear with it and a fixed point (the centre of inversion), the rectangle contained by the distances of the two points from the centre being constant.—In logic, inversion is a form of immediate influence whereby a new proposition (the inverse) is obtained whose subject is the contradictory of that of the original proposition (the invertend).—For inversion in chemistry, see DIGESTION, POLARISATION, SUGAR, FERMENTATION.

Invertebrata, a collective title for those animals which agree in *not* exhibiting the characteristics of Vertebrates—viz. a dorsal nerve cord, a dorsal median supporting axis or notochord, respiratory clefts on the pharynx, a ventral heart, and eyes arising for the most part as outgrowths of the brain. But the dividing line is no longer so clear as it once seemed, for not only are Ascidians or Tunicata recognised as degenerate Vertebrate animals, but several remarkable type-forms—e.g. Balanoglossus (q.v.) and Cephalodiscus (q.v.)—are so near the boundary line that they are usually called Hemichordata or half Vertebrates.

Invertebrate animals include the unicellular Protozoa, the Sponges or Porifera, the Cœlentera or Stinging Animals, many classes of worms, Echinoderms, Arthropods (Crustaceans, Insects, Arachnids, &c.), Molluscs, and some less familiar divisions.

Inverurie, a royal burgh of Aberdeenshire, at the influx of the Urie to the Don, 16 miles NW. of Aberdeen. With Elgin, &c., it returned one member to parliament till 1918. Pop. 4500.

Investiture, in feudal and ecclesiastical history, means the act of giving corporal possession of a manor, office, or benefice, accompanied by a certain ceremonial, such as the delivery of a branch, a banner, or an instrument of office, more or less designed to signify the power or authority which it is supposed to convey. The contest about ecclesiastical investitures is interwoven with the whole course of mediæval history. The system of feudal tenure had become so universal that it affected even the land held by ecclesiastics. Accordingly, ecclesiastics who, in virtue of the ecclesiastical office which they held, came into possession of lands began to be regarded as becoming by the very fact feudatory to the suzerain of these lands; and the suzerains thought themselves entitled to claim, in reference to these personages, the same rights which they enjoyed over the other feudatories of their domains. Among these rights was that of granting solemn investiture. Now, in the case of bishops, abbots, and other church dignitaries the form of investiture consisted in the delivery of a pastoral staff or crozier, and the placing a ring upon the finger; and as these badges of office were emblematic—the one of

the spiritual care of souls, the other of the espousals, as it were, between the pastor and his church or monastery—the assumption of this right by the lay suzerains became a subject of constant and angry complaint on the part of the church. On the part of the suzerains it was replied that they did not claim to grant by this rite the spiritual powers of the office, their function being solely to grant possession of its temporalities. But the church party urged that the ceremonial in itself involved the granting of spiritual powers; inasmuch that, in order to prevent the clergy from electing to a see when vacant, it was the practice of the emperors to take possession of the crosier and ring, until it should be their own pleasure to grant investiture to their favourites. The disfavour in which the practice had long been held found its most energetic expression in the person of Gregory VII., who having, in the year 1074, enacted most stringent measures for the repression of simony, proceeded, in 1075, to condemn, under excommunication, the practice of investiture, as almost necessarily connected with simony, or leading to it. But a pope of the same century, Urban II., went further, and (1095) absolutely and entirely forbade not alone lay investiture, but the taking of an oath of fealty to a lay suzerain by an ecclesiastic. In the 12th century the pope, Pascal II., agreed to surrender the possessions and royalties of the church on condition of the emperor (Henry V.) giving up his claim to investiture. This treaty, however, never had any practical effect; nor was the contest finally adjusted until the celebrated concordat of Worms in 1122, in which the emperor agreed to give up the form of investiture *with the ring and pastoral staff*, to grant to the clergy the right of free elections, and to restore all the possessions of the Church of Rome which had been seized either by himself or by his father; while the pope, on his part, consented that the elections should be held in the presence of the emperor or his official, but with a right of appeal to the provincial synod; that investiture might be given by the emperor, but only *by the touch of the sceptre*; and that the bishops and other church dignitaries should faithfully discharge all the feudal duties which belonged to their principality. See ENGLAND (CHURCH OF), FEUDALISM.

Invincibles. See FENIANS, CAVENTISH.

Involucre. In a shortened inflorescence (q.v.), such as the umbel, the bracts, unless suppressed, are necessarily close together, and form an apparent whorl (but really a close spiral) around the group of pedicels. This is the involucre. In compound umbels the whorl of bracts of the secondary umbel is therefore a secondary involucre, and is commonly called an involucrel. In composites the crowded whorl of green leaves immediately outside the capitulum, which the non-botanist mistakes for a calyx, is constantly termed the involucre, but no less inaccurately, since here the true bracts are those of the separate florets, and occur on the surface of the capitulum itself (e.g. *Finnia*, Sunflower, &c.). The composite 'involucre' is therefore merely derived from those leaves of the axis below the capitulum which remain green and vegetative since bearing no florets in their axils. In Scabious (q.v.) the true bract of each floret in the capitulum unites as a sheath around the ovary, and is also known as the involucrel. Here, again, we have a regrettable use of terms, themselves hardly necessary, in two distinct senses.

Involute. See EVOLUTE.

Involution and Evolution are two operations the converse of each other. The object of the first is to raise a number to any power, which is effected by continuously multiplying the number

by itself till the number of factors is equal to the number designating the power. Thus, 2 raised to the *third* power is $2 \times 2 \times 2$, or 8; 7 raised to the *fourth* power is $7 \times 7 \times 7 \times 7$, or 2401, &c. Evolution, on the other hand, is the extraction of a root of any number—that is, it is a method for discovering *what* number, when raised to a certain power, will give a certain known number. Thus, the square root of 64 is 8—that is, 8 is the number which, raised to the second power, will give 64; 3 is the fourth root of 81—that is, 3 raised to the fourth power is 81; and so on. The symbols expressive of the two operations are as follow: 5^2 means that 5 is to be raised to the third power; $(7^2)^5$ means that the square or second power of 7 is to be raised to the fifth power; $\sqrt{9}$ or $\sqrt[2]{9}$ or $9^{\frac{1}{2}}$ signifies that the extraction of the second or square root of 9 is required; $\sqrt[4]{256}$ or $256^{\frac{1}{4}}$, that the fourth root of 256 is to be extracted; and so on. Involution and evolution, like multiplication and division, or differentiation and integration, differ in the extent of their application; the former, or direct operation, can always be completed, while there are numberless cases in which the latter fails to express the result with perfect accuracy.

Io, the daughter of Inachus, king of Argos, was beloved by Zeus, and, transformed through fear of Hera's jealousy into a cow, had many wanderings. See ARGUS.

Iodine (I; atom. wt. 126.97; atom. number 53) is one of the halogen elements. It was discovered in 1811, by Courtois, in the waste liquors produced in the manufacture of carbonate of soda from the ashes of seaweeds. A few years later Gay-Lussac discovered that it was a simple elementary body. While it is still obtained from the half-fused ash of dried seaweeds, which is known in Britain as Kelp (q.v.), it is much more largely prepared in South America from the iodate of sodium, which is found associated with nitrate of sodium in the native Chile saltpetre.

In small quantity, and usually in combination with sodium, magnesium, or calcium, iodine is very widely diffused over the earth's surface. It exists in sea-water, in marine animals and plants, and in certain mineral springs. It is also found in several minerals, as, for example, in certain Mexican silver ores, in Silesian zinc ores, in phosphorite from the Upper Palatinate, and in coal.

At ordinary temperatures it usually occurs in solid, dark-gray, glistening scales; it is, however, crystallisable, and sometimes appears as an octahedron with a rhombic base. It is soft, and admits readily of trituration, has the high specific gravity of 4.95, and evolves a peculiar and disagreeable odour, which indicates its great volatility. It fuses at 225° (107° C.), and at about 350° (177° C.) it boils, and is converted into the purple vapour to which it owes its name (Gr. *iōdēs*, 'violet-like'); it has an acrid taste, and communicates a brownish-yellow colour to the skin. It is very slightly soluble in water, but dissolves readily in watery solutions of iodide of potassium and of hydriodic acid, and in alcohol and ether. Iodine vapour is the heaviest of known vapours, its specific gravity compared with air as unity being 8.716. It combines directly with phosphorus, sulphur, and the metals. Its behaviour with hydrogen is analogous to that of chlorine and bromine (see HYDROCHLORIC ACID), but its affinities are weaker than those of the last-named elements. It likewise combines with numerous organic substances, and the compound which it forms with starch is of such an intense blue colour that a solution of starch forms the best test for the presence of free iodine. By means of this test one part of iodine may be

detected when dissolved in one million parts of water.

With hydrogen iodine forms one compound, *hydriodic acid* (HI), a colourless, pungent acid gas, which in most respects is analogous with hydrochloric acid. It may be obtained by gently heating a mixture of amorphous phosphorus, iodine, and water. The soluble iodides of the metals may be obtained by the direct combination of the metal and iodine in presence of water. Some of the insoluble iodides are of extreme brilliancy—e.g. the iodide of mercury, scarlet; the iodide of lead, yellow; and others are of great value in medicine. Amongst the latter must be especially mentioned iodide of potassium, iodide of iron, and the iodides of mercury.

Iodide of potassium is one of the most important medicines in the pharmacopœia. It crystallises in colourless cubes, which are sometimes clear, but usually have an opaque whitish appearance, and are soluble in water and spirit. It is decomposed and the iodine set free by chlorine, bromine, fuming nitric acid, and Ozone (q.v.). Iodide of iron is formed by shaking iron wire or filings in a closed vessel with four times the weight of iodine suspended in water. There are two iodides of mercury—viz. the green sub-iodide (HgI) and the red iodide (HgI₂). There are several well-defined compounds of iodine and oxygen, but they are of no special interest.

The preparations of iodine are employed extensively in medicine and in Photography (q.v.). Iodine itself or its compounds may give rise to the symptoms known as *iodism*; most commonly running at the nose and eyes, with headache and sore throat; sometimes irritation of the intestinal canal, either alone or combined with the other symptoms. In the case of the iodine compounds these unpleasant results usually cease if the dose be increased.

Iodine and its compounds increase the activity of the absorbent system generally, and are useful in enlargement of the glands connected with that system (lymphatic glands, thyroid, spleen), and wherever absorption is deficient (hypertrophy of breasts, uterus, &c.; indolent inflammatory exudation in any organ). But they are perhaps of the greatest value in certain forms of chronic rheumatism, certain stages of syphilis, in scrofulous conditions generally, and in chronic poisoning by mercury and lead. In the last case they set free the metals from insoluble compounds in the tissues, and allow them to be eliminated from the body in solution in the urine.

Iodine is chiefly prescribed internally in combination, as iodide of potassium, iodide of iron, especially in strumous cases, and red iodide of mercury in syphilis. Free iodine is very apt to cause irritation of the intestinal canal, and can in general only be employed in small doses. But as an external application, in the form of ointment, tincture, or liniment, it is extensively used and is very valuable. The tincture is used in surgery as an antiseptic. It acts as a parasiticide in ringworm, removes muscular pains, and promotes the absorption of exudations and the subduing of chronic inflammations. In large doses iodine and most of the iodides act as irritant poisons; but very few fatal cases are on record. In the event of poisoning with the tincture of iodine the first point is to evacuate the stomach. See POISONS.

Iodoform (CHI₃) is a lemon-yellow crystalline substance, having a saffron-like odour and an unpleasant iodine-like taste. Its odour is most persistent, and can hardly be removed. It is of interest as having a composition similar to that of Chloroform (q.v.), from which it only differs in having iodine in the place of chlorine. It is now

prepared by an electrolytic process. It may be prepared by the action of iodine on alcohol in the presence of carbonate of potash. It is almost insoluble in water, but dissolves in alcohol, ether, and chloroform. It is readily volatile when heated, and in the form of vapour has anæsthetic properties. It is employed externally in powder, ointment, or in its solution in collodion, as an application to painful ulcers; and it is of great value in many departments of antiseptic surgery.

Iola, a city of Allen county, Kansas, 100 miles S. by W. of Kansas City. It is in the midst of a rich natural gas valley, and has important manufactures of cement and sulphuric acid, and large zinc smelters and rolling-mills. Pop. 8500.

Iolite. See CORDIERITE.

Iona, the most famous of the Hebrides, 1½ mile W. of the south-western extremity of Mull. Its modern name is believed to have originated in a mistaken reading of *n* for *u*; the word in the oldest manuscripts being clearly written *Iova*. From the 6th century to the 17th century the island was most generally called *I*, *Ii*, *Ia*, *Io*, *Eo*, *Hy*, *Hi*, *Hii*, *Hie*, *Hu*, *Y*, or *Yi*—that is, simply, 'the island'; or *Icolmkill*, *I-Columb-Kille*, or *Hu-Colum-Kille*—that is, 'the island of Columba of the church.' It is 3½ miles long, and 1½ mile broad. Its area, computed by Bede at 'five families' (or 'five hides of land,' as the passage is rendered in the Anglo-Saxon Chronicle), is 3½ sq. m., or 2264 acres. The soil is naturally fruitful; its fertility was regarded as miraculous in the dark ages, and, no doubt, led to the early occupation of Iona. Dunii, the highest point of the island, is 330 feet above sea-level. Pop. 200.

Its history begins in the year 563, when St Columba (q.v.), leaving the shores of Ireland, landed upon Iona with twelve disciples. Having obtained a grant of the island, he built upon it a monastery, which was long regarded as the mother-church of the Picts, and was venerated not only among the Scots of Britain and Ireland, but among the Angles of the north of England, who owed their conversion to the self-denying missionaries of Iona. From the end of the 6th to the end of the 8th century Iona was scarcely second to any monastery in the British Isles; and it was this brilliant era of its annals which rose in Johnson's mind when he described it as 'that illustrious island which was once the luminary of the Caledonian regions, whence savage clans and roving barbarians derived the benefits of knowledge and the blessings of religion.' But neither piety nor learning availed to save it from the ravages of the fierce and heathen Norsemen. They burned it in 795 and again in 802. Its 'family' (as the monks were called) of sixty-eight persons were martyred in 806. A second martyrdom, in 825, is the subject of a contemporary Latin poem by Walafridus Strabus. On the Christmas evening of 986 the island was again wasted by the Norsemen, who slew the abbot and fifteen of his monks. Towards the end of the next century the monastery was repaired by St Margaret, the queen of Malcolm Canmore. It was visited in 1097 by King Magnus Barefoot of Norway. It was now part of that kingdom, and so fell under the ecclesiastical jurisdiction of the Bishop of Man and the Archbishop of Trondhjem. In 1206 a Benedictine monastery was founded here, and a Benedictine (afterwards Augustinian) nunnery, in 1506 Iona became the seat of the Scottish Bishop of the Isles, the abbey church being his cathedral, and the monks his chapter.

No building now remains on the island which can claim to have sheltered St Columba or his disciples. The most ancient ruins are the Laithrichean, or Foundations, in a little bay to the

west of Port-a-Churraich; the Cobhan Cuidich, or Culdees' Cell, in a hollow between Dunii and Dunbhuirg; the rath or hill-fort of Dunbhuirg; and the Gleann-an-Teampull, or Glen of the Church, in the middle of the island. St Oran's Chapel, now the oldest church in the island, may probably be of the later part of the 11th century. St Mary's Nunnery is perhaps a century later. The Cathedral, or St Mary's Church (c. 1203), whose ruin was in 1899 given by the Duke of Argyll to the Church of Scotland, and since 1902 restored, has a choir with north sacristy and south chapels; north and south transepts; central tower (70 feet); and a nave. An inscription implied that it was the work of an Irish ecclesiastic who died in 1203. On the north of the cathedral are the chapter-house and other remains of the conventual or monastic buildings. Facing the cathedral door is St Martin's Cross. Maclean's Cross stands by 'the Street of the Dead.' In the 'Reilig Oran'—so called, it is supposed, from St Oran, a kinsman of St Columba, the first who found a grave in it—were buried Ecgfrid, king of Northumbria, in 684; Godfred, king of the Isles, in 1188; and others. No monuments of these princes now remain. The oldest of the many tombstones on the island are two with Irish inscriptions, one of them, it is believed, being the monument of a bishop of Connor who died at Iona in 1174.

Ionian, the ancient name of the coast districts and islands of western Asia Minor. The name was derived from the Ionians, one of the four most ancient tribes in Greece. According to the usually received tradition, after being driven out of the Peloponnesus, they removed to Attica, whence, about 1060 B.C., they sent forth warrior bands to settle on the bays and promontories and islands of Asia Minor; but it is more probable that the immigration was gradual and was spread over a long period of time. Although mountainous, Ionia embraced the three valleys watered by the Hermus, Cayster, and Meander, and was a beautiful and fertile country, extending, according to Ptolemy, from the river Hermus to the river Meander, though Herodotus and Strabo make it somewhat larger. It soon reached a high point of prosperity; agriculture and commerce flourished; colonies were sent out, which settled on the shores of the Black Sea and in the south of Gaul (Masilis); and great cities arose, of which Ephesus, Smyrna, Clazomenae, Erythrae, Colophon, and Miletus were the most celebrated. These cities, with six others, formed the Ionian League. Each retained its independence, the form of government being democratical; but all met together periodically at Panionium, near Priene, for the discussion of such affairs and interests as they had in common, for religious worship, and for the celebration of athletic games. A few centuries later the twelve cities were made thirteen by the accession of Smyrna. These Ionian states were gradually subdued by the kings of Lydia. Then they passed (557 B.C.) under the sway of the Persians, but were allowed a considerable measure of internal liberty. They revolted, however, in 500, but were reduced to subjection after a bloody battle near Ephesus in 496 B.C. During the great Persian war the contingent which they furnished to their oriental masters deserted to the Greeks at the battle of Mycale (479 B.C.); thereupon the Ionians entered into an alliance with Athens, upon which they now became dependent. By the peace of Antalcidas (387 B.C.) they were again made subject to the Persians, and remained so till the time of Alexander the Great. From this period Ionia shared the fate of the neighbouring countries, and in 64 B.C. was added to the Roman empire by Pompey, after the third Mithridatic war. In later times it was so ravaged by the Turks that few traces of

its former greatness are now left.—The Ionians were regarded as somewhat effeminate. They were wealthy and luxurious; and the fine arts were cultivated amongst them at a much earlier date than amongst their kinsmen in the mother-country. Two of the celebrated temples of the Greek world, that of Diana and that of Apollo, both near Ephesus, were in Ionia. For Ionic architecture, see GREEK ARCHITECTURE. For the Ionian mode, see HARMONY. The Ionian School was the name given to the representative philosophers of the Ionian Greeks, such as Thales, Anaximander, Anaximenes, Heraclitus, Anaxagoras (see these names), who devoted themselves mainly to the question what was the primordial constitutive principle of the cosmical universe. The Ionic dialect, nearly akin to Attic, excels the other Greek dialects in softness and smoothness, chiefly from the greater richness of its vowel-system.

Ionian Islands, a group, or rather chain, of islands on the west and south coasts of Greece, may be divided into three groups: Corfu (Kerkyra), Paxo, and some smaller islands are the northernmost; then come Leukas (Leukadia, Levkas, or Santa Maura); Cephalonia (Kephallenia), Zante (Zakynthos), and Ithaca; and in the south Cythera (Cerigo). Accounts of their physical features and other particulars will be found under the separate islands. Total area, 1000 sq. m.; pop. about 260,000, the great majority of Greek descent. The surface is generally mountainous, the plains and valleys being fertile. The collective term 'Ionian' is of modern date. Previous to the subjugation of Greece by Rome the only one of these islands that rose above the historic horizon was the Corinthian colony of Coreyra. On the division of the Roman empire these islands were included in the eastern half. In 1081 Corfu and Cephalonia fell into the hands of Robert Guiscard, and from that time they had a very chequered history for three hundred and twenty years. In 1401 Corfu came into the possession of the Venetians, who in the same century acquired Zante and Cephalonia, and subsequently most of the other islands included in the group. The Venetians retained them until 1797, when they ceded them to France. The islands were seized by Russia and Turkey in 1799; and the Emperor Paul created the Republic of the Seven United Islands, under the protection of Turkey. But in 1807 they were given back to France by the treaty of Tilist. In 1809 Great Britain seized Zante, Cephalonia, and Cerigo, in 1810 Santa Maura, in 1814 Paxo, and after Napoleon's fall Corfu; and on November 5, 1815, were formed the United States of the Ionian Islands, under the protectorate of Great Britain. While they were connected with England the government was carried on by two assemblies and the Lord High Commissioner, the representative of the British government. The rule of the successive commissioners, although directed to the construction of roads, the regulation of the systems of taxation, the establishment of educational institutions, the reform of the administration of justice, and similar public works for the furtherance of the intellectual and material welfare of the people, was on the whole arbitrary and despotic. There was permanent friction, often of a severe character, between the representative of Britain and the representatives of the islanders. Nor did the concessions of freedom of the press, an extension of the franchise, and freedom of election (with the right of the ballot), both municipal and parliamentary, extorted in 1849 by the disturbances of Europe during the year previous, do much to reduce the friction. Insurrections broke out amongst the peasantry; the discontent with British rule increased; and the party that agitated

for incorporation with Greece waxed daily stronger. In the end of 1858 Gladstone declared against annexation to Greece. But in 1863 the election of the son of the king of Denmark as constitutional king of Greece gave England an opportunity of getting rid of this troublesome dependency. During the Great War Corfu was used as a base where the Serbian armies were able to recuperate and be reorganised after the great retreat. Owing to the murder of the Italian members of the Græco-Albanian Boundary Commission Italy bombarded and occupied Corfu in August 1923, and only after the matter had been referred to the Ambassadors' Conference was the affair settled. Greece paid an indemnity of 50,000,000 lire, and Italy evacuated the island on September 27th. The Italian forces had also occupied Paxos, Antipaxos, Samothraki, and Merlera. The islands have now no administrative unity. Cythera (Cerigo) is included in Laconia; the rest fall to the four monarchies of Coreyra, Levkadia, Cephalonia, and Zacynthos.

Ionian Mode. See HARMONY, PLAIN-SONG.

Ionidium, a genus of Violaceæ, tropical and sub-tropical plants. White *ipeacacuanha*, used in the same way as true *Ipeacacuanha* (q.v.), is got from the root of *I. Ipeacacuanha*.

Ions, the components into which an electrolyte is broken up on electrolysis. The one, the Anion (the electro-negative component—e.g. chlorine), travels 'against' the current (in its conventional direction in the circuit), and is deposited on or chemically attacks the anode or positive electrode; the other, the Cation (the electro-positive component—e.g. copper), travels 'with' the current to the cathode—e.g. to the spoons in the plating bath. The name ion is also given to the components of an atom (See ATOM); thus we have negative ions or electrons, and the positive ion made up of one or more small atomic nuclei or protons (See ELECTRON). See also ELECTRICITY. For the ionisation of gases see the end of the same article. See also ATOM, ELECTRON, VACUUM TUBES, SOLUTION.

Iota. See I.

I O U, a memorandum of debt given by a borrower to a lender, so called from being made in this abbreviated form:

LONDON, 1st January 19 .

I O U Twenty Pounds.

To Mr C. D.

A. B.

It is a convenient document, because it requires no stamp, and yet it is valuable evidence of the existence of the debt in case an action is afterwards brought. If, however, the I O U contain any promise to pay the debt, then it will amount to a promissory-note, and be void unless it have a stamp. It should be holograph, but need not be dated, nor addressed to any person, though this is usually done.

Iowa, a state of the American Union, which extends from 40° 36' to 43° 30' N., and from 90° 15' to 96° 38' W., and has an area of 55,475 sq. m. It is bounded on the N. by Minnesota, on the E. by the Mississippi River, on the S. by the state of Missouri, and on the W. by the Missouri and Big Sioux rivers. The climate is continental, with cold winters, hot summers, and sudden changes of temperature. The autumns are beautiful, and of long duration. The mean temperature of the year is 47° F., and the annual rainfall about 33 inches. Iowa is noted for its healthfulness. The surface is a rolling prairie; there are no mountains, and hills or bluffs can only be found along the principal streams. The average eleva-

tion is not far from 900 feet. The highest point (1694 feet) is about 70 miles E. of the north-west corner of the state, and the lowest (444 feet) at the confluence of the Des Moines River with the Mississippi. The soil is unsurpassed in richness and productiveness, all the land being tillable except a few rocky bluffs near the large rivers. Natural forests cover the eastern portion of the state, and there are over 100,000 acres of planted timber. Iowa has also extensive and valuable mineral deposits, as coal, cement, clay, gypsum, lead, limestone, and mineral paints. The coal, which is bituminous, extends over an area of nearly 20,000 sq. m., and in 1920 the production was over 9 million tons. The Mississippi on the eastern and the Missouri on the western border are navigable. To both of these are tributary a number of inland rivers, those of the Mississippi system flowing in a south-easterly and those of the Missouri system in a south-westerly direction. The Upper Iowa, Turkey, Maquoketa, Wapsipicon, Iowa (with its large affluent the Cedar), Skunk, and Des Moines rivers are the principal tributaries of the Mississippi. The rivers of the Missouri system are the Big Sioux, Rock, Floyd's, Little Sioux, Boyer, and Nishnabotony. There are several small lakes in the northern portion of the state, situated principally near the great watersheds.

Iowa is pre-eminently an agricultural state. The nature of the surface offers excellent facilities for the use of agricultural machinery, and makes farming attractive and profitable. In 1921, slightly over four-sevenths of the entire acreage of the state was under the following crops: barley, buckwheat, clover, corn, flax, hay, oats, potatoes, rye, sorghum, sweet potatoes, and wheat. From these, corn and oats gained for Iowa the first place in the Union with 454,000,000 bushels and 154,000,000 bushels respectively. Wheat followed with 10,000,000, while hay and potatoes were important crops. In 1922, there were over seven and a half million hogs, nearly double that of the second state, Illinois. There were also nearly a million dairy cows, and three million other cattle. The state also ranked first with 28,000,000 poultry. While Iowa has good water-power, cheap fuel, and excellent transportation facilities, the development of its manufacturing interests has been but slow. The prosperity of the state depends on, and the chief industries are those connected with, agriculture. Meat and meat products (canned goods), butter, prepared cereal foods, flour, and grist-mill products are the chief. There are also some foundries, and a certain trade in dressed lumber, clay products, and cement. The commerce is chiefly domestic. The principal exports are agricultural and dairy products, coal, gypsum, and lead.

The legislative authority is vested in the general assembly, consisting of two houses, the senate (50 members) and house of representatives (108), and meeting in regular session in January of each even-numbered year. The supreme executive power is vested in a governor, who is elected for a term of two years. The state is divided into ninety-nine counties, and is represented in the national congress by two senators and eleven representatives. The educational policy of the state is most liberal. Schools are established in every district. There are over 13,000 in the state, which claims to have the smallest proportion of illiteracy in the Union, having in 1920 only 1.1 per cent. The State University is at Iowa City, the State Teachers' College at Cedar Falls, the State College of Agriculture and Mechanic Arts at Ames.

The territory of the state of Iowa formed part of the Louisiana Purchase. After Iowa had successively been under the jurisdiction of the territorial governments of Missouri, Michigan, and Wisconsin.

it was organised as a separate territory on the 4th of July 1838, with Burlington as its capital. It had then a population of 22,860. The following year the general assembly located the seat of government at Iowa City. On 28th December 1846 the state was admitted into the Union, with a population of nearly 100,000. In 1856 Des Moines became the permanent capital. Iowa's population in 1850 was 192,214; in 1860, 674,913; in 1870, 1,194,020; in 1880, 1,624,615; in 1890, 1,911,896; in 1900, 2,231,853; and in 1920, 2,404,021. The census of 1920 showed 81 cities and towns of over 2500 inhabitants. Seven of these had over 25,000: Des Moines, 126,468; Sioux City, 71,227; Davenport, 56,727; Cedar Rapids, 45,566; Dubuque, 39,141; Waterloo, 86,230; and Council Bluffs, 36,162.

Iowa City, capital of Johnson county, Iowa, and the seat of the territorial and state government from 1839 to 1856, is situated on the Iowa River, 120 miles by rail E. of Des Moines. The old capitol is now the home of the state university. There are manufactures of flour, iron goods, chairs, threshers, &c., and is the centre for a rich farming and stock-breeding district. Pop. (1920) 11,267.

Ipecacuanha, the name both of a very valuable medicine and of the plant producing it. The plant (*Cephaelis*, or *Uragoga*, *Ipecacuanha*) belongs to the order Rubiaceæ, and is a native of the damp shady woods in Brazil and some other parts of

Ipecacuanha (*Cephaelis Ipecacuanha*) in flower;
a, the root.

South America. More recently it has been cultivated in India and Ceylon, although there is a tendency under cultivation for the plant to run into varieties. It is somewhat shrubby, with a few oblongo-lanceolate leaves near the ends of the branches, long-stalked heads of small white flowers, and soft dark-purple berries. The part of ipecacuanha used in medicine is the root, which is simple or divided into a few branches, flexuous, about as thick as a goose-quill, and is composed of rings of various size, somewhat fleshy when fresh, and appearing as if closely strung on a central woody cord. Ipecacuanha root is prepared for the market by mere drying. It is collected at all seasons, although chiefly from January to March. The plant is never cultivated in Brazil. It has now become scarce in the neighbourhood of towns, but, owing to the readiness with which it is propagated from portions of the root, it is not likely to be exterminated.

It is in the bark of the root that the active principle, the *emetine*, almost entirely lies; the other ingredients, such as fatty matters, starch, lignine, &c., being almost inert. Emetine is represented by the formula $C_{20}H_{29}N_2O_8$. It is a white, inodorous, and bitter powder, moderately soluble in alcohol, and having all the characters of the vegetable alkaloids. It acts as a violent emetic in

doses of $\frac{1}{16}$ th of a grain or less, and is a powerful poison. In good specimens of root it is present to the extent of nearly 1 per cent. In small and repeated doses—as, for instance, of a grain or less—ipecacuanha increases the activity of the secreting organs, especially of the bronchial mucous membrane, and of the skin. In larger doses of from 1 to 5 grains it excites nausea and depression; while in doses of from 15 to 30 grains it acts as an emetic, without producing such violent action or so much nausea and depression as tartar emetic. Ipecacuanha is useful as an emetic when it is necessary to unload the stomach in cases where there is great debility, or in childhood. As a nauseant, expectorant, and diaphoretic it is prescribed in affections of the respiratory organs, as catarrh, whooping-cough, asthma, &c.; in affections of the alimentary canal, as indigestion and dysentery; and in disorders in which it is desired to increase the action of the skin, as in diabetes and in febrile affections.

Besides the Powder, the most useful preparations are the Wine of Ipecacuanha—of which the dose to an adult as a diaphoretic and expectorant ranges from 10 to 40 minims, and as an emetic from 2 to 4 drachms—and the Compound Ipecacuanha Powder, commonly known as *Dover's Powder* (q.v.). See also ASCLEPIAS, VIOLACEÆ.

Ipek. See **PEÇ.**

Iphicrates (419–353 B.C.), an Athenian general, who served in the Corinthian war (395–387), in Egypt (379–374), and against Sparta (372–371).

Iphigeni'a, in Greek legend, a daughter of Agamemnon and Clytemnestra, or, according to others, an adopted daughter of Clytemnestra. Her father, having offended Artemis, could only avert the wrath of the goddess by promising to sacrifice to her the most beautiful thing born within the year. This happened to be Iphigenia. When Iphigenia was brought to the altar, however, she disappeared, and a hind lay there in her stead; Artemis herself carried her off in a cloud to Tauris (Crimea), where she became her priestess, but was afterwards recognised by her brother Orestes, who took her, along with the image of Artemis, to Attica. The legend is of post-Homeric origin, but evidently goes back to the barbaric stage of the Greek religion, when human sacrifices were wont to be made on solemn occasions. It gave a subject to painters, sculptors, and poets, and is imperishably enshrined in two splendid tragedies of Euripides. In modern art it has employed the genius of Gluck and Strauss in music, and of Racine and Goethe in poetry.

Ipomœa, a genus of plants of the natural order Convolvulacæ, differing very little from the genus Convolvulus (q.v.). Some botanists include in this genus a number of plants which others distribute over six or seven separate genera: *Exogonium* (see JALAP), *Batatas* (see SWEET POTATO), *Quamoclit*, *Calonyction*, &c. In any case the species run to some hundreds, mostly climbing plants of warm and tropical climates. Some are creeping plants, such as *I. pes-capræ* (or *I. biloba*), a characteristic sand-binder of tropical shores. *I. chrysorrhiza* has served a similar purpose in New Zealand. Some species are cultivated in gardens for the sake of their flowers, such as *I. purpurea* and others, which share with it the name of Morning Glory. Of species used as sources of purgatives, besides Jalap (*I. Purga*), *I.* (or *Operculina*) *Turpethum* yields turpeth; while Mexican scammony made from the roots of *I. orizabensis*, a native of the Mexican Mountains, has similar properties to the true Scammony (q.v.), and has come to be used instead of it.

Irish Miles

Ipswich, a county borough of Suffolk, 69 miles NE. of London by rail, is situated on the side of a hill on the left bank of the river Gipping, which, here taking the name of the Orwell, becomes tidal, and after a south-easterly course of 12 miles more falls into the German Ocean at Harwich. In the older portions of the town, principally grouped near the river, the streets are narrow and irregularly built, and still retain many picturesque old buildings, decorated with carved work, such as Sparrowe's House (1567), the Neptune Inn (1639), Archdeacon's Place (1471), and Wolsey's Gateway (1528). Of public buildings the principal are a town-hall (1868), in the Italian Renaissance style of architecture; post-office (1881), and corn exchange (1882), both close by and in the same style; public hall (1868); museum and school of art, the first of which, founded in 1847, is notable for its splendid collections of Suffolk Crag fossils and British birds; custom-house (1845); mechanics' institute (1824); hospital (1835-69-77), and barracks. The churches are numerous, mostly built of flint, and in the Perpendicular style, having as the principal or 'metropolitan' church St Mary Le Tower, with a tower and spire 176 feet high, and a fine peal of twelve bells. A bishopric of St Edmundsbury and Ipswich was established in 1913, and the bishop's residence is at Ipswich. Of educational establishments the principal is the grammar-school, dating from at least 1477, reorganised by Queen Elizabeth in 1565. Near it are two arboretums, charmingly laid out, and Christchurch Park, with its fine Tudor mansion (1549). The dock, opened in 1842, covers 30 acres, and is approached from the Orwell by an entrance lock (1881) capable of admitting vessels of 1400 tons. The principal manufactures are those of agricultural implements, railway plant, artificial manures, and clothing. In the history of Ipswich the chief events deserving mention are its pillaging in 991 and 1000 by the Danes; the granting in 1199 of its first charter by King John; visitations of the plague (1603 and 1666); partial destruction by fire (1654); and visits of Elizabeth (1561 and 1565). Cardinal Wolsey was a native. Gainsborough the painter was a resident. Ipswich returned two members to parliament from 1447 to 1918, and since then one. Its population in 1801 only 11,336, had risen in 1881 to 50,546, and in 1921 to 79,383.

Ipswich, a town of Queensland, on the river Bremer, 23 miles W. of Brisbane by rail. It stands in a rich coal-mining district. Pop. with suburbs (1921) 20,517.

Iquique, the port and capital of the Chilean territory of Tarapacá (Peruvian till 1881). It exports saltpetre, borax, and iodine. The climate is hot, and drinking-water has to be obtained by distillation. Earthquakes have more than once damaged the town, of which one of the most serious was that of November 1922. The roadstead is safe, and a mole has been built. Pop. 40,000.

Iquitos, capital of the Peruvian department of Loreto, on the left bank of the Marañon (Amazon), about 75 miles above the mouth of the Río Napo. It has an active trade by river; the imports are exchanged mostly for india-rubber. Pop. 20,000, mostly Indians and half-castes.

Iran, or **ERAN**, originally the name applied to the great Asian plateau which has for its borders on the north the Hindu Kush and the Elburz, on the east the Indus, on the south the Persian Gulf, and on the west Kurdistan and the Tigris. The term is now the official designation of the kingdom of Persia. In early times the inhabitants of the Iranian plateau, together with the peoples of the adjoining parts of India, bore the common appellation of Aryans.

'Iraq, an Arab kingdom including Mesopotamia (q.v.), stretches from the head of the Persian Gulf to beyond Mosul, where it touches Turkey. The country slopes abruptly from the mountainous region on the Persian border to the valley of the two rivers, beyond which is the desert. The Euphrates and the Tigris and their tributaries fill the central portion, and the main trade routes of the country follow their course. Baghdad the capital, Mosul in the north, and Basra near the Persian Gulf, are the chief towns, but Hilla, Karbala, Kirkuk, and Muhammareh are also centres of importance. Of the ancient metropolises, such as Ur, Kish, Babylon, Nineveh, Ctesiphon, and Asshur, only ruins now remain. It is divided into three vilayets, Baghdad, Basra, and Mosul, which together have an area of 143,200 sq. m., and a population of about 3,000,000. Shias have a majority over Sunnis. The soil is almost unbelievably fertile, but the climate is unhealthy, owing, at least in part, to large areas of swamp. Lower 'Iraq is the old 'Iraq-Arabi, roughly the land of ancient Babylonia, which contains the cities of Babylon, Ctesiphon, and Seleucia. 'Iraq was conquered from the Turks during the Great War (q.v.) by Great Britain, and was afterwards recognised as an independent Arab state under the mandate of that country. In 1921, after a plebiscite, the British High Commissioner proclaimed Faisal, the third son of the first king of the Hejaz, as king. In 1923 it was agreed that the British mandate should lapse on the entrance of 'Iraq to the League of Nations. A new treaty was signed in 1926.

The product of greatest value and importance, and the one likeliest to cause friction for its possession, is oil. There are wells of considerable producing power at Qaiyara near Mosul and at Mandali near the Persian frontier. Wheat, barley, dates, cotton, rice, and ground-nuts are grown. The ancient irrigation system has long been in decay; but owing to the Hindiya Barrage (q.v.) a large area of land has become prosperous, which had been barren and unpopulated. Canals join the Tigris to the Euphrates. 'Iraq is fortunate in its communications, and there is now a railway connecting Mosul and Basra through Baghdad. Not much more is required to connect the Persian Gulf with the Bosphorus and the Gulf of Iskanderun. There are also lines running from Baghdad to Ramadi, to Kut el-Amara, and to the Persian frontier at Kuretu, with an extension to Kirkuk. There are several caravan routes across the desert places, and roads which, although poor, help to open up the country. The northern boundary question was in 1924 passed to the League of Nations, Turkey claiming much of Mosul. The history of 'Iraq is the history of the countries from whose ruins the new state has been built, and will be seen under such headings as BABYLONIA, ASSYRIA, KHALIF, TURKEY.

'Iraq-Ajemi (Persian 'Iraq), a central region of Persia, nearly coincident with ancient Media. A great portion of the surface consists of elevated tablelands, but there are also numerous fertile valleys only partly cultivated. The eastern parts are occupied by the extensive salt desert of Dashti-Kavir. The region contains the principal towns of the kingdom, including Teheran, the capital, and Isfahan.

'Iraq-Arabi. See 'IRAQ.

Irawadi, or **IRRAWADDY**, the principal river of Burma, whose headstreams were long confused with the upper waters of the Sampo or Brahmaputra, and of the Salwin, is formed by the union, in 25° 50' N. lat., a considerable distance above Bhamo, of the Mali-kha and the N'mai-kha. Those two arms are believed to have their sources

Ipswich, a county borough of Suffolk, 69 miles N.E. of London by rail, is situated on the side of a hill on the left bank of the river Gipping, which, here taking the name of the Orwell, becomes tidal, and after a south-easterly course of 12 miles more falls into the German Ocean at Harwich. In the older portions of the town, principally grouped near the river, the streets are narrow and irregularly built, and still retain many picturesque old buildings, decorated with carved work, such as Sparrowe's House (1567), the Neptune Inn (1639), Archdeacon's Place (1471), and Wolsey's Gateway (1528). There are several caravan routes across the desert places, and roads which, although poor, help to open up the country. The northern boundary question was in 1924 passed to the League of Nations, Turkey claiming much of Mosul. The history of 'Iraq is the history of the countries from whose ruins the new state has been built, and will be seen under such headings as BABYLONIA, ASSYRIA, KHALIF, TURKEY.

'Iraq-Ajemi (Persian 'Iraq), a central region of Persia, nearly coincident with ancient Media. A great portion of the surface consists of elevated tablelands, but there are also numerous fertile valleys only partly cultivated. The eastern parts are occupied by the extensive salt desert of Dasht-i-Kavir. The region contains the principal towns of the kingdom, including Teheran, the capital, and Isfahan.

'Iraq-Arabi. See 'IRAQ.

Irawadi, or **IRRAWADDY**, the principal river of Burma, whose headstreams were long confused with the upper waters of the Sango or Brahmaputra and of the Salwin, is formed by the union, in 25° 50' N. lat., a considerable distance above Bhamo, of the Mali-kha and the N'mai-kha. Those two arms are believed to have their sources

in the Namkui or Khanung range, that walls in the Zayul basin on the south; they certainly come from that direction. The Mali-kha seems to rise near the mountain Daphabum, on the borders of Assam, Upper Burma, and Tibet; the N'mai-kha farther to the east or north-east, also near the Tibetan border. From Bhamo the Irawadi has a sinuous channel, its predominant direction being south. Over this entire stretch (about 700 miles) it is navigable for small boats, in spite of numerous islands and sandbanks that litter its channel, and in spite of two rock-bound defiles through which it passes between Bhamo and Mandalay. A third defile occurs nearly 100 miles above Bhamo. Its waters are muddy, and its current generally rapid. Before reaching the sea, in nearly a dozen mouths, in the west of the Bay of Martaban, the river spreads out in a wide delta, 18,000 sq. m. in extent. Of its mouths two only are used by sea-going vessels, the Bassein on the west and the Rangoon on the east. The valley and plain of the Irawadi are very fertile, and grow vast quantities of rice. The river is the chief artery of the country: on its banks stand the principal towns, Bassein, Rangoon, Prome, Ava, Mandalay, Bhamo; its banks were the home of Burmese civilisation; its waters have served as the main means of communication not only to the interior of Burma, but to the south-western provinces of China and of Tibet. The river drains an area of at least 158,000 sq. m. Its largest affluent, coming from the right hand, is the Chindwin. This and the two left-hand tributaries, the Shweli and Myit-nge, are alone navigable. The plain for 150 miles from the sea, being liable to annual inundations, has been protected by embankments built along each side of the river since 1863.

Irbit, a town of the Russian government of Perm, 1170 miles nearly due E. of St Petersburg, celebrated for its fair, held in February and March, next to that of Nijni-Novgorod the most important in Russia; pop. 21,000.

Ireland, an island lying to the west of Great Britain, between 51° 28' and 55° 21' N. lat. and 5° 20' and 10° 26' W. long. It is washed on the N., W., and S. by the Atlantic, and on the E. by the North Channel (13 miles wide), the Irish Sea (138 miles), and St George's Channel (47 to 69 miles), which separate it from the larger island of Great Britain. It is an irregular rhomboid in shape, its greatest length, from Fair Head in Antrim to Crow Head in Kerry, being 302 miles; its greatest meridional length is 225 miles, and the average breadth 110 miles. The island was known to the Greek geographers as *Ierne* (Strabo), and to the Latins as *Hibernia* and *Juverna*. From the latest of the prehistoric occupants of 'The Green Island,' the invading Milesians or Scots, came the Latinised *Scotia*, one of the names by which the 'Isle of Saints' was known from the 6th till the 13th century.

Population.—In 1801 the population of Ireland was 5,395,456 (a density of 166 per sq. m.); this greatly increased, until in 1841 it reached 8,175,124 (251 per sq. m.); thereafter, owing to emigration (in 1883, 108,724 to the United States), a steady decrease set in, so that in 1911 the population was only 4,390,219 (135 per sq. m.). Between the years 1861 and 1920 a total of 4,338,199 persons emigrated from Ireland. In 1911, 780,867 belonged to the agricultural class, 613,397 to the industrial, 170,749 to the domestic, 141,134 to the professional, and 111,143 to the commercial. In 1911 there were eight towns of over 20,000 inhabitants, of which Dublin had 397,957, and Belfast 386,947. At the census of 1920 there were in the United States 1,352,155 persons of Irish birth, and in Canada

823,150. Indeed, the Irish are to be found in all parts of the British Empire.

* The figures for 1881 and 1911 include soldiers and sailors serving in Ireland; the figures for 1841 exclude them.

Coasts and Physical Aspects.—The eastern coast is comparatively uniform and even; but the coasts on the north, west, and south are in many places rocky and high, and indented with numerous deep bays, especially at the south-west corner of the island. Most of these bays afford excellent harbours, some even for the largest of modern warships. On the west may be named the Bays of Donegal, Sligo, Clew, Galway, the estuary of the

Shannon, and Dingle, Kenmare, and Bantry bays; on the south the spacious harbours of Cork and Waterford; on the north Loughs Foyle and Swilly, which both penetrate a long distance inland. On the east side, opposite England, are Wexford Haven, the Bays of Dublin, Drogheda, and Dundalk, and Carlingford and Belfast loughs. Numerous islands occur, especially on the west, but they are for the most part small in size. Valentia, in the extreme south-west, was the terminus of the first Atlantic cables to North America, and of others since. On the west too are the islands of Aran, Achil, the Inishkeas, &c. Off County Antrim, in the north-east, is Rathlin Island. In Antrim is the Giants' Causeway (q.v.).

The surface is, generally speaking, an undulating plain, relieved, more particularly towards the coasts, by detached groups of low hills. The principal ranges are the Mourne Mountains in Down, which attain their highest elevation in Slieve-Donard (2796 feet); the mountains of Wicklow, which rise in Lugnaquilla to a maximum height of 3039 feet; and Mauglicuddy's Reeks, in Kerry, their highest peak, Carran-Tual (3414 feet), being the loftiest in all Ireland. The central parts of the island are quite flat, and consist very largely of bogs or morasses, which occupy altogether 1,772,450 acres, or nearly one-ninth of the entire area. The largest is the Bog of Allen, which stretches over a large portion of Kildare, Carlow, King's and Queen's counties. These bogs have an average depth of 16 to 25 feet, but occasionally go down to 47 feet; they yield large quantities of peat or turf, and contain numerous remains of skeletons of men and animals, and relics of human habitation and occupancy. Extensive tracts of deep wet bog occur in Longford, Roscommon, and other counties, and give a peculiarly dreary and desolate aspect to the scenery.

Hydrography.—The principal river of Ireland, and the largest in the British Islands, is the Shannon (q.v.). The streams which drain the eastern part of the central plain are the Liffey and Boyne; the south-eastern part, the Suir, Barrow, and Nore; while the waters of the north-eastern part are collected into Lough Neagh, chiefly by the Blackwater, and are thence discharged into the sea by the Lower Bann and Newry Canal. The rivers external to the great central plain are necessarily short. The principal are the Erne, flowing to the north-west; the Foyle and Bann, to the north; the Lagan, to the north-east; the Slaney, to the south-east; and the Bandon, Lee, and Blackwater, to the east, through the county of Cork. None of these rivers are of much importance to navigation beyond their estuaries, though small boats can ascend some distance up the larger streams by the aid of canals, locks, &c. Artificial rivers or canals connect some of the more important trading centres; for instance, Dublin has water-communication with the Shannon by means of the Grand (165 miles) and Royal (76) canals, and Lough Neagh with the same river by the Ulster Canal and river Blackwater.

The lakes of Ireland (called loughs) are both numerous and extensive in proportion to the size of the island. The largest is Lough Neagh in Ulster, covering an area of nearly 100,000 acres. The other loughs of consequence are Erne and Derg, also in Ulster; Conn, Mask, and Corrib, in Connaught; Allen, Ree, and Derg, expansions of the river Shannon; and the lakes of Killarney (q.v.) in Munster. The name lough is also applied to many salt-water inlets (see above).

Geology.—The configuration or relief of Ireland is, as a matter of course, intimately related to the geological structure of the island. The mountains

are built up of relatively hard crystalline schists and disturbed Lower Palæozoic rocks, while the low grounds are nearly co-extensive with less indurated and comparatively undisturbed Upper Palæozoic strata. The interior and larger portion of the island is in fact a great undulating plain, the central area of which, between Dundalk Bay or Dublin Bay in the east and Galway Bay in the west, does not exceed a height of 250 feet above the level of the sea. The strata throughout this central plain belong almost exclusively to the Carboniferous system. Here and there the ground rises to heights ranging between 1000 and 3000 feet so as to form more or less isolated hills and groups of hills and mountains as Slieve Bloom, the Silvermine Mountains, Slieve Bernagh, Galtymore, &c. These are simply islets of older Palæozoic rocks that peer above the general level of the great Carboniferous plain. The chief highlands of the island are met with in the maritime regions. Thus we have in the north the highlands of Donegal and Derry, the plateau-basalts of Antrim, and the Mourne and Carlingford Mountains with Slieve Gallion; in the south the highlands of Kerry and Cork, with Knockmealdown, &c.; in the west those of Mayo, Galway, and Connemara; and in the east the mountains of Wicklow.

Ireland is thus built up chiefly of Palæozoic rocks—strata of Mesozoic and Cainozoic age being very meagrely developed. *Archæan* gneissose and schistose rocks occur chiefly in the north-west and west—the coarse granitic gneiss of Donegal being regarded as belonging to the same series as the gneissose rocks of the north-west Highlands of Scotland. The oldest of the fossiliferous systems, the *Cambrian*, is well represented in the south-east of Ireland, where it attains a thickness of 14,000 feet at least. The strata are upon the whole unfossiliferous, but numerous surface-markings have been detected, chiefly worm-tracks, &c. In many places these rocks have been much metamorphosed. Thus on the Howth coast they are represented by quartz-rocks and schists, while in Wexford they pass into gneiss. Similarly in Galway over considerable tracts the Cambrian seems to be represented by schistose rocks; some of these, however, seem to be of Archæan age. The *Silurian* system is likewise well developed in the island—both lower and upper divisions being present. This system, like the Cambrian, occurs chiefly in the hillier parts of the country. In the Donegal district the rocks are much metamorphosed, and are doubtless the equivalents of the altered Lower Silurian strata of the Scottish Highlands. The same rocks reappear in Mayo and Galway; in the last-named district they are overlaid unconformably by unaltered Upper Silurian sandstones, conglomerates, and shales. Fossils occur here and there in the less altered portions of the Lower Silurian, but are not nearly so common as in the overlying upper division. It is noteworthy that not only are the Upper Silurian strata unaltered, but they contain rolled fragments of the metamorphosed Lower Silurian rocks upon which they rest. It may be added that contemporaneous volcanic rocks are associated with the Upper Silurian strata of Galway. Coming farther south we encounter another thick series of Upper Silurian strata in the Dingle promontory. In the districts of Waterford, Wexford, Wicklow, and Louth Lower Silurian strata are likewise well developed, and are noted for the evidence which they have supplied of contemporaneous volcanic action.

No representatives of the marine *Devonian* are known in Ireland, but the lacustrine or *Old Red Sandstone* type is well developed in the south and south-west. Two divisions are recognised—the upper unconformable to the lower, which latter

reaches a great thickness. The rocks of the latter are chiefly grits and slates, which have yielded certain bivalve shells (Anodonta), probably of fresh-water origin, but no traces of the marine Devonian fauna. The upper division consists chiefly of flagstones and tilestones, and is of no great thickness. The chief fossils are worm-tracks and ferns. This division appears sparsely in the centre and north of Ireland, where the general character of the strata recalls that of the Old Red Sandstone of central Scotland. The series passes up conformably into the Carboniferous system.

The *Carboniferous* system occupies about one-half of the area of Ireland, but the strata belong chiefly to the lower division—viz. the Lower Carboniferous and the Carboniferous limestone, which latter is essentially the formation of the plains. The upper members of the system occur in a few detached patches scattered over the surface of the great central plain, the major portion of which was probably at one time covered with Upper Carboniferous strata. The basement beds of the system in the south of the island consist chiefly of marine grits and slates, which pass down conformably into the Upper Old Red Sandstone. In the centre and north this lower division is represented by conglomerates, grits, sandstones, shales, and earthy limestones, which appear to be the equivalents of the 'Calcareous sandstones' of Scotland. Overlying these basement beds comes the great Carboniferous limestone (2500 to 5000 feet thick), which occupies most of the central plain, extending east and west from sea to sea, and stretching from the base of the Donegal Mountains to the foot of the Killarney Mountains in the south. In Donegal the limestone rises into a tableland which overlooks the shores of Donegal Bay in bold bluffs and headlands, and reaches from 1500 to 2000 feet above the level of the sea. Contemporaneous volcanic rocks accompany the limestone series in the south-west (Limerick and Tipperary). In the south and in the north the limestones are overlaid by marine sedimentary deposits which are believed to be on the same general geological horizon as the 'Yoredale beds' and 'Millstone grit' of England. Succeeding this group comes the 'Coal-measures' series, the lower portion of which is supposed to represent the 'Gannister beds' or lower coal-measures of England, while the upper portion represents the middle coal-measures of the same country. The productive coalfields of Ireland are of small extent. They are confined to limited districts in the north and south, as in Tyrone, Tipperary, Kilkenny, and Carlow—all the coal of the south of Ireland being anthracitic.

The Upper Palæozoic and Cainozoic rocks of Ireland are confined to the north-east of the island, where they appear to owe their preservation in chief measure to the great outflows of basalt which form the high grounds of Antrim. *Permian* strata are very sparingly developed, but both the Lower Permian and the overlying *Magnesian limestone* of England are represented. The lower division is characterised by the presence of coarse breccias like those of Shropshire. The Permian is seen at Armagh and in Tyrone.

The *Triassic* system is likewise sparingly represented, occurring in a narrow band round the basalts of Antrim and Derry. The rocks are chiefly red and mottled sandstones and marls, with gypsum and extensive beds of rock-salt. These strata are overlaid by certain dark shales, which have yielded 'Rhætic' fossils.

The great *Jurassic* system of England is for the most part unrepresented in Ireland, but a few shales which come out from underneath the chalk escarpment of Antrim have been identified by their fossils as pertaining to the Lower Lias.

Cretaceous strata (Upper Greensand and Chalk) crop out from underneath the basalts of Antrim, to which doubtless they owe their preservation. There is reason to believe that the Cretaceous beds formerly covered a much more extensive area in the north of Ireland. They may at one time have extended continuously from the high grounds of Donegal in the north-west to the Mourne Mountains in the south-east.

The Tertiary or Cainozoic rocks consist chiefly of volcanic accumulations (trachytes and basalts); their age is determined by the occurrence of intercalated 'leaf-beds,' the plants in which show that the series belongs to the *Oligocene* system. Many of the basalts are beautifully columnar (Giants' Causeway). The volcanic rocks appear to have been the products of great fissure-eruptions for the most part, but the 'necks' or plugged-up throats of isolated volcanic foci have been detected. The whole area in this north-east part of Ireland is traversed in all directions by basalt dykes.

Along the southern shores of Lough Neagh fresh-water clays occur, the fossils in which are of *Pliocene* age, so that this Irish lake is probably the oldest sheet of fresh water in the British Islands.

Ireland, like the sister island, abounds with evidence of the *Glacial* period. The whole country has been buried under a great *mer de glace*, which was continuous with that of Scotland and England. The bottom-moraines (boulder-clay) of this ice-sheet are encountered everywhere. Irish geologists recognise two boulder-clays separated by intervening stratified deposits of marine origin (see *PLEISTOCENE SYSTEM*). Local moraines due to the 'retreat' of the great *mer de glace* are common in mountain-valleys. *Recent deposits* are seen in raised beaches, alluvial terraces, and bogs.

Animals.—Twenty-one species found in Great Britain are unrepresented in Ireland. Frogs are common enough, also toads; but the adder, mole, shrew, water-shrew, water-vole, the two land-moles, wild-cat, polecat, weasel, and roe-deer are unknown; only the blue-hare is indigenous.

Climate.—The climate resembles that of Britain, but is modified by Ireland's different surface, its greater distance from the Continent, and the more direct influence of the Gulf Stream. In Ireland there are 3° F. of difference between the extreme north and south. In January the mean temperature at inland situations in the north is 39.5°, whilst in the extreme south-west it is 45.2°; whilst in July the extreme mean temperatures are 58.2° at Malin Head in the north and 60.5° at Parsonstown in the interior. Thus in winter the difference of temperature of different districts is 5.7°, but in summer it only amounts to 2.3°. Ireland enjoys, therefore, a climate more equable in all seasons than those parts of Great Britain which are within the same latitudes. About half the whole island has a rainfall of from 30 to 40 inches, and the other half from 40 to 60 inches, the former region being in the east and the latter in the west. Thus the rainfall is very much more equally distributed over Ireland than over Great Britain. The rainfall in winter is greatly in excess of that in the other seasons, particularly in the west, owing to the low temperature of the surface of the ground, which chills the warm and moist south-west winds that prevail at this time of the year. In Ireland the hills in the west do not oppose a continuous barrier to the onward progress of the south-west winds, but are more broken up and distributed in isolated groups than in Great Britain. Consequently the sky is more clouded, rain falls more frequently and more generally over the whole of Ireland than Great Britain, and the climate is thus rendered more genial and fostering to vegetation; hence the appropriate-

ness of the name 'Emerald Isle.' Again, the east winds of spring are less severely felt, because they have acquired warmth and moisture in their progress over Great Britain and the Irish Sea. Queenstown, in the south-west, enjoys an average spring temperature of 49°, about 2·5° higher than at Dover.

Agriculture.—Down to about the middle of the 18th century Ireland was almost exclusively, and still is to a large extent, a pastoral country. The chief reasons of the backwardness of agriculture have been prohibitive and unsuitable legislation, the extreme smallness of the greater number of holdings, the lack of capital, and the unsatisfactory relations of landlord and tenant. As a rule large farms were let for extremely long periods of tenancy, and the tenants sublet their farms in smaller portions, sometimes two or three times over; consequently the landlords seldom erected buildings, repaired farmsteads, or made permanent improvements. In 1879-80 the distress amongst the poorer sections of the community had reached such a pitch that the government took action, and in 1881 the Land Law (Ireland) Act was passed. Its principal measures were designed to protect the tenant from paying more than a 'fair rent,' and to provide for loans being made to tenants to enable them to purchase their holdings on fair and equitable terms. The Irish Land Acts of 1903 and 1909, supplementing acts passed from 1885 to 1896, gave greatly increased facilities to tenants for purchasing their holdings. Apart, however, from any political cause, there is the underlying natural reason, namely, that owing to the excess of rain and the mildness of the winter grass which in Great Britain is dried up is in Ireland suitable for pasture all the year round.

Irish Free State.—In 1922, 3,802,121 acres were under crops, the chief of which were oats (813,970), potatoes (400,982), turnips (199,234), barley (167,747), wheat (which will only ripen in certain districts), mangels, cabbage, rye, and flax; while hay covered an area of 2,062,694 acres, from which 3,843,361 tons were taken. The agricultural land was under holdings, which were in the hands of 450,000 separate occupiers. With such excellent pasture-ground as is available it is easily understood how the raising of live-stock is one of the principal, if not the principal, industry. In 1922 the cattle numbered 4,326,294 and the sheep 3,067,473, while there were large numbers of pigs and goats. Horse-raising, especially in the south, whose hunters and hackneys have a world-wide reputation, is profitably carried on, and dairy-farming is increasing. Many of the small farmers have benefited largely from the development since 1890 of co-operative agricultural societies.

Northern Ireland.—In 1922, 1,155,786 acres were under crops. Flax, though not under the largest acreage, is of extreme importance, as upon it the linen industry of Belfast largely depends. Oats covering 399,722 acres, potatoes 168,567, and turnips 48,677, were important crops. Over 780,000 tons of hay were also produced, and 10,000 acres were under fruit. There were 129,000 agricultural holdings in the hands of 13,700 separate holders. The live-stock numbered: cattle, 830,331; sheep, 499,048; pigs, 117,277; and horses, 115,360.

Fisheries.—The seas around the coasts of Ireland teem with fish, and owing to its configuration no part of the country is more than 50 miles from the sea; but from various causes, chiefly perhaps the distance of the most productive fishing-grounds from the centres of population, and the fact that the most modern commercial principles have not been observed, the fisheries are not in a flourishing condition. The deep-sea fish of greatest commercial value are mackerel, herrings, hake, soles,

cod, lobsters, and oysters. Herrings, mackerel, and cod are exported to England. The inland fisheries are of value, as some of the finest of salmon grounds are to be found there.

Manufactures.—*Irish Free State.*—Brewing (the products of which form very important exports) and distilling are carried on. Woollen goods are also manufactured (Kilkenny), and knitting, embroidery, and lace-making are extensively practised, although the flourishing conditions of the 17th century, when the woollen products of Ireland were noted, have left the trade. This is owing largely to the unsettled condition of the country and the general and growing dependence of the population on agriculture. Ham and bacon curing are common to the whole country, but are inclined to have their centre in Cork. Tobacco manufacturing, flour-milling, biscuit-making, and tanning are also found, and the making of poplin is confined as before to Dublin. Iron, coal, and zinc are mined.

Northern Ireland.—Conditions have not impressed themselves so forcibly as in the south, and very important linen and shipbuilding industries have been built up. The staple is the manufacture of linen, introduced by Strafford in 1633, and much encouraged by the Duke of Ormonde (1661-64). The mills are situated principally in Belfast, round which is grown the flax from which the trade derives its life-blood. Shipbuilding is of especial importance, as in the Belfast shipbuilding yards war and commercial ships of the very greatest tonnage are built. These yards employ large numbers of men.

Commerce and Shipping.—The exportation of agricultural produce constitutes the bulk of the commerce, and by far the greater part of this trade (in cattle, sheep, pigs, salted meat, grain, flour, butter, eggs, and linen) is carried on with Great Britain, chiefly between Dublin and Belfast on the one side and Liverpool, Glasgow, and Bristol on the other.

Government, Police, &c.—The government of Ireland was from 1801 to 1922 amalgamated with that of Great Britain. It was represented in the Imperial parliament by 28 peers elected for life in the House of Lords, and in the House of Commons by a number of members, changed in 1918 from 102 to 105. The executive was vested in a lord-lieutenant, who was assisted by a chief-secretary and a privy-council (appointed by the crown). However, since 1922, the government has entirely changed, and Ireland has been divided into two separate and self-ruling regions as a result of the Home Rule agitation (see below under HISTORY).

Irish Free State.—The Irish Free State is a co-equal Imperial entity with the other self-governing Dominions in the British Commonwealth of Nations, with the power of government derived from the people. The legislature (Oireachtas) comprises the king, a senate (Seanad Éireann), and a chamber of deputies (Dáil Éireann). Members of the senate are chosen from those who have given distinguished service to the state, and members of the Lower House by the direct vote of all citizens of over twenty-one years. The executive is vested in the king and through a representative known as the governor-general (as in Canada). There is also an executive council of 12 members, and the judiciary was established with a right of appeal to the king-in-council.

The Royal Irish Constabulary have been disbanded (see POLICE); the office of resident magistrate abolished. A small army of 20,000 is allowed, but is not to be employed in foreign wars without the consent of the legislature.

Northern Ireland.—Responsible government was given by the act of 1921. The executive is in the

hands of the king acting through the governor and the government of the state. The senate consists of 28 members, including the Lord Mayor of Belfast and the Mayor of Derry as *ex officio* members. The Lower House has 52 elected members, and Northern Ireland has also a representation of 13 members in the parliament of the United Kingdom. Matters relating to the crown, the navy, army, air force, foreign treaties, treason, and such like are not in the hands of the legislature, but except for such matters it has full powers.

Religion.—In 1911, 73·9 per cent. of the population were Roman Catholics, 13·1 per cent. Episcopalians, 10·0 Presbyterians, 1·4 Methodists. The Roman Catholic Church has 4 archbishops (Armagh, Dublin, Cashel, and Tuam) and 24 bishops. The Episcopal Church has 2 archbishops (Dublin and Armagh) and 11 bishops.

	Roman Catholics.	Others.
Leinster.....	990,045	171,999
Munster.....	973,805	61,690
Ulster.....	690,816	890,880
Connaught.....	588,004	22,980

Of the Roman Catholics in Ulster, 260,655 were in the counties of Cavan, Donegal, and Monaghan.

Education.—In 1911, in all Ireland 88 per cent. of the population above nine years of age could read and write, 3 per cent. could read only, and 9 per cent. could do neither.

Irish Free State.—In the Free State the primary schools are under the control of the government, which pays the salaries of the teachers and contributes to the cost of building and upkeep. Primary education is compulsory in many parts. Secondary education is under private control, chiefly that of religious houses. The most important university in Ireland is that of Dublin (q.v.) or Trinity College, founded in 1591. The Royal University of Ireland, an examining body founded in 1880, superseded the Queen's University, and was superseded itself in 1909 by the National University with three university colleges—University College, Dublin, a new foundation, and the old Queen's (now University) Colleges at Cork and Galway. The Royal College of Science in Dublin was founded in 1867 to give instruction in branches of science applicable to the industrial arts, especially in mining, agriculture, manufactures, and engineering. The Roman Catholic university, founded in 1854, has its headquarters in Dublin, but has constituent colleges at Maynooth, Blackrock, Carlow, and Clonliffe. St Patrick's College, Maynooth (q.v.), opened in 1795, is the principal institution for the education and training of Roman Catholic priests.

Northern Ireland.—All the old bodies, such as the Commissioners of National Education, Board of Intermediate Education, &c., are now merged into the Ministry of Education, which is co-ordinating the whole system of education. Elementary education is catered for by 2000 national schools, where attendance is compulsory. There are secondary schools of a high standard, many in private hands. The Queen's University of Belfast, founded in 1849 as a college of the Queen's University of Ireland, has since 1909 been an independent home of learning. Two Presbyterian colleges at Belfast and Londonderry were in 1881 empowered to grant theological degrees.

Communication.—The first railway opened in Ireland was the short line, 6 miles long, between Dublin and Kingston in 1834. There were in 1923 some 3442 miles in operation. The railways are constructed on a broader gauge than those of Great Britain—viz. 5 feet 3 inches, as compared with 4 feet 8½ inches; but several built since 1878 (see RAILWAYS) are only of 3 feet gauge. The first considerable electric tramway in the British Isles was that from Portrush to the Giants'

Causeway (1883). The canals, rivers, and lakes have been already mentioned.

BIBLIOGRAPHY.—The earliest account of Ireland is contained in Giraldus Cambrensis, *Topographia Hibernie* and *Expugnatio Hibernie*. Subsequent accounts will be found in Holinshed, *Chronicles* (1577); R. Payne, *Brief Description of Ireland* (1590); E. Hogan, *Descr. of Ireland in 1598* (1878); Sir J. Davies, *Discoverie of the State of Ireland* (1613); Edmund Spenser, *View of the State of Ireland* (written 1596; printed 1633); Sir Wm. Petty, *Political Anatomy of Ireland* (1691), and *Geog. Descr. of the Kingdom of Ireland* (1700); *Constitution of Ireland and Poynings' Laws Explained* (1770); Arthur Young, *Tour in Ireland* (1780); César Moreau, *Past and Present State of Ireland* (1827); Thackeray, *Irish Sketch Book* (1843); Sir Robert Kane, *Industrial Resources of Ireland* (1844); Dufferin, *Irish Emigration and Tenure of Land in Ireland* (1867); M. Murphy, *Ireland, Industr., Polit., and Social* (1870); O'Curry, *Ancient Manners and Customs of Ireland* (1873); Hall, *Physical Geology and Geog. of Ireland* (1878); Kinahan, *Manual of Geol. of Ireland* (1878); O'Brien, *Hist. of Irish Land Question* (1880); Richey, *Irish Land Laws* (1880); Robert Dennis, *Industrial Ireland* (1887); J. Roisdan, *Modern Irish Trade and Industry* (1922); G. A. J. Cole, *Minerals and Mines in Ireland* (1923); Cole and Hallissy, *Geology of Ireland* (1925).

HISTORY.—The history of Ireland, like that of almost all ancient countries, 'tracks its parent lake' back into the enchanted realms of legend and romance and fable. It has been said, not untruly, of Ireland that she 'can boast of ancient legends rivalling in beauty and dignity the tales of Attica and Argolis; she has an early history whose web of blended myth and reality is as richly coloured as the record of the rulers of Alba Longa and the story of the Seven Kings.' We cannot get at any hint of the actual truth about Conn of the Hundred Fights and Fin Mac Coul and Oisín. But the impression which does seem to be conveyed clearly enough from all these romances and fables and ballads is that there was in Ireland a very ancient civilisation, and that the island was occupied in dim far-off ages by successive invaders who came from the south. From recent discoveries it appears that Bronze Age implements were in existence in the west of Ireland as early as the 17th century B.C. In the Iron Age Britons from the south-west crossed to Ireland and the Picts from the north. Phœnicians and Greeks may have been among Ireland's visitors, and, according to legend, a Milesian race formed the kingdom of Tara in 500 B.C. What may be called the authentic history of Ireland begins with the life and career of St Patrick. Patrick, born in Scotland, was carried as a slave to Ireland, escaped to Rome, and, rising to the rank of bishop, landed at Wicklow in 432, with the object of converting the island to Christianity. In this he was entirely successful. At this time Ireland was divided into septs or clans, who all owed allegiance to the chief king. All the chieftainships were elective, and during the lifetime of each chief his successor was chosen from the same family, and was called the Tanist. All the land was held by the septs for the benefit of the people, and there was no feudal condition, and no system of primogeniture. Near to the close of the 8th century the Danish sea-rovers invaded Ireland, overran great part of it, and made settlements on the eastern coasts. The Irish chiefs were divided among themselves and could not keep out the enemy, and the Danish occupation lasted for much more than a century. At last a strong and capable Irish chieftain, Brian Boromhe, brother of the king of Munster, defeated the Danes at the

battle of Tara in 980, and, although he did not drive them out of the country, he reduced them to the condition of subdued and submissive residents. Brian now made himself king of Ireland, and for twelve years reigned a successful ruler over a peaceful and prospering country. As he grew old the Danes plucked up spirit again, and got a fleet and an army from their kinsmen across the sea to invade Ireland. ~ Brian, old as he was, proved himself equal to the occasion. He completely defeated the Danes at Clontarf, 23d April 1014. After the withdrawal of the Danes there was much intestine strife, which paved the way for a far more momentous event in the history of Ireland—the Norman invasion (1167-72). This took place in the reign of Henry II. (q.v.), and is another story of Helen of Troy. The king of Leinster carried off the wife of the chieftain of Breffni. The injured husband made war upon his wronger; the king of Leinster was getting the worst of it, and fled to England, and induced Henry II. to lend him countenance and even help. Henry took the opportunity offered him by the fugitive king of Leinster, and, after despatching an army to Ireland, afterwards came over himself to finish the conquest, and eventually conquered a portion known as the 'Pale,' in which he settled his Norman barons, giving them large grants of land, the septal property of the island. These he left to hold the land as best they might, and in a way so began the great land struggle which has lasted almost to the present day.

The history of Ireland for a long time after the settlement of the Normans becomes nothing but a monotonous recital of the struggles between the Norman barons and the Irish chieftains, and the struggles between one Irish chieftain and another. The Norman or English barons lived within the cincture of their own domains and administered affairs on the feudal system. Outside were the Irish, who still strove hard to keep up their own laws, their own customs, and their own civilisation. They had no rights which a Norman was bound to recognise. As time went on, however, a curious change was taking place. The English began to be drawn very much towards Irish ways and Irish people. They took to marrying Irish women and speaking the Irish language. Severe enactments were passed by the English to prevent this, but unsuccessfully, and Englishmen still married Irishwomen, and in many ways adopted their language and customs. The great Norman family of the Geraldines was described as more Irish than the Irish themselves. By the time that Henry VII. had come to the throne the greater part of the island was in the hands of Anglo-Irish chieftains. There was a parliament on the Norman idea sitting in Ireland and illustrating at least the principle of a representative system. Henry VII., however, when Perkin Warbeck and Lambert Simnel obtained help from Ireland, in retaliation sent over Sir Edward Poyning as lord-deputy, with a strong army at his back and with ample authority to make a great change. Poyning summoned a parliament at Drogheda, and compelled it to pass the famous measure known as Poyning's Act (1494). This act declared that all English laws should have force in Ireland, and that all legislation in the Irish parliament should be confined to measures which had been first approved of by the king and the privy-council in England. Poyning's Act is an epoch in the history of Ireland.

Henry VII. died. The Geraldines defied the power of Henry VIII. 'Silken Thomas' (Lord Thomas Fitzgerald) led a desperate revolt against the king, but after a hard struggle he was defeated. Henry confiscated the church lands in Ireland exactly as he had done in England. A parliament

was summoned in Dublin, at which, for the first time, some of the Irish chieftains were seen sitting side by side with Englishmen. These were certain of the Irish princes who had agreed to hold their lands as the gift of the crown, to attend the king's parliament and seek justice in the king's courts, to send their sons to be educated in England, and to renounce the authority of the pope. This parliament conferred on Henry and his successors the title of King of Ireland instead of Lord Paramount (*Dominus Hibernie*), the former designation of the sovereign. A weary chapter of struggle followed the death of Henry VIII., who had done his best to compel the Irish chieftains and people to give up the faith of Rome and adopt what was now the faith of the majority in England. This was but a new source of bitterness and strife. The great family of O'Neill raised its head higher than ever, and the chief whom, in defiance of English law, it elected to that place, Shane O'Neill, was actually able to make terms with Elizabeth. The Geraldine League was formed. Walter Devereux, the first Earl of Essex, was sent over in 1573 to put down the O'Neills; but although he slaughtered whole masses of them he could not extirpate them. A chronic state of civil war prevailed. After each new rising had been put down there was a new confiscation of territory, a new planting of English and Scottish settlers, and a new attempt to expel or extirpate the native Irish. 'Red Hugh O'Neill' was the most distinguished rebel who had yet appeared in Ireland. He was the grandson of an O'Neill who had consented to accept from Henry VIII. the title of Earl of Tyrone. Hugh O'Neill had been brought up at the court of Elizabeth, and was confirmed in his title of Earl of Tyrone. But when he went back to his own country he resumed his ancestral title of 'The O'Neill,' and put on all the ways of an independent Irish prince. He did not at first go into open rebellion; but 'rebellion lay in his way, and he found it.' He put himself at the head of a great rising of the chiefs, and he won a complete victory in Ulster over Sir Henry Bagenal, the lord-marshal. Bagenal himself was killed. For a while fortune seemed to smile on Hugh O'Neill. Robert, the second and most famous Essex, was despatched in 1599 to defeat him, with the largest army ever sent into Ireland up to that time; but Essex could do nothing. He was outgeneralled and outwitted by the Irish chief, and went back to England and his death. Lord Mountjoy, a stronger soldier, was sent to Ireland in his place, and he at last succeeded in defeating Tyrone and putting down the rebellion. O'Neill had to come to terms, and to renounce all his claims as independent Irish prince. Elizabeth died, and James I. accepted the surrender.

But James had set his heart on getting rid of all the Irish laws and usages of the country, and if possible putting down the Roman Catholic religion. Tyrone and another Irish chief, Tyrconnel, fled from the country, and 'The flight of the earls,' as it is called, left the island completely in the hands of King James. There were again vast confiscations and new settlements. When King Charles succeeded to the throne and came into trouble with his people some of the Irish chiefs thought their opportunity had come. The native Irish in Ulster rose under Sir Phelim O'Neill, not so much against English rule as against the Scottish and English settlers who had been planted there. In that rising, following on the eight years' administration of Strafford (q.v.), occurred what is called 'the massacre of 1641.' So far as one can form any judgment it does not seem as if there was any deliberate and purposed massacre of the Protestants, although it is impossible to doubt that there was a very barbarous slaughtering of Protestants in

one place. The struggles of that time indeed show over and over again hideous incidents which can hardly be described as anything but massacres. The rising soon became something very like a national rebellion. Colonel Owen O'Neill, nephew of the gallant Tyrone—Owen Roe O'Neill, as he is always called in Irish song and history—came over to lead the struggle. He had won a high place in the Spanish army. At first his arms in Ireland were all successful. A parliament was held in Kilkenny—a national convention—in October 1642, to proclaim and establish the independence of Ireland. The papal nuncio Rinuccini came from Rome to give his counsel and support to the movement. Charles himself favoured the Irish, and made many pledges to them in the hope of getting their help; but his execution left Cromwell free to take Ireland in hand. The only man in Ireland capable of meeting Cromwell on a battlefield with any chance of success was unquestionably Owen Roe O'Neill; he had already won one victory over the English forces, but before he had time to throw himself across Cromwell's path Owen died. With O'Neill's death was gone the first and the last and the only chance of any success for the Irish movement. Cromwell's march was from victory to victory. He stamped out the rebellion with merciless severity, and then, like all his victorious predecessors, he went in for a re-settlement of the island. He seems to have contemplated such a plantation of the whole country with English and Scottish settlers as would render any further rising of the Irish impossible, and indeed would before very long lead to the positive extirpation of the Catholic Celts. All Ireland, except Connaught alone, was portioned out among the settlers. Connaught was set apart as a sort of reservation into which the unfortunate Irish were literally driven, and where they were cooped up within certain prescribed limitations. Irish women and girls were shipped off in thousands for virtual slavery or worse in our West Indian possessions.

The Restoration brought the Irish little good, for Charles II. was more anxious to conciliate the Cromwellian settlers than to restore the Irish owners. James II. came to the throne, and the Irish Catholics got better treatment, and in consequence showed a very fervour of loyalty to him. They championed him with all their might when he quarrelled with his people and fled from his throne. The Irish were in all these struggles invariably the losers. They supported Charles I., and brought Cromwell on them; they supported James II., and brought William III. on them. William defeated James at the Battle of the Boyne (1690) and on other fields. Limerick held out to the last, until a treaty was made which promised religious freedom to the Catholics and to King James's followers the right to their estates. The treaty was broken almost immediately after it had been made. William III. might have upheld it if left to himself; but the opinion of his English supporters was so fierce against the Catholics that new penal laws were imposed on Ireland with the avowed purpose of extinguishing Catholicism in the island. These laws have in fact ever since been known as 'the penal laws'—*penal par excellence*.

The two great struggles in Ireland were the religious struggle and the land struggle. The first was part of the great controversy going on all over Europe for the Church of Rome and against it. The main effort of English statesmanship was to extinguish Catholicism in Ireland. The land struggle began with the determination to impose on Ireland a system of land tenure foreign to her habits and traditions, and later on to take the land

from the Irish people and give it to the imported settlers. Under William III. the religious struggle became aggravated; the land struggle was not mitigated; and laws were even passed to crush the rivalry of Ireland in various branches of manufacture and of trade. The island sank into wretched poverty, and when the two successive outbreaks of the Stuarts took place, in 1715 and 1745, Ireland, although undoubtedly in deep sympathy with the cause, was too weak to lift a hand in its support. The rights of the Irish parliament were still further curtailed under Anne and under George I. In the reign of George the appellate jurisdiction of the Irish House of Lords over Irish cases was taken away by an act of the English parliament. The Irish parliament was a very poor specimen of a representative institution. Since William III.'s time it was barred against Catholics. To the vast majority of the Irish people its existence might have been a matter of absolute indifference. Yet the sympathies of the country went with the Irish parliament simply because it was called an Irish parliament, and represented even in name the authority of the Irish people. Gradually there began to grow up in Ireland a popular party led by Protestants, who agitated for the restoration of its independent legislative power to the Irish parliament, and for the reform of that parliament in such a manner as to make it really representative. Grattan and Flood were most prominent in this movement. The war with the American colonies gave an opportunity to the popular party to drive home their demands. A great volunteer force, entirely in sympathy with Grattan, had been organised, and when the war was over they sustained him in his demands. English statesmen very wisely gave way, and in 1782 the Irish parliament was declared to be an independent legislature—'the King, Lords, and Commons of Ireland to make laws for the people of Ireland.' An immense impulse was given to popular agitation by this victory. The new parliament was exclusively Protestant, and was elected by an exclusively Protestant vote. Yet its leaders at once went to work to obtain the emancipation of their Catholic fellow-subjects. Grattan succeeded in obtaining an act to admit Catholics to practice at the bar. He then carried an act to enable Catholics to vote for members of parliament. He went further still; he strove for a measure to enable Catholics to sit in the Irish parliament. In this object he was assisted and encouraged by Lord Fitzwilliam, the viceroy of Ireland. This was too much for George III. The king took fright at the advance made towards full emancipation of the Catholics, and at the very time when the Irish people thought they were near to a peaceful consummation of their hopes the viceroy was suddenly recalled, and all immediate hope of Catholic emancipation blighted.

There had been a society formed during the agitation called the Society of United Irishmen. It was formed as a merely peaceful organisation to assist Grattan in the carrying of his reforms. It was got up and officered almost exclusively by Protestants, many of them young men of rank and influence, like Lord Edward Fitzgerald. In the anger caused by the recall of Lord Fitzwilliam, and in the despair of any peaceful movement, the United Irishmen became a rebel organisation. The war with France was going on. Napoleon was the rising sun of the French people. Wolfe Tone, a daring young Protestant, went over to France and pleaded the cause of Ireland there. Napoleon took it up merely because he thought an Irish rebellion might be fostered into a diversion in his favour. A French fleet was sent, but was dispersed by a storm, like another Armada. A landing was made in one place, but only by a very small force, who were

soon defeated and captured. The rebellion broke out in the south, and there was some fierce fighting, but it was crushed. It had indeed, owing to the French failures, been only a series of disconnected local risings, and had been crushed with remorseless severity. When the rebellion was put down Pitt thought the condition of things could only be bettered by adopting, with regard to Ireland, the same policy that had been adopted with regard to Scotland, and uniting the two islands under one common parliament. Grattan and his leading colleagues, among whom was Sir John Parnell, fought to the last against the policy of union, but they were overborne. The Act of Union came into force on the 1st January 1801. There had been a promise held out to the Irish Catholics that the union should be a preliminary to their prompt emancipation, but King George would not hear of any such concession, and his ministers did not venture to press it on him. The Act of Union was followed almost immediately by the abortive and hopeless rebellion of Robert Emmet. Then a long dark night of conspiracy, agrarian and political, came on. A great movement was made for Catholic emancipation. The movement was led by Daniel O'Connell, and became successful after O'Connell had defied the law, presented himself as a candidate at the Clare election in 1828, and been returned by a great popular majority. It had become a mere alternative between concession and rebellion; concession prevailed, and the Catholics were enabled to sit in parliament. The tithe struggle was for a long time a source of the bitterest trouble and the most frequent bloodshed, but a settlement was at last effected by means of which the tithe-collector and the peasant were no longer brought into collision.

In 1842 O'Connell started a great agitation for repeal of the Act of Union, and at one time seemed to be on the verge of driving the country into rebellion. O'Connell, however, had no such purpose, and when the younger and more fiery of his followers found this out they broke away from him altogether. O'Connell died while the horrors of the great famine of '46 and '47 were still on the land, and in the following year, 1848, the poetic, impassioned, ardently-sincere Young Ireland party broke or drifted into rebellion. The rebellion was easily put down—hardly a drop of blood was shed. But the Young Ireland movement had undoubtedly revived the national feeling in all its intensity. There was a 'Phoenix' conspiracy, as it was called, in 1858, and a Fenian movement in 1867. The existence and the succession of all these movements convinced men like Bright, and afterwards Gladstone, that there was much in the state of Ireland which called for reform and reconstruction. Gladstone set to work with characteristic energy. He disestablished and disendowed the Irish state church, a church which ministered to the spiritual wants of not quite one in five of the Irish population. He passed a series of measures to give better security of tenure to the Irish tenant-farmer, to entitle him to compensation for improvements he himself had made if he were to be ejected from his land, and to help to found a peasant proprietary in Ireland. A Land Commission—it might be called a Land Court—was formed, which had the power of reducing rents where reduction seemed necessary and rightful, and fixing the rent for a certain number of years. A Land Purchase Commission was created, the function of which is to assist tenants in buying their farms from the landlords, by an advance, under certain conditions as to repayment, of a large portion of the purchase-money. Meantime a fierce struggle had been raging between the peasantry and some of the landlords, the former supported

by the popular and powerful Land League. There was much disturbance in Ireland, and Coercion Act after Coercion Act was passed. A Home Rule party had been formed, and out of this party sprang a small but very determined body of Irish Nationalist members, who, under the leadership of Charles Stewart Parnell, a descendant of the Sir John Parnell already mentioned, set themselves to force the claim of Ireland on the attention of the English parliament and public by a system of persistent obstruction of all business in the House of Commons. The spirit of unrest came to a head when the Phoenix Park murders were committed by a gang of miscreants. The Home Rule agitation went on growing stronger, and at last, when a new Franchise Act had given a popular suffrage to Ireland as well as to England, the Home Rule party carried off eighty-six seats out of one hundred and three which made up the Irish representation (1885). Gladstone (q.v.) brought in his first Home Rule Bill in 1886, but this was defeated in the Commons by the united Conservatives and Liberal-Unionists.

In 1888 the Parnell Commission began its sittings, and in the following year came to an end with a verdict for the defendants. See PARNELL (C. S.). In the same year Parnell gained notoriety in a divorce case, but the Irish Nationalist party were at first inclined to remain under his leadership. Gladstone, however, intervened on the grounds that it would be impossible for the Liberals to work with the Nationalists for the cause of Home Rule if Parnell was still leader. At this the Irish party divided into two, the majority under the leadership of Justin McCarthy and the minority under that of Parnell. On Parnell's death in 1891 John Redmond became leader of the Parnellite party.

In 1893 Gladstone brought in his second Home Rule measure, which, passed by the House of Commons, was rejected by the Lords. In this year the Gaelic League for the revival of Irish as a spoken language was founded in Dublin, and the movement has since become a great success, and spread enormously over the country. In 1900 John Redmond was unanimously elected chairman of the united Nationalist party in succession to John Dillon, who had become leader on the resignation of Justin McCarthy. A great convention was held in Dublin, which set the seal on the union, and recognised the United Irish League as the great national organisation. From 1903 to 1912 a number of bills were passed in an endeavour to settle at least a part of the Irish trouble, but they were only partially a success. These included a Land Bill giving increased facilities for land purchase; the Town Tenants and Labourers Bill; the Irish Council Bill; and the Evicted Tenants Bill. These measures were undoubtedly a social success, but not the political success hoped for. Sinn Féin was founded by Arthur Griffith (q.v.). In 1912 Mr Asquith's Government of Ireland Bill was introduced. The Ulster Unionists, led by Sir Edward Carson (Lord Carson), thereupon pledged themselves by a 'Covenant' to use 'all means which may be found necessary' to oppose Home Rule, and to oppose a Home Rule parliament. Then the Ulster Volunteers were organised. The Nationalists replied by forming a Nationalist Volunteer force. Twice rejected by the Lords, the bill was passed over their heads (by means of the Parliament Act) in 1914. The question of amendment, however, by the exclusion of Ulster had not been disposed of—although a conference of party leaders had been held—when within a month of the outbreak of the Great War the situation in Ireland was briefly this: Two organised forces standing face to face, both protesting that their intentions were pacific

and at the same time refusing to change their position in the very slightest degree, a position which made any attempt at settlement impossible. The outbreak of war, however, changed the situation, and both parties declared their loyalty to the mother country. In September 1914 the bill became law, but a Suspensory Act postponed its coming into force till after the war. Sir Edward Carson announced that he would summon a provisional government in Ulster when peace was declared, and would use the Ulster Volunteers to prevent Home Rule from taking effect there. In 1915, however, he entered Mr Asquith's Coalition Cabinet. Redmond and his followers prepared to remain outside, while giving general support to the government. This situation favoured the rapid growth of a revolutionary Republican movement. Men were drilled in secret, and all the train was laid for an abrupt explosion, when on Good Friday 1916 it came to a head. Sir Roger Casement was captured on the west of Ireland in an attempt to land munitions, for which the rebels were waiting, from a German vessel. On Easter Monday the rebellion broke out in Dublin. The insurgents occupied Stephen's Green, the Post Office, the Four Courts, and other buildings, and proclaimed an Irish republic, with Patrick Pearse as provisional president. The actual rebellion was soon quelled, not, however, without much damage being done, but the movement grew. Mr Asquith, and afterwards Mr Lloyd George, sought to effect a compromise; an Irish Convention met (1917) to devise a scheme, but Sinn Féin refused to take part in it, and won a sweeping victory at the bye-elections. An attempt to introduce conscription, an attempt not followed through with any strength of purpose, lost England enormous prestige. On Redmond's death Mr John Dillon became leader of the Nationalists (1918). Their strength, however, was reduced to seven in the elections of 1919, against seventy-three Sinn Féiners. The latter, however, did not take their seats but met in Dublin, where as Dáil Éireann (the Parliament of Ireland) they elected De Valera president of an Irish republic, and a state of armed terror came to exist in the country. Indeed, the conflict became at times a contest of absolute cold-blooded murder. December 1919 saw the introduction by Mr Lloyd George of a bill to set up two parliaments in Ireland (one for part of Ulster), with a Council of Ireland, the two parliaments having power to establish a parliament for All Ireland. The country meanwhile was in turmoil—the British forces in opposition to the Sinn Féiners—and murder, arson, and pillage were rampant. At length in 1921 the British government saw that unless it were to declare a definite state of war in Ireland something definite must be done. A truce was thereupon called, and on 6th December 1921 a treaty was signed which gave dominion status to the twenty-six counties of Southern Ireland under the name of the Irish Free State, and a certain form of freedom to six counties of Ulster under the name of Northern Ireland. Ireland by this gained all the essentials of freedom, as the only important reservations made were those of allegiance to the king, and certain essentials demanded by the strategic and economic interdependence of the two countries. A provisional government was at once set up in Dublin with Griffith as president of Dáil Éireann, but De Valera with a hot-blooded minority broke away. Then instead of Irishmen fighting the men of Great Britain they began a furious and ferocious fight amongst themselves. At this point Griffith died suddenly, and Michael Collins, commander of the government forces, was murdered. The Free State government, however, showed commendable strength of purpose, and the armed intercession of a wild minority in her affairs was

brought to a close. In 1923 she was admitted a member of the League of Nations. Northern Ireland meantime had gone on her course, and had set up her own government and administration in Belfast. The fixing of the boundary remained a difficulty.

LANGUAGE AND LITERATURE.—The native language is Gaelic—Irish Gaelic as distinguished from Scottish and Manx Gaelic, the three constituting the Goidelic branch of the Celtic language (see GAELIC, CELTS). In Ireland the language was less subjected to corrupting influences than in Scotland and in the Isle of Man, and it was more carefully cultivated. The diction of Irish Gaelic is accordingly more copious, and the grammatical forms are fuller. The Norse language, which displaced for a time the native tongue in the Hebrides, hardly took root in Ireland. In the names of three of the four provinces the Norse suffix *ster* appears, but the Scandinavian element in Irish topography as compared with that of the north-west Highlands and the Isle of Man is very small. The English language found its way to the country in the 12th century, but for very many years its advance was slow. As is well known, several of the leading English settlers became ardent students and patrons of the native language and literature. Of the Burkes, the Butlers, the Keatings, and Geraldines it used to be said in this regard that they were *ipsis Hibernis Hiberniores*. Beyond the 'pale' the native laws and ways flourished in full vigour in the 17th century. And even in the more purely English districts Gaelic was commonly spoken. But for three hundred years English steadily and with ever-increasing pace gained ground. The seeds of decline of the native tongue were sown even earlier. The revival of learning which spread over the west of Europe in the 15th century hardly touched Gaelic territory. The impetus given to the cultivation of the native language in Wales and even in the Highlands of Scotland by the Reformation was scarcely felt in Ireland. The views of men in power were hostile to the study of Gaelic. The plantation of Ulster by James I., together with repressive measures afterwards adopted, checked the production of native literature and gave an impetus to the spread of English among the people. Within recent years increased facilities of communication with England, Scotland, and America; the advance of education;

the extension of the suffrage; the social and political movement of our own day—all contribute to the increasing use of the English language, but without reducing to the same extent the number of persons able to speak the old tongue. Within still more recent years national feeling has come to the help of scholarship in spreading a knowledge of Irish among the cultured classes. Many emigrants fondly cherish their mother-tongue in America.

The rich literature of Ireland has been preserved to us in inscriptions and manuscript. The oldest inscriptions, found in the south-west of Ireland, are written in a peculiar script called Ogam (q.v.). Native writers made occasional use of this primitive and withal clumsy mode of writing long after they became acquainted with the Roman alphabet, for we find specimens in such MSS. as the Priscian St Gall, and even in quite modern documents, as, e.g., in MS. XXXV. of the Scottish collection. A few of the Ogam inscriptions are bilingual, Gaelic and Latin, so that the readings of the unilingual Ogam are established. The oldest of them date as far back as 500 A.D. The linguistic forms would suggest even a higher antiquity. Thus, for example, the genitive of masculine O-stems ends in *i-magi*, *mailagni*, forms on the same platform with the Old Gaulish inscriptions *Ategnati*, *Dratieni*, and for that matter with classical Latin—*Maximi*, *domini*. The oldest MS. forms are *maicc* and *mailain*, the terminal *i* disappearing as a separate syllable, but becoming incorporated in the preceding syllable in order to preserve the sound of the consonant. Inscriptions in Roman characters are found with greater or less interruption down to our own day.

The MS. literature dates from the end of the 7th or the beginning of the 8th century. The Roman cursive hand of the 5th century was introduced by St Patrick and his companions into Ireland, and has been adhered to with characteristic tenacity to this day, but only eighteen letters were permanently adopted: *a, b, c, d, e, f, g, h, i, l, m, n, o, p, r, s, t, u*. *X* is used to express the numeral 10, occasionally to represent the combination *cs*; *q* stands for *cu*; *k* frequently for *ca* and *cath*, 'battle'; *y* and *z* are met with in one or two loan-words—*ymmon*, a 'hymn'; *Zephan*, 'Stephen'. The oldest preserved MSS. are in Latin. Over 200 dating from before the year 1000 still remain, all with the exception of some half-a-dozen in France, Germany, Switzerland, and Italy. They were written by Columbanus (q.v.), his companions and followers, or carried abroad during the 8th and 9th centuries.

One occasionally finds a Gaelic quatrain on the margin of these MSS., as in the Priscian St Gall, or a short poem on a blank page, as in the Milan and Carinthian Codices. There is a fragment of a sermon in old Gaelic in the town library of Cambridge; and still more valuable are the Annotations on the *Book of Armagh*, written in the early part of the 9th century. But the most important remains of old Gaelic are full glosses on about a score of the Latin MSS. on the Continent. Three such are specially noteworthy: a copy of Priscian's Grammar in the library of St Gall; a copy of St Paul's Epistles in the university of Würzburg; and a commentary on the Psalms by Columbanus, now in the Ambrose Library, Milan. The glosses on the Milan Codex are so voluminous that, according to Stokes, a very complete grammar and dictionary could be compiled from them alone. The oldest Gaelic MSS. now existing were written by the end of the 11th century. To this period belong two beautiful copies of the *Liber Hymnorum*, containing hymns in Latin and Gaelic

composed by the early saints, Patrick, Fiacc of Sletty, Columba, and others. The writer of *Leabhar na h-Uidhre*, 'the Book of the Dun Cow,' a miscellaneous compilation extracted from earlier books now lost, was killed in the year 1106. The *Book of Leinster*, a large folio of 410 pages, was written before 1167; the *Book of Ballymote*, also a large folio of 502 pages, and the *Leabhar Breac*, or 'Speckled Book,' containing 280 pages, by the end of the 14th century. Somewhat later are the *Book of Lecan*, a small folio of over 600 pages; and the *Yellow Book of Lecan*, a large quarto of 500 pages. The number of MSS. increases as we come later down. Many of the MSS. in the libraries of the Royal Irish Academy, Trinity College, and Franciscan Monastery, Dublin; in the Bodleian, Oxford; and in the British Museum are beautifully written; while several in the ornamentation of their capitals and margins are fine specimens of the artistic skill of the old Gaelic scribes. The contents embrace all departments of literature. A considerable part is translated or

Óir is mar ro do ghrádhúgh Dia an domhan, go dtug sé a éingheinn Meic fein, ionnus gídh bé chreideas ann, nach rachadh sé a mughá, achd go mbéith an bheatha shnorruidhe aige.

John, iii. 16 in Irish. The following is the transliteration in Roman letters; Óir is mar so do ghrádhúigh Dia an domhan, go dtug sé a éingheinn Meic fein, ionnus gídh bé chreideas ann, nach rachadh sé a mughá, achd go mbéith an bheatha shnorruidhe aige.

adapted. Such are the portions of the legendary history of Greece and Rome—the destruction of Troy, the wandering of Ulysses, the story of the Æneid, the life of Alexander the Great, &c.; most of the passions, homilies, and legends, scriptural and ecclesiastical, in the *Leabhar Breac* and other MSS.; and such also is the medical section of the literature. Of native production are history, including biographies, annals, and genealogies; tales, mythological, heroic, legendary; grammars and dictionaries; law; and poetry.

Modern Gaelic literature is scanty. The New Testament was published in 1603, and the Old in 1635. A fresh translation of the Pentateuch was made in 1868 by Archbishop MacHale, who also printed the first six books of the *Iliad* and a selection of Moore's melodies in Irish Gaelic. The New Testament has been translated anew by Mr Kane into the Munster dialect. Fugitive pieces of lyric verse have appeared from time to time. The *Reliques of Irish Poetry*, published by Miss Brooke in 1789, and the six volumes published by the Ossianic Society (1854–61), are chiefly 'Ossianic.' Brian Merriman (1757–1808) wrote a long poem, *Cúirt an mheadhoin oidhche* ('The Midnight Court'), in 1780. To the recent revival belong Dr Douglas Hyde, Irish scholar and folklorist (b. 1860); Canon Peter O'Leary (died 1920), novelist and translator; Pádraig O'Conaire, novelist.

Celtic scholarship dates from the publication of Zeuss's *Grammatica Celtica* in 1853 (ed. Ebel, 1871). Valuable work was, however, done by Eugene O'Curry in his *MS. Materials of Irish History* (1861) and *Manners and Customs of the Ancient Irish* (1873); and by O'Donovan in his *Grammar* (1847), his edition of the *Annals of the Four Masters*, and his *Supplement to O'Reilly's Dictionary*. Ebel and Schleicher and Ziegfried have been worthily succeeded by such men as Ascoli, Nigra, Windisch, Zimmer, Thurneysen, Jubainville, Loth, and Kuno Meyer on the Continent, and by Stokes, Rhys, Atkinson, and others. Pedersen's *Vergleichende Grammatik der Celtischen Sprachen* was completed in 1914. Windisch's *Kurzgefasste Irische*

Grammatik was translated in 1879. There are grammars of modern Irish by Joyce (1896), Henry and the Christian Brothers (1906), and a great dictionary by Dinneen (Irish Texts Soc. 1904). Important are Windisch's edition of the *Táin-Bó Cuailnge* (1906), and the text and translation of Keating's *History of Ireland* by Father Dinneen (3 vols. 1901-8). Zimmer (1881) and Stokes published the valuable Würzburg MS., with minor glosses; Nigra, the Turin glosses; and Ascoli, the St Gall and Milan codices. Copious extracts from the early texts were printed by Stokes under the title *Goidelica* (1872), by O'Grady in *Silva Gadelica* (1893), and Strachan (1904). The Irish Texts Society was established in 1898. Windisch examined the laws of *auslaut*, vocalic and nasal, and explained initial aspiration and eclipsis (the essay was translated by Cameron, and printed in the *Scottish Celtic Review*). Zimmer and Thurneysen investigated the position of the accent, and its influence on the development of sound and form in Gaelic. The laws of metre were discussed by Atkinson, Stokes, and the scholars above named; Stokes added to our knowledge of the Gaelic noun and verb; and see Strachan's *Old Irish Paradigms* (1905). Valuable materials for a lexicon were brought together by Windisch in the *Wörterbuch* appended to his *Irische Texte*; by Atkinson in the vocabularies printed with the *Homilies*, &c., from the *Leabhar Breac*, and with Keating's *Three Shaffs of Death*; by Zimmer in his *Keltische Studien*; and by Stokes in the full *Indices Verborum* attached to the numerous texts published by that great scholar. The life and civilisation of the people have formed the subject of separate treatises, as, e.g., O'Curry's *Manners and Customs of the Ancient Irish*, and Rhys's *Celtic Heathendom* (Hibbert Lectures for 1886); but more frequently of elaborate introductions and notes to the more important publications, such as Reeves's *Life of St Columba*; the Rolls Series; Stokes's *Calendar of Oengus*, *The Tripartite Life of St Patrick*, and *Lives of Saints* from the *Book of Lismore*.

See Joyce's *Old Celtic Romances* (1901); Kuno Meyer's *Selection from Ancient Irish Poetry* (1911); Eleanor Hull's *Text Book of Irish Literature* (1904-8); Douglas Hyde's *Literary History of Ireland* (1899); Best, *National Library of Ireland* (1914); P. Walsh, *Gleanings from Irish MSS.* (1918); and the periodicals *Ériu* (Dublin), *Zeitschrift f. celtische Philologie* (Halle), *Revue Celtique* (Paris).

Ireland's share in English literature includes, at its widest, descendants of distant Irish ancestors like the Brontës and Edgar Allan Poe, Anglo-Irish haters of Ireland like Swift and Thomas Parnell, and pure-blooded Englishmen born or domiciled in Ireland like Sterne and Charles Lever. As in political history, environment has counted for more than race. Mr W. B. Yeats, Mr J. M. Synge (1871-1909), Lady Gregory, Mr George Moore, and other poets, novelists, and dramatists of the so-called Celtic revival—a movement of more import in English than in Irish—have cultivated in English those qualities that are supposed to belong to the Celt. These, with Oscar Wilde, still await the verdict of posterity. Other Anglo-Irish poets, of whom there has been no lack since the days of Michael of Kildare (14th century) and Richard Stanihurst (1547-1618), no longer stand so high in reputation as they did with the contemporaries of Sir John Denham, of Thomas Parnell, and of Thomas Moore. There may be nothing distinctively Irish in the metaphysical clarity of Berkeley; but the Anglo-Irish temperament may plausibly claim to have endowed English literature with such varied forms of humour as appear in Swift, Goldsmith, Sterne, and Maria

Edgeworth; with the eloquence not only of Irish patriots like Grattan, Flood, Curran, and O'Connell, but of Burke and Canning; and with the vivacity and wit of the comedies of Farquhar, Steele, Sheridan, and Mr Bernard Shaw.

IRISH CHURCH. The Irish Church was a branch of the Celtic Church, which comprehended the churches of Galatia in Asia Minor, of Gaul, and of the original Celtic inhabitants of Great Britain and Ireland. The Celtic Church of Gaul necessarily exercised a great influence over the neighbouring islands.

St Patrick is called the apostle of Ireland, and his first missionary arrival is fixed at 432; but there were in all probability scattered colonies of Christians along the eastern coast of Ireland by the year 400. We have proof positive of the existence of Christianity in Ireland in the *Chronicle of Prosper of Aquitaine*, a contemporary of St Patrick. Prosper, under the date of 431, writes thus: 'Palladius was consecrated by Pope Celestine and sent to the Scots believing in Christ as their first bishop,' where the reader must observe that the name Scots or Scoti was till the 11th century exclusively applied to the inhabitants of Ireland. Palladius had not, however, much success in Ireland; he failed to convince the Irish, was driven northwards, and died in North Britain. Thus ended the first formal attempt to convert the Irish, an effort made too under the direct sanction and authority of the papal see. The very next year (432) St Patrick is said to have arrived on a similar mission; but he was better qualified for his work, and he made his influence felt in every part of Ireland. Gaul in the early part of the 5th century was the great European centre for eastern monasticism. At the very time that St Patrick landed in Ireland from Gaul there was a most active and continuous intercourse kept up between Gaul and St Jerome at Bethlehem, Nitria, and the monasteries of the Thebaid in Egypt. It is to be expected, then, that the Christianity introduced by St Patrick would exhibit traces of its eastern and especially of its Egyptian origin. The architecture and ecclesiastical arrangements of the early Irish Church have therefore many features in common with the East. The monks of Nitria and of the East were generally solitaries dwelling each in his own cell, even when living in a community and under an abbot. The Irish monks were solitaries too, and down to the present day their beehive huts, constructed so as to secure the least possible comfort for the inhabitants, remain all along the western coast of Ireland. The churches in Ireland are often grouped in sevens and placed within a cashel or stone fortification. So they are in Egypt (Butler, *Coptic Churches*, i. 14). The round towers, too, though not so old as St Patrick's time, came to Ireland from the East through Gaul and Ravenna.

The interval between the arrival of St Patrick and the invasion of Ireland by Strongbow and the Anglo-Normans (1169-72) is a celebrated one in the history of the Irish Church. The 6th and 7th centuries are its best-known epoch, for it was then that St Columba and St Columbanus lived and worked. The Irish Church at that time was the great missionary church of Europe. St Columba was its first great missionary. He was the apostle of the Scottish Highlands, and he summoned to his aid when dealing with the Picts two celebrated Irish saints—Canice the patron of Kilkenny, known in Scotland as Kenneth, and Comgall, the founder and first abbot of Bangor in the County Down. St Columbanus (q.v.) preached and taught in Gaul and Burgundy, in Switzerland, and in northern Italy. Other missions were those of Aidan, Colman, Finan, Cedd, and many others in northern and central England; of Virgilius, Marianus Scotus,

Cataldus, Fiaca, Fridolin, and several others in various parts of the Continent, down to the 12th century. All these men were not only great missionaries, but also, viewed by the standard of that day, great scholars. Virgil, the geometer and first bishop of Salzburg, was the first of moderns who taught the doctrine of the earth's sphericity and of the existence of the Antipodes. Columbanus upheld the old Easter cycle against Gaul and Rome combined. Sedulius and John Scotus Erigena knew Greek when a knowledge of it had died out elsewhere in the West.

This ancient church was monastic and yet episcopal. It was episcopal but not diocesan: its highest order were bishops but not prelates. The prelates or rulers were the heads of the monasteries, who might be bishops but were most often mere presbyters and abbots. St Patrick and the early missionaries from Gaul found Ireland intensely tribal. Every modern barony, of which there are some hundreds in Ireland, represents an ancient sept or independent jurisdiction. Every ancient diocese, some thirty or so in number, represents an ancient kingdom, or at least an ancient tribe. The earliest missionaries attached themselves to tribes, who looked to the monasteries and specially to the first founders of the monasteries, regarding them as the apostles of Ireland. But these missionaries had received Christianity in an episcopal shape, and so they retained it. The abbot exercised jurisdiction over all persons and ranks within his community. But the bishop or bishops who might be resident in the monastery or within its reach exercised episcopal functions, ordaining even the abbots themselves, and celebrating the eucharist in their presence. In the controversy as to the relation towards Rome of the early Irish Church some have insisted that St Patrick was simply a papal emissary. Others have insisted upon his complete independence. There cannot be much doubt, however, that Rome and Ireland were for long divided upon important questions. The controversies of the 7th century with respect to the mode of baptism, the keeping of Easter, and the method of the tonsure prove that, while the Irish Church of that date looked up with the greatest respect to the city where the blessed apostles Peter and Paul had suffered, yet she claimed independence in all matters of doctrine and ritual. The Celtic Church, whether in England, Ireland, or Scotland, made a stubborn resistance to Roman claims. In England and Scotland the resistance collapsed at an earlier period. But in Ireland the ancient national opposition to papal claims did not cease till the Synod of Kells in 1152, and of Cashel in 1172.

As to the ritual of the Celtic Church we have not much information. No ancient service-books have survived in Ireland, though a large number of manuscripts belonging to the Celtic period exist in the Dublin libraries; they are almost all, however, transcripts of the Gospels, as the Book of Kells, or of the New Testament, as in the Book of Armagh. The *Antiphonarium Benchorensis* and the Book of Hymns which Dr Todd published in the Irish Archæological series do not contain the liturgy properly so called—i.e. the service for the Holy Communion. It is most likely, however, that the missal of the Celtic Church was in the main identical with that of the other churches of the West, though there were special local usages most abhorrent to the ideas of the Roman party, till in 1172 the Council of Cashel finally established throughout Ireland conformity with the Church of England. There are two other points connected with the Church of Ireland which have often raised discussions—viz. the round towers and the Culdees system. But Dr Petrie has proved that the round towers are of Christian origin, that they were always

connected with monastic establishments, and used partly as belfries and partly as places of refuge and defence during the wars of the Danes; while Bishop Reeves has shown that the Culdees (q.v.) were spread all over the Celtic Church, and were only the ancient Celtic monks in a state of corruption.

The Roman system was striving for superiority in Ireland from the 7th till the 12th century. Malachy, Archbishop of Armagh (1134), saw that the ancient Celtic system was hopelessly corrupt. He visited St Bernard of Clairvaux, and could not but be struck by the contrast which his own church presented, devoid of architecture, order, or discipline, the prey of every rude and hostile chieftain, when compared with the Roman system in Gaul, where every rank was duly graduated, every order exercised its due functions, and the laity were humbly submissive to ecclesiastical decrees. St Bernard also about 1140 sent the Cistercians to Ireland, and they became the chief agents in reducing the Irish Church beneath the yoke of canonical obedience. The Cistercians brought notions of material civilisation, especially as regards agriculture and architecture, almost hitherto unknown; for, though the Celtic Church had cultivated literature and scholarship, the really ancient Celtic churches and monasteries were all of the humblest description so far as their architecture was concerned. Here and there indeed in Ireland, when the Cistercians came, a few specimens of architecture of a highly ornamental type called Hiberno-Romanesque were scattered; but it was the Cistercians who made splendid churches and monasteries fashionable in Ireland. The Cistercian monasteries rapidly spread as Anglo-Norman power advanced all over the island. Ireland within one hundred years after the invasion was more thoroughly conquered than she was three centuries later. The year 1250 saw the king's writ far better respected in Kerry or in Donegal than it was in the reign of Elizabeth, and wherever the Anglo-Norman barons settled they brought the Cistercians with them. De Burgh built St Thomas's Abbey in Dublin in honour of Thomas à Becket; De Lacy, Bective Abbey, overhanging the Boyne near Navan; Strongbow, the Marshals, and their friends erected Jerpoint and Dunbrody in the south; the De Courcys Newry and other abbeys in the north. The Cistercians assisted in other directions as well. The Synod of Cashel met in 1172 under the presidency of Christian, Bishop of Lismore, the papal legate of that day, and passed eight canons, enforced the payment of tithes, regulated the work of catechising and of baptism, established the Roman table of affinity in matrimonial matters, and decreed uniformity of worship throughout England and Ireland. From the date of this synod the canon law, as it was received in England, became law in Ireland. The last Celtic Archbishop of Dublin, Laurence O'Toole, died in 1180. The next archbishop, John Comyn, was an English courtier, nominated by Henry II., and from Laurence O'Toole till the Reformation no Irishman was ever Archbishop of Dublin.

The Anglo-Normans whenever they had power strove completely to exclude the Celts from ecclesiastical benefices, and whenever the Celts had power they strove to exclude the Anglo-Normans. In fact, from 1172 till 1540, there were two churches in Ireland, one Anglo-Norman, the other Celtic, bound together by the one tie, the papal supremacy. This hostility between Celt and Anglo-Norman appears again and again. Prior to 1220 the Anglo-Normans prohibited the admission of Irish clerks into monasteries or benefices under English dominion. The pope rebuked this exclusive spirit in bulls issued in 1220 and 1224. Later in the same century the prelates of the Celtic

portion of the church retorted with a decree prohibiting the admission of English clerics into parishes or monasteries under their jurisdiction. This spirit of division was embodied in the Statute of Kilkenny (1365), which peremptorily forbade the admission of Irish clerks into any benefice where English rule prevailed; and it continued to be the practical rule followed in all higher promotions till long after the Reformation. Dublin and Kilkenny were the great seats of Anglo-Norman power from 1172 to 1540. Both these districts are full of monuments of English church-building, following exactly the model of coeval English architecture; while one must penetrate far into the mountains of Wicklow, or else depart westward into the great central region of bog and morass, before a glimpse can be had of true Celtic architecture.

While, however, there was this internal national division in the Irish Church during this period, the doctrine, the ritual, and government of the church were uniform. The papal supremacy was universally accepted; the royal supremacy was equally respected. Throughout every part of Ireland, no matter how Celtic, whenever a bishopric fell vacant, license to elect was first humbly sought from the crown of England. And this was no empty ceremony, for whenever the see was of sufficient value the crown also took good care to signify its pleasure as to who should occupy it. The four archiepiscopal sees, Armagh, Dublin, Cashel, and Tuam, were almost always filled by Anglo-Normans. The Irish Church thus ceased to be a missionary and a learned and became a merely political church.

The national hatred which prevailed between the Anglo-Norman and Celtic portions of the Irish Church between 1172 and 1540 explains the history of the Reformation period. The English portion of the population naturally followed the changes in England, and the Celts as naturally held all the more firmly to the papal supremacy and the old state of things which had now become synonymous with hostility to England. Romanism and nationalism became now and henceforth close allies in Ireland, though previously the pope had been almost always found hostile to the Celts. During the years between 1528 and 1600 the course of change in England was simply reflected in Ireland. Archbishop Alan, an English ecclesiastic who occupied the see of Dublin in 1528, was a friend of Wolsey; and he followed closely his patron's footsteps. About 1528-36 forty of the smaller Irish monasteries were dissolved by him. In 1536-38 the remainder were suppressed and their property granted to the king, who disposed of it to various noblemen and courtiers. The work of reformation now advanced *pari passu* in England and Ireland. During the reigns of Mary and Elizabeth the Irish Church, so far as it was under English influence, humbly followed the changes in England: under Mary the papal supremacy was acknowledged, and the Latin mass celebrated; under Elizabeth the royal supremacy was alone legal, and the English liturgy was used. In the Celtic districts during Elizabeth's reign a number of bishops commissioned by Rome, aided by several Jesuits, maintained under great difficulties a vigorous opposition to the Reformation. The 17th century saw new elements of religious confusion introduced. The immigration of the Scottish Presbyterians and the settlement of Ulster brought a community into Ireland who disliked the episcopal establishment almost as much as the Pope's adherents. They naturally sympathised with the Puritan opposition in England, which culminated in the supremacy of Cromwell. During his vigorous rule, which secured for Ireland a greater amount of peace than she had

long known, the episcopal establishment was subverted, and an establishment of a congregational type erected in its stead. On the Restoration the episcopal establishment was restored in greater splendour than ever.

The Roman Catholics now began to consolidate their organisation, establishing a regular succession of resident bishops and clergy throughout the whole country. After the Revolution of 1688-91 a series of stern enactments commenced, which grew more and more severe till the reign of George II. These penal laws were directed against the Roman Catholics, partly as adherents of the Pretender and partly in revenge for the persecution of the Huguenots (q.v.), many of whom took refuge in Ireland. They began to be relaxed during the earlier half of the reign of George III. In fact all through his reign the Roman Catholic Church exercised openly all its functions and maintained a regular episcopal succession. In 1829 the act of Catholic Emancipation (q.v.) was passed, which swept away all disabilities affecting the secular clergy of the Church of Rome, though still retaining certain restrictions upon the regular orders. By the act of Disestablishment, passed 26th July 1869, the state has separated itself as far as possible from interference in the affairs of any branch of Irish Christianity. The former Established Church is now governed by a general synod, which meets annually in spring, composed of the bishops and representatives of the clergy and laity; while the Roman Catholic Church is ruled, as formerly, by the bishops acting under the direction of the pope. Irish Presbyterianism, dating from 1613, prevails especially in the eastern parts of Ulster. The Presbyterians of Ulster were till 1869 endowed with a *Regium Donum* (q.v.). The organisation of the Presbyterian Church dates from 10th June 1642, when the first presbytery was established in Carrickfergus.

See, among older authorities, Ussher's Works; Sir James Ware's Works (ed. Harris); Colgan's *Acta Sanctorum Hib.*; *Annals of Four Masters*, and works in Rolls series, as *Chronicon Scotorum* and *Annals of Lough Cé*. In the 19th century, Todd in his *Life of St Patrick*, and R. King in his *History of the Irish Church*, maintain the Protestant view; Cardinal Moran, in *Essays on the Early Irish Church*, the opposite view; Lanigan, in his *Ecclesiastical History of Ireland*, an intermediate position. Dr Reeves in his *Adamnan's Life of Columba* and other works has thrown floods of light on the subject. Other authorities are E. Hogan, S.J., *Documenta de S. Patricio*; Whitley Stokes, *The Tripartite Life of St Patrick*; Warren, *Celtic Liturgy*; Skene, *Celtic Scotland*. G. T. Stokes in *Ireland and the Celtic Church* (1886), and *Ireland and the Anglo-Norman Church* (1889), maintained the independence of the Irish Church; Bellesheim (1890) defended the opposite view. See also Plummer's *Vita Sanctorum Hibernie* (1910); D'Alton, *History of Ireland* (1904-10); Bishop Healy of Clonfert, *Schools and Colleges of Ancient Ireland* (1890); Wasserschleben, *Die Irische Kanonensammlung* (1885); Olden, *The Holy Scriptures in Ireland One Thousand Years Ago* (1888); T. K. Abbott, *Versio Ante-Hieronymiana*; Gilbert, *Facsimiles of the National MSS. of Ireland*. For the more recent history: Mant, *History of the Church of I.*; Hogan, *Hib. Ignatiana*; Reid, *History of the Presbyterian Church in I.*; Cotton, *Fasti Eccl. Hibern.*; D'Alton, *Archbishops of Dublin*.

Ireland, JOHN, English composer, born in 1879. After a training at the Royal College of Music he became organist at St Luke's, Chelsea. His published work, which includes many songs, began with *Phantasy*, a trio for piano and strings (1908). The *Forgotten Rite*, for orchestra, appeared in 1913, and in the following year *Decorations*. A sonata in E, and *London Pieces* (1920) are other works of this most prolific composer.

Ireland, SAMUEL WILLIAM HENRY, the author of the notorious Shakespeare forgeries, was

born in London in 1777, the son of Samuel Ireland, a dull and credulous, but honest dealer in old books and prints, and author of a few books of travel illustrated by himself. After some years' schooling in France the boy was apprenticed at seventeen to a London conveyancer, and ere long was tempted by his father's unintelligent enthusiasm for Shakespeare to forge an autograph of the poet on a carefully-copied old lease. His audacity grew with the growing credulity of his dupes, and ere long locks of hair, private letters, annotated books, &c., were plentifully produced, and all inquirers into the how and the where fubbed off with lying explanations. Boswell, J. Warton, Dr Parr, and hundreds more came, saw, and believed; but those, like Malone, really qualified to judge denounced the imposture almost from the first. Ireland's audacity now reached the folly of producing a deed of Shakespeare's bequeathing his books and papers to a William-Henry Irelande, an assumed ancestor. Next a new historical play entitled *Vortigern* was announced, and carefully concealed until its production by Sheridan at Drury Lane. It was rapid, worthless, and un-Shakespearean, and was hopelessly damned at once, and this fate nipped in the bud the growth of a projected series of historical plays, of which indeed that on Henry II. had already been written. He published a confession in 1796, and more fully in his *Confessions* in 1805, and soon sank into obscure poverty, eking out a miserable living as a bookseller's hack, till his death on 17th April 1835.

Ireland Island, one of the Bermudas (q.v.).

Irenæus, one of the most important of the ante-Nicene Christian writers, was probably born near Smyrna, in Asia Minor, between 120 and 140, and in his early youth was acquainted with Polycarp; but he is known in history solely through his connection with the Græco-Gaulish Church of southern France, of which he was a bishop. He was a priest of the church of Lyons, under the Bishop Pothinus, upon whose martyrdom, in the persecution of Marcus Aurelius, in 177, he was himself elected to the same see, which he continued to govern for twenty-five years. Gregory of Tours states that he suffered martyrdom in the persecution under Severus in 202; but this is probably a mistake. His day is the 28th of June. Irenæus was a devoted and successful missionary bishop, but his name is associated chiefly with his activity in opposing the Gnostics, and especially the Valentinians, and with his attempts to prevent a rupture between the Eastern and Western Churches over the question of the day on which Easter was to be kept. The lost *Demonstration of the Apostolic Teaching* was discovered (in Armenian) at Erivan in 1904, and has been translated, with introduction, &c., by Dr Armitage Robinson (1920). The only other work of his which has come down to us, except a few fragments, is his treatise *Against Heresies*; and even that, apart from fragments, we have only in a barbarous Latin version. The first edition of this work was published by Erasmus (1526), from three MSS. which have since been lost. There is a translation, including the fragments, in Clark's *Ante-Nicene Library*. See *Novum Testamentum S. Irenæi*, ed. Sanday and Turner (1923); a study by F. R. M. Hitchcock (1914); and for an able examination of Irenæus's opinions Dr Werner's *Der Paulinismus des Irenæus* (1890).

Irene, a poor orphan girl of Athens (born about 752), whose beauty and talents excited the admiration of the Emperor Leo IV., who married her in 769. After the death of Leo in 780 she ruled as regent during the minority of her son, Constantine VI. Banished to Lesbos in 802, she died there the next year. The Greek Church, on account of her

zeal for image-worship, counts her among its saints. See BYZANTINE EMPIRE.

Ireton, HENRY, an English general of the period of the Commonwealth, was the eldest son of German Ireton, of Attenborough, Nottingham, and was born in 1611. He studied at Oxford and at the Middle Temple, London, and on the breaking out of the Civil War offered his services to the parliament. His connection with Cromwell, whose daughter Bridget he married in 1646, greatly advanced his interests. At Naseby he was taken prisoner by Rupert, but Cromwell's charge set him at liberty. Ireton was one of the most implacable enemies of the king, and signed the warrant for his execution. He accompanied Cromwell to Ireland, and in 1650 became lord-deputy. On 26th November 1651 he died of the plague after the capture of Limerick. From Westminster Abbey his remains were transferred at the Restoration to Tyburn.

Iridaceæ, or IRIDEE, a natural order of monocotyledons, mostly herbaceous, with bulbous, tuberous, or creeping root-stocks; a few are somewhat shrubby. The leaves are generally sword-shaped, in two rows, and *equitant* (so placed that one seems to ride on the back of another). The perianth is 6-partite, coloured, often very beautiful, in some regular, in others irregular. The stamens are three, with anthers turned outwards. The ovary is inferior; there is one style, with three stigmas, which are often petal-like, and add much to the beauty of the flower. The fruit is a 3-celled, 3-valved capsule. About 800 species are known, of which the greater number are natives of warm countries. They are particularly abundant in South Africa. A few are British. Iris, Gladiolus, and Crocus are familiar examples of the order. Acridity is a prevailing characteristic, and some species are medicinal; but the corms and root-stocks of some are edible.

Iridescence, the sheen of mother-of-pearl and other objects possessing a finely-grooved surface. It is due to Interference (q.v.) between the waves of white light reflected from different levels in the grooving; some of the wave-lengths are more completely abolished by interference than others are; the result is that the residual vibration which reaches the eye contains a preponderant proportion of the rays which have been less affected by interference, and the reflected light accordingly presents colours which vary according to the angle of reflection.

Iridium (sym. Ir; atomic weight, 193; atomic number, 77; sp. gr. 22.38) is one of the so-called noble metals. It is occasionally found native and nearly pure in considerable masses among the Uralian ores of platinum, but is usually combined with osmium as an alloy in flat scales. It is a very hard, white, brittle metal, which may be melted by the oxyhydrogen blowpipe, or by the heat of a voltaic current. It is malleable at a white heat. In its isolated form it is unacted upon by any acid or by aqua regia, but as an alloy it dissolves in the latter fluid. It forms two oxides, Ir₂O₃ and IrO₂, and three series of salts distinguishable by their colours, usually much less soluble than the corresponding platinum compounds. Three sulphides and chlorides are obtainable. Iridium may be fused with phosphorus, becoming as hard as before, and is used for pen points, contact points in telegraphy, and wearing parts of scientific instruments. Iridium was discovered by Descotils and by Tennant in 1803.

Iris (originally a personification of the rainbow), the messenger of the gods in the *Iliad*, an office which belongs to Hermes in the *Odyssey*, was daughter of Thaumás and Electra, and sister of the Harpies. In the earlier poets she is a virgin god-

dess, but later writers make her wife of Zephyrus, and mother of Eros. She is frequently represented on vases and in bas-reliefs as a youthful winged virgin, dressed in a long tunic, with a herald's staff and a pitcher in her hands.—The broad coloured ring in the eye is called the Iris (see EYE). Iris is also the name of one of the minor Planets (q.v.), discovered in 1847.

Iris, or FLOWER-DE-LUCE, a numerous genus of plants of the natural order Iridaceæ, having the three outer perianth leaves reflexed, the three inner arched inwards, and three petal-like stigmas covering the stamens. The species are widely spread over the northern hemisphere. The Yellow Iris or Corn-flag (*S. Pseudacorus*) is abundant throughout Britain, and is readily distinguished from the Stinking Iris (*I. fetidissima*) by its larger and bright yellow flowers. The latter has violet-blue or rarely pale yellowish-white flowers, and the leaves smell disagreeably when bruised. The flowers of most of the species are beautiful. Some of them have received much attention from florists, particularly *I. Xiphium*, sometimes called Spanish Iris; *I. xiphoides* or English Iris; and *I. germanica* or Common Iris, all European species.

Yellow Iris (*Iris Pseudacorus*):
a, seeds.

Many fine varieties have been produced. The Persian Iris (*I. persica*), the Snake's-head Iris (*I. tuberosa*), and the Chalcedonian Iris (*I. susiana*) are also much esteemed. The Persian Iris is delightfully fragrant. The roots of all these species are annually exported in considerable quantities from Holland. Many other species are of frequent occurrence in flower-gardens. The Central Asiatic *I. tenuifolia* has been got at 4200 metres on Mount Everest.—The fresh root-stocks of *I. Pseudacorus* are very acrid, as are those of many other species. Those of *I. florentina*, *I. pallida*, and *I. germanica* are Orris Root (q.v.). Those of *I. dichotoma* are eaten in Siberia; those of *I. edulis* at the Cape of Good Hope. See W. R. Dykes, *The Genus Iris* (1913).

Irish Brigade, a force famous in the French service, may be traced to the bodyguard of the great Duke of Ormond during his viceroyalty. Re-formed at the Restoration from elements Charles II. had gathered in exile, the regiment of Irish guards fought for James II. at the Boyne and at Aughrim, and after the siege of Limerick passed as a body into the French service. Under various names (Dorington's, Dillon's, Roscommon's) it distinguished

itself at Malplaquet, Dettingen, and Fontenoy. Its officers were exiled Irish gentlemen, its ranks recruited from the 'wild geese' who fled from the Irish Penal Laws. At the Revolution, Walsh and his officers refused to desert the lilies for the tricolour; in 1794 the three remaining regiments passed over into the service of the British government, then in alliance with the Bourbons. The corps was sent to America under its old title, but soon ceased to exist, as recruiting in Ireland had become impossible; by 1798 the Irish had learnt to look to revolutionary France for help, and the Irish-French royalist officers returned from exile to find themselves regarded as renegades by their own people, and treated with ingratitude and bad faith by the British government. See Litton Falkiner's *Illustrations of Irish History* (1904).

Irish Elk, Moss. See ELK, CARRAGEEN.

Irish Sea, between the north of Ireland, the north of England, and the south-west of Scotland, is about 150 miles long and broad, and is connected with the Atlantic on the north-west by the North Channel and on the south by St George's Channel.

Iritis, inflammation of the iris. See EYE.

Irkutsk, a government of eastern Siberia (q.v.), bordering on China, has an area of 280,000 sq. m., and a pop. of 800,000 Buriats, Tunguses, and Russians.

IRKUTSK, the capital, on the Angara, was the residence of the governor-general of eastern Siberia and the seat of a bishop. Irkutsk is the best-built town in Siberia, with straight, wide streets and handsome public buildings. It possesses a cathedral, several churches, a public library, a museum of natural history, an observatory, and other public institutions. The pop., 32,512 in 1875, has increased to about 100,000; it consists mostly of Russians and Buriats. Irkutsk was founded by a Cossack chief, Ivan Pochabof, in 1652, and obtained town-rights in 1686. It is the commercial centre of Siberia, especially for the tea-trade. The Angara constitutes the main highway for goods bound for Kiakhta across Lake Baikal, as well as for those coming from eastern Siberia and China for Russia. The communications between Irkutsk and Yakutsk and the northern parts of Siberia are carried on by the river Lena. Irkutsk is an important station on the great transcontinental Siberian railway. It was occupied by the Czechoslovaks, who were fighting against the revolutionists.

Irmin was a Germanic god, fabled ancestor of the Hermiones. To him was dedicated the Irminsul (Irmin Pillar) at Eresburg (now Marsberg in Westphalia), a fortress of the Saxons and centre of their religious rites, which was destroyed by Charlemagne in 772.

Irnerius, the 'Lucerna Juris,' a learned jurist born in Bologna, who flourished there as a teacher of the liberal arts, and died before 1140. One of the earliest to devote serious study to the *Institutes* and *Code* of Justinian, he has been (some think without reason) regarded as the founder of the Bolognese school of law. His name also occurs in the forms Guarnerius and Warnerius. See his *Summa Codicis*, edited by Fitting in 1894, and Fitting's *Anfänge der Rechtsschule in Bologna* (1888).

Iron and Steel. It is scientifically impossible to separate these two substances. They will therefore be dealt with as sections of one subject.

Pure Iron.—Sym. Fe (*ferrum*), atomic number 26, atomic weight 55.8, sp. gr. 7.9. Nearly chemically pure iron is manufactured on a commercial scale in the form principally of finished tubes by the electrolysis of its ferrous salts and mixtures of them. By annealing electrolytic iron at 900° C. out of contact with air much of the occluded gas which it invariably

contains is expelled, and the mechanical strength of the material is also increased considerably. When pure iron is allowed to cool slowly from its melting point (1505° C.), heat is evolved at 1400°, 900°, and 760° C., and corresponding absorptions of heat are noticeable at or about these temperatures on heating up gradually from ordinary temperatures. These so-called critical points are designated by the symbols A_1 , A_2 , and A_3 on cooling, and A_1 , A_2 , and A_3 on heating. According to the hypothesis most generally accepted, the energy changes occurring at the critical points mark changes from one allotropic form of the metal to another, and there are thus four allotropic modifications of iron: δ -iron above 1400° C., γ -iron between 900° and 1400°, β -iron between 760° and 900°, and α -iron below 760°. The greatest of the four evolutions (or absorptions) of heat occurs at 900°, and when iron is heated up through this point a complete recrystallisation takes place, accompanied by a contraction in volume. The γ -iron thus formed is capable of taking carbon in the form of iron carbide, Fe_3C , into solid solution, whereas β -iron and α -iron exhibit little or no solvent power. When rapidly cooled by quenching in cold water the solid solution acquires a degree of hardness depending within limits upon the amount of carbide in solution; it is, in fact, the essential constituent of hard steels, being the cause of their hardness. 760° C. is sometimes called the magnetic change point, as it corresponds to the appearance of magnetic properties on cooling, and their disappearance on heating. Little is known with certainty about δ -iron. Like the majority of metals, pure iron crystallises in forms belonging to the cubic system; its hardness is approximately 4, that of fluor-spar, on Mohs's scale.

Pig-iron, Cast-iron, and Wrought-iron.—The foregoing denominations are trade terms, and have reference respectively to the crude iron tapped from a blast-furnace; to the remelting of the blast-furnace product in a cupola and its subsequent casting into various commercial forms; and to the purification of the crude pig to commercially pure iron. In tapping from the blast-furnace the molten stream runs into a channel, fashioned in sand, called the 'sow,' and from this channel numerous lateral branches, known as 'pigs,' receive the bulk of the 'tap.' In their nature the big 'sows' and the relatively little 'pigs' they have fed are of almost 'infinite variety,' which in the space-limit of the present article must be represented by three types—viz. (a) Swedish pig, (b) hæmatite pig, (c) phosphoric pig.

(a) *Swedish Pig.*—This crude iron may well claim to have been an important factor in the shaping of human destiny in the 'iron age'; statesmen may smile, but the fact remains. The advancement of ferrous metallurgical art and science is inseparably connected with the advance of what is now the chief city of the county of York—Sheffield. The position of Sheffield is largely due to the metallurgical art and science of Sweden, so far as iron and steel metallurgy is concerned. Steel (or steely iron) in the early history of the British Isles was used mainly for the purposes of cutting the earth (as in the arts of peace) or the bodies of the animals on the earth (as in the chase or war). As was quite natural, human animals also endeavoured to protect their bodies against steel with steel. In this connection, however, British steel in the

Norman period seems to have taken a 'back-seat.' In fact, whilst Spain and Italy had entered the 'steel age,' England still lingered in the 'iron age.' Perhaps no better example of this can be found than a quotation from Scott's *Ivanhoe*, in which, in describing the siege of Torquilstone, he writes: 'Thrice did Locksley bend his shaft against De Bracy, and thrice did his arrow bound back from the knight's armour of proof. "Curse on thy Spanish steel-coat," said Locksley; "had English smith forged it, these arrows had gone through as if it had been silk or sendal."' There is clear historical evidence that the basis metal of fine steel was obtained from abroad, especially from Sweden, although, curiously enough, the Swedish basis iron was known as 'Danske,' or Danish, just as at the present time much Danish butter is of Swedish origin.

The accounts of the Sheffield Church Burgesses show that in 1557 Swedish bar-iron cost 12s. per one hundred pounds. It is therefore necessary to consider the sequence of the production of Swedish pig and wrought irons as processes preliminary to the production of fine cutting steels. The source

Fig. 1A.

Fig. 1B.

Blast-Furnace.

from which all these products are derived is magnetite, or black iron ore, the loadstone of fable. This substance has the theoretical formula, Fe_3O_4 , expressed empirically, or constitutionally it may be written (FeO, Fe_2O_3) , being a compound built up of one molecule of ferrous oxide, FeO , and one molecule of ferric oxide, Fe_2O_3 . As a matter of fact, the massive veins of magnetite found in Sweden (e.g. at the mines of Dannemora and Persberg) contain impurities—chiefly silica, SiO_2 , and alumina, Al_2O_3 , which bring down the contents of metallic iron from the 72.4 of theory to about 60 per cent. net metallic iron. The ore is mined in the ordinary way, the large pieces of magnetite being separated on the bank by hand, whilst the small stuff is freed from vein stuff by a process of magnetic separation. The next operation is that of calcining, which is carried out with two objects: (1) to 'crozzle,' or render the dense ore more porous; (2) to evolve part of the sulphur existing as iron pyrites, FeS_2 , as SO_2 gas. The calcination is carried out in iron or mild steel stoves lined with firebricks, and heated by the waste gases of the blast-furnace. After calcination the ore is often 'weathered'—i.e. stacked in the open to expose it to the action of rain so as to wash out sulphur existing as SO_3 in the form of soluble sulphates.

The ore is now ready for smelting in the blast-furnace. This furnace is essentially a large steel tube lined with refractory bricks. The bottom of the double conical lining narrows to the 'well' for receiving the reduced iron. Above the well air is blown into the furnace through tubes *h h*, called 'tuyères' (see figs. 1A and 1B). In Sweden the charge is small, only about four tons being tapped at a time. It consists of the prepared magnetite, with charcoal for fuel and limestone (essentially CaCO_3) for flux. Speaking broadly, the furnace reactions may be described thus. The air blown through the tuyères comes into contact with the white-hot charcoal, forming momentarily CO_2 , or carbon dioxide gas, thus: $\text{C} + \text{O}_2 = \text{CO}_2$. But CO_2 in the presence of carbon at a white heat acts thus: $\text{CO}_2 + \text{C} = 2\text{CO}$, or carbonic oxide gas. Carbon monoxide is thus only half-saturated with oxygen, and on ascending the furnace at a low red heat at the top of the conical shaft it permeates the magnetite, and deoxidises it thus: $\text{Fe}_3\text{O}_4 + 4\text{CO} = 4\text{CO}_2 + 3\text{Fe}$. The spongy iron, still mixed with the earthy impurities of the ore, descends the furnace, and in the zone of fusion melts. The flux combines with the earthy matter, forming a fluid slag consisting essentially of a double silicate of lime and alumina. The molten iron, however, before reaching the bottom of the well has taken up about 6 per cent. of impurities, chiefly carbon and silicon. Dependent upon the working of the furnace, three distinct types of crude or pig iron may be produced, having in round numbers the following approximate compositions:

	Gray Iron.	Mottled Iron.	White Iron.
Combined carbon	0.40	2.00	3.60
Graphite, or Free carbon	3.60	2.00	0.40
Silicon	1.00	0.60	0.20
Manganese	0.30	0.30	0.30
Sulphur	0.02	0.02	0.02
Phosphorus	0.02	0.02	0.02

Broadly speaking, the production of gray or white iron is determined by two causes, one thermal and the other chemical. The higher the tapping temperature and the higher the percentage of silicon present the greater the tendency to produce gray iron, and the lower the initial temperature and the silicon the greater the tendency to produce white iron. It is obvious from the analysis given that the character of the iron is ultimately determined by the form in which its carbon exists. In gray irons nearly all the carbon is in a state of mechanical mixture, being scattered through the mass of iron in the form of flakes of free carbon, or graphite, the so-called 'black lead.' In white iron nearly all the carbon is chemically combined with the iron in the compound, Fe_3C , normal carbide of iron, containing nearly 6.7 per cent. of carbon. This compound has a hardness nearly equal to quartz, or 7 on Mohs's mineral scale. Hence the hardness and brittleness of white iron as compared with the softer and tougher gray iron, in which the carbon has very little chemical influence. The tenacity of iron as recast from pigs varies from about 6 to 18 tons per square inch. Its average tenacity is thus about 12 tons, but its ductility is practically *nil*. In compression, however, cast-iron is strong, and it may readily be obtained of such quality as to resist a crushing stress of 40 tons per square inch.

Swedish Wrought-iron.—Wrought-iron is the product obtained by the removal of carbon, silicon (and manganese) from pig-iron. In the case of Swedish wrought-iron these elements are reduced to a total of about 0.25 per cent. The process is carried out in Sweden by one of two methods—(a) in the Walloon hearth; (b) in the Swedish Lancashire hearth. These methods differ in details rather than in chemical principles.

In the Walloon process, D-shaped pigs, weighing three-quarters of a ton, are used. The pig is purified in a blast of air blown into a charcoal hearth, and eventually a sponge of iron (mixed with slag like plums in a pudding), weighing about seventy pounds, is obtained and hammered out into bars, about 10 feet long, 3 inches broad, and $\frac{1}{4}$ inch thick.

In the Lancashire hearth process, slab pigs, each weighing about three-quarters of a hundredweight, are employed, and the sponge obtained weighs about 200 lb. In either process the quality of the iron is injured if the iron-worker allows any dissolved oxygen to get into his sponge. So far as ordinary chemical analysis is concerned, both the Walloon and 'Lancash.' irons register identical results for properly wrought iron. The composition is approximately as follows:

Combined carbon	0.050
Silicon	0.030
Manganese	0.100
Sulphur	0.010
Phosphorus	0.015
Iron by difference	99.795

The silicon, however, is not combined with the iron, but with the involved slag in form of a basic ferrous silicate, containing perhaps 65 per cent. of FeO . This basic cinder is drawn out by hammering or rolling into streaks which constitute the so-called 'fibre' of wrought-iron. All wrought-iron is essentially crystalline, and 'fibres' of iron exist only in the imagination of engineers. The remarkable change in the mechanical properties of the crude iron brought about by the removal of nearly all the impurities therefrom is exemplified in the following table:

Product.	Tenacity, Tons per Square Inch.	Elongation per cent.	Reduction of Area per cent.
Pig-iron	12.0	0.0	0.0
Wrought-iron ..	20.0	45.0	75.0

(b) **Hæmatite Pig.**—As the source of fine cutting steel is the magnetite of Sweden, so is the source of acid structural steel for engine parts, bridge and ship plates, guns, armour, and projectiles the red hæmatite ore of West Cumberland and North Lancashire. This ore, which has the ideal formula Fe_2O_3 , occurs in huge pockets in the limestone. Theoretically this formula corresponds to 70 per cent. of metallic iron, but impurities (mainly, again, SiO_2 and Al_2O_3) bring the net iron content down to about 55 per cent. of metal. This ore is smelted in furnaces much larger than those of Sweden, the fuel being coke and the flux limestone. The ore is generally smelted in hot-blast furnaces as mined. The quality of iron produced is remarkably diversified. The involuntary variations of a hæmatite furnace are classified by fracture in as many as seven 'numbers'—viz. Nos. 1, 2, 3 are known as 'Bessemer irons, mixed numbers'; there are also Nos. 3, 4, 5 foundry irons; and a similar set of forge irons, and, finally, mottled and white irons, which might be called respectively Nos. 6 and 7. Speaking generally, it may be said of the products of a hæmatite blast-furnace that as the numbers rise from 1 to 7 the total carbon falls from 4 to 3 per cent. As the numbers rise, the free or graphitic carbon falls till, in white iron, the 3 per cent. of carbon present is almost entirely in the combined state as Fe_3C . As the numbers rise, the silicon falls from, say, 3 to 0.3 per cent. The manganese is steady at about 0.3 per cent. The phosphorus averages about 0.035 per cent. But a vital feature is the sulphur, which rises with the numbers—e.g. No. 1, or full-gray iron, may contain as little as 0.01 per cent. of sulphur; whilst No. 7, or white iron, contains about 0.2 per cent. sulphur, and is hence unfit for making acid

steel. The term 'acid steel' signifies a steel made in a furnace lined with anhydrous silicic acid, SiO_2 . It also signifies a steel made from hæmatite iron very low in sulphur and phosphorus. Therefore acid-steel makers will not buy iron above No. 3, as it is certain that the sulphur in high numbers will also be high, and injure the steel made therefrom.

(c) *Phosphoric Pig*.—Phosphorus occurs in iron ores generally as calcium phosphate, $\text{Ca}_3(\text{PO}_4)_2$, which is reduced in the blast-furnace, practically the whole of the phosphorus entering the metal, forming iron phosphide, Fe_3P . When the amount of phosphorus is comparatively large, the product is known as 'phosphoric pig,' from which basic steel is obtained (*vide infra*). Various ores are smelted, after being previously calcined. The

Fig. 2.—Puddling-Furnace, vertical section.

chief of these (and the most important of British iron ores) is clay iron-stone, which consists essentially of ferrous carbonate, FeCO_3 , mixed with more or less clayey matter. The calcining process eliminates CO_2 , converting the carbonate into oxide. The iron content of clay iron-stone varies

Fig. 3.—Puddling-Furnace, horizontal section.

from 20 to 37 per cent. Notts, Derby, S. Staffs, N. and S. Wales, and the Cleveland district of N. Yorks are the principal British manufacturing centres, whilst German and Belgian structural steel is also almost entirely of basic origin. The chemical reactions involved in the reduction of calcined clay iron-stone are substantially those

described previously for the purer ores. A typical charge consists of $2\frac{1}{2}$ tons of calcined ore, 1 ton of coke, and 10 cwt. of limestone per ton of iron made. The temperature of the blast varies from 500° to 700° C., and its pressure from $3\frac{1}{2}$ to 5 lb. per sq. in. Modern blast-furnaces have much greater capacity and output than formerly was the case. They may have a height of 100 feet or more, with a diameter of 30 feet at the boshes; with continuous working an output of 2000 tons of pig-iron per week is not infrequent.

English Wrought or Malleable Iron.—This famous product, once produced in very large quantities in Yorkshire and South Staffordshire, has been to a great extent ousted by mild steel. As will be shown later, the term 'malleable' is liable to lead to confusion. Wrought-iron is prepared by an essentially basic process, the hearth upon which it is made being the basic oxide, Fe_2O_3 , in some form.

The puddling-furnace is shown in vertical section in fig. 2. *b* is the bed, *f* the flue, and *pppp* iron pillars supporting the furnace. It is constructed of firebricks; and the whole, excepting the flue, is encased in iron plates strapped together by iron rods. *f* is the fireplace, *br* the bridge. When the fire is blazing, the flame strikes the arched roof beyond the bridge and 'reverberates' down upon the contents of the bed, and then passes to a chimney, the draught of which is regulated by a damper. Fig. 3 is a horizontal section with the same lettering, except that *s* is added to show the working-door. When the furnace is hot, the puddler 'fettles' the bed and sides with ground oxide of iron. A charge of pig-iron weighing about four hundred-weights is now melted on the oxide hearth. The molten metal is then 'rabbed' with a giant hoe. The boil, due to the evolution of CO gas, is next reached, and as the carbon, silicon, phosphorus, and sulphur are removed the mass thickens or 'comes to nature,' and is 'balled up' into three masses of iron-sponge mixed with basic cinder, or slag. These are 'shingled' under the hammer to express as much as possible of the involved slag and to shape the iron into a puddled bloom, which is rolled to merchant sizes in the rolls figured in fig. 4. The quality of wrought-iron is largely determined by the skill of the puddler in oxidising the impurities from the pig-iron without oxidising the iron itself. Wrought-iron may contain 2 per cent. of involved slag, which gives it its so-called fibrous fracture. It has already been pointed out, with reference to Swedish wrought-iron, that all wrought-iron is crystalline. But iron free from dissolved oxide of iron breaks along the slag-streaks, whilst bad iron, ruined with oxygen, snaps through the crystals themselves, and is hence treacherous.

Malleable Iron.—This product, which may be so

Fig. 4.—Rough and Finishing Rolls.

soft as to bend double, is prepared from pig-iron by a process exactly the opposite of the cementation applied to Swedish wrought-iron. The brittle pig-iron castings are embedded in iron ore and heated to a red heat. The oxygen of the iron ore (Fe_2O_3) removes the carbon from the pig-iron, and a pro-

duct as low as 0.15 per cent. of carbon may result. The ductility of this material, however, as measured by elongation percentage, is low, seldom exceeding 7 per cent. on $\frac{1}{2}$ inches. In 'black heart' malleable castings an almost decarbonised outer skin surrounds an uncarbonised interior, in which, how-

ever, the carbon has passed from combined carbon to free graphite, thus bringing about a great toughening of the product.

Steel.—It is difficult, if not impossible, accurately to define the metallurgical product called steel. Ordinary steel is essentially iron containing combined carbon, in amounts varying from 0.1 to 2 per cent., which has been reduced to the liquid condition and cast into ingots for the production of a metal capable of being forged or hammered. This definition includes nearly all the plain carbon steels produced in Bessemer and open-hearth furnaces (and consequently by far the greater part of the world's output of steel), but it excludes, on the one hand, blister and shear steels, and on the other the important and increasing number of alloy steels containing a variety of metallic elements besides iron. A characteristic property of steel is the hardness which it acquires after heating it to redness and then cooling suddenly by plunging it into cold water. Definitions of steel frequently include this property as a fundamental part of them, though the property is not exhibited by very mild steel, which may contain as little carbon as wrought-iron, or even less. Mild steel, suitable for ship plates, contains about 0.2 per cent. of carbon, and will stretch under a tensile stress so as to show an elongation of about 50 per cent. on

Fig. 5.

a 2-inch test-piece before fracturing, when the load reaches about 20 tons per square inch. On the other hand, a tool steel suitable for a chisel and containing about 1 per cent. of carbon, requires a load of about 60 tons per square inch to effect fracture, whilst the elongation falls to about 5 per cent. Moreover, whilst the former is not sensibly hardened by quenching from a red heat, the latter becomes hard enough to scratch glass. Increase of carbon content produces, therefore, increase of tenacity and hardness, and decrease of ductility. Within limits, this statement is correct, and a specific carbon content represents and implies in practice a steel suitable for a particular purpose; a limit to the amount of carbon is imposed by the brittleness associated with very hard material.

Plain carbon steels may be roughly divided into structural steels and tool steels. English Bessemer steels are mostly of the former class, and include ship plates and sheets (0.2), axles (0.25), tires (0.30), rails (0.30 to 0.40), and springs (0.50), the figures in brackets showing carbon percentages. Open-hearth steels also belong for the most part to the same class, though a considerable amount of tool steel is now made in acid furnaces. Crucible and shear steels are almost exclusively made up into tools such as chisels (0.90-1.0), large files and drills (1.10), turning tools (1.20), saw files (1.40), razors (1.50).

Alloy steels are produced in the crucible, the open-hearth, and the electric furnace, the last-named being adaptable to almost any class of material.

Blister-steel.—This is made from Swedish wrought-iron, 3 inches by $\frac{5}{8}$ inch bars, by cementation in charcoal. The cementation furnace (fig. 5) contains two firestone chests, *cc*, capable of containing from twelve to forty-eight tons of bar-iron each. The nearly pure Swedish iron is packed in charcoal, and the top of each chest is made air-tight by turning over it a 'wheelswarf' arch. Wheelswarf is obtained from grinding-wheels, and consists of a mush of sandstone with steel particles and oxide of iron intermixed. The expansion of the steel particles into oxide at a red heat counteracts contraction cracks in the swarf, and so maintains an air-tight chest. The chests and their contents are then raised to a yellow heat (about 1100° C.) by means of coal or producer gas. The object of cementation is to introduce into the iron, as it were, in the 'dry way,' from about 0.6 to 2.0 per cent. of carbon. The latter figure marks the limit of carbonisation possible by the cementation process. The firing lasts from about eight to eleven days, according to the carbon content required, and the cooling-down period occupies an additional twelve or fourteen days. When cold the bars are unpacked, and it is found that they present on their surfaces a series of blisters, irregular in arrangement and dimensions. The bars are now so brittle that they are easily broken by blows from a hand-hammer. They are sorted and numbered by fracture. The numbers range from No. 2 to No. 6, the carbon rising with the numbers from 0.5 in the No. 2 bar to nearly 2 per cent. in the No. 6 bar. No. 2 bar shows 'sap'—that is, an inner rectangular area of virtually uncarbonised iron. The outer layer of this bar, however, contains nearly 1 per cent. of carbon, and a median area about 0.5 per cent. In Nos. 3 and 4 bars the carbon ranges from 0.9 per cent. carbon in the centre to 1.5 per cent. on the outside; whilst Nos. 5 and 6 bars are fairly even throughout, containing about 1.75 per cent. of carbon.

The blisters on cemented bars are important as evidence that the basis metal was wrought-iron. These blisters are really small bubbles of plastic steel blown by the gas CO. When the diffusing carbon reaches the highly basic ferrous silicate slag involved in the iron bars, it reduces the slag to metallic iron, alloyed with silicon, with an evolution of carbonic oxide gas. Bars of blister-steel, after hammering and rolling to any desired section, are sometimes used direct without applying the intermediate operations of 'shearing' or melting, to be presently considered. As the basis metal of the highest quality of cutting steel Swedish bar-iron is costly, and hence fraudulent practices obtain in this connection to a considerable extent. The cheapest kind of mild basic steel is converted by the cementation process, and sold as blister-steel, or, to be exact, as 'Irish blister-steel,' a very suitable name since the bars are quite devoid of blisters.

Shear-steel.—This steel shares with blister-steel the honour of being the purest steel the world produces. Its name is due to the fact that about two hundred years ago cloth-cutters insisted on their shears being made of this material, and to this day its brand is a rude representation of a pair of shears. This steel is manufactured from blistered-steel in the following manner: The 3 inches by $\frac{5}{8}$ inch cemented bars are heated and hammered to a smaller size, so as to flatten down the blisters, and to toughen the very brittle bars so that they may withstand the severe operation of welding. About seven of the 'plated' bars are 'piled,' coated with a flux to prevent, as far as possible, surface decarbonisation, and welded at a bright-yellow heat. The welded mass is drawn down under the hammer to, say, $1\frac{1}{2}$ inch square, and is then rolled to any desired size—say into

'strings' for table knife-blades 1 inch by $\frac{1}{8}$ th inch. This is 'single shear-steel.' Double shear-steel is made by nicking and bending back upon itself the $\frac{1}{2}$ -inch square 'faggot' of single shear-steel, and then drawing the doubled material down again to, say, $\frac{1}{2}$ inch square before rolling to size. Single shear-steel is branded with a figure representing one pair of shears. Double shear-steel is branded with two pairs of shears. The chemical composition of shear-steel is that of Swedish bar-iron, plus carbon, from about 0.7 to 1.3 per cent.

Crucible-steel.—This world-famous steel was invented at Sheffield in 1740 by Benjamin Huntsman. He conceived the idea of melting blister-bar in a clay 'pot,' and casting the fluid mass into an ingot. The fuel used is, as nearly as possible, sulphur-free coke of high calorific intensity. Two pots are placed in each 'hole,' which has a separate flue connected with a stack. The combustion is obtained by natural draught, the stack being about 35 feet high. A temperature of about 1600° C. is thus obtained, so that iron, containing as little as 0.05 per cent. of carbon, can be melted. The broken blister-bar with, say, 15 per cent. of scrap crucible-steel is charged into the pot and 'clear melted.' If poured at this stage the steel is commercially worthless, being riddled with gas cavities called 'blow-holes,' which contain hydrogen, carbonic oxide, and nitrogen gases. The steel requires 'killing' before pouring into an ingot. Killing is a thermo-chemical process. The temperature is raised to a maximum, and some form of metallic manganese is added. This manganese acts as a carrier of silicon from the walls of the crucible into the steel. The silicon, in some way not known, either eliminates or causes to remain absorbed the gases which would otherwise be evolved during solidification, and so ruin the steel. A mere trace of metallic aluminium (0.005 per cent.) has a similar effect. The ingots are then hammered and rolled to size. Crucible-steel is less pure than blister or shear steel. It generally contains about 0.3 per cent. of manganese, about 0.15 per cent. of silicon, and about 0.025 per cent. of sulphur from the melting coke. The SO_2 gas evolved from the coke readily passes through the walls of the crucible, although these are $\frac{3}{4}$ inch thick.

Bessemer Steel.—The Bessemer process consists essentially in the removal of carbon, silicon, and

Fig. 6.

the 'blow,' the pig-iron used must contain only small amounts of these elements. In the English method equal parts of Nos. 1, 2, 3 Bessemer pigs are melted in a cupola by means of coke, and are run into the Bessemer vessel (fig. 6),

which is turned down so that the molten pig has the level *fe*. The air-blast, at a pressure of about 25 lb. per square inch, is turned on and the vessel turned up. The pressure from the blast-box (*cccc*) prevents the molten charge from descending through the fire-clay tuyères (*dddd*). The 'mixed numbers' charged into the cupola have the following average composition: combined carbon, 0.40; graphite, 3.6; silicon, 2.5; manganese, 0.3; sulphur, 0.05; phosphorus, 0.05. The changes in the cupola are slight—about 0.2 per cent. of silicon is oxidised, and from 0.01 to 0.02 per cent. of sulphur is absorbed from the coke. The 'blow' occupies about twenty-five minutes, and presents three stages. The first stage is quiet, as the silicon is absorbing most of the oxygen to form SiO_2 , which rises as a 'scum' to the surface of the bath. In the next stage the carbon is being more rapidly oxidised, forming CO gas, which, escaping, carries with it particles of metal and slag, producing that pyrotechnic display characteristic of the Bessemer process. The third or 'fining' stage is distinguished by a diminishing flame, which drops when the carbon has virtually disappeared. The composition of the 'blown metal' is as follows:

Combined carbon.....	0.04
Silicon.....	0.03
Manganese.....	0.02
Sulphur.....	0.07
Phosphorus.....	0.06
Iron by difference.....	99.78

This blown metal is commercially worthless, as ingots cast from it are full of blow-boles and incapable of being forged. This is due to the fact that in the 'iron by difference' figure is really included from 0.3 to 0.5 of dissolved oxygen, equivalent to about 2 per cent. of FeO , which renders the material hopelessly 'red-short.' The dissolved oxide is removed by an invention of Mushet, which consists in the addition of sufficient manganese to bring about the reaction $\text{FeO} + \text{Mn} = \text{Fe} + \text{MnO}$, the dissolved ferrous oxide being thus exchanged for an insoluble oxide of manganese, which slags out.

Early samples of Bessemer steel made in the 'sixties' contained only about 0.3 per cent. of manganese, and hence forged with difficulty. It is found necessary to add to the blown metal about 1.7 per cent. of metallic manganese, and of this about 0.7 per cent. passes into the slag.

The variation of carbon necessary in the Bessemer-Mushet process was secured by means of the alloys known as 'spiegel' and 'ferro-manganese.' 'Spiegeleisen' (German, 'looking-glass iron') contains about 4.3 per cent. of carbon and 15 per cent. of manganese. It fractures along bright faces composed of plates of the double carbide of iron and manganese—hence the somewhat fanciful German name. Ferro-manganese, which has a granular break, contains (to take two types) 5.5 per cent. of carbon and 50 per cent. of manganese, or 6.8 per cent. of carbon and 80 per cent. of manganese. These varying alloys are made so as to give the English Bessemer steel metallurgist a means of keeping his manganese constant at about 1 per cent., whilst his carbon may range from, say, 0.20 to 0.75 per cent., or, in other words, from mild axle-steel, through moderately hard rail-steel, to specially hard spring-steel. 'Spiegel,' which is added to, say, an eight-ton Bessemer heat in quantities approximating a ton, is introduced into the blown metal in a fluid form from an auxiliary cupola. 'Ferro-manganese,' of which perhaps only six hundredweights are required, is added cold.

The presence of large amounts of the acidic body, silica, makes it impossible to remove phosphorus except at temperatures too low for making structural steels. This circumstance led naturally to the introduction by Thomas and Gilchrist of furnaces

lined with a basic material, in which phosphoric irons could be successfully purified to produce good steel. The lining consists essentially of a mixture of two basic oxides, lime (CaO) and magnesia (MgO), themselves the products of the calcination of native dolomite, a mineral composed of the carbonates of calcium and magnesium ($\text{CaCO}_3\text{-MgCO}_3$). The pig-iron charged in the basic Bessemer process should contain less than 1 per cent. of silicon and under 0.1 per cent. of sulphur (which is only partially removed in the process), but may advantageously contain up to the high figure of 3 per cent. of phosphorus; with each ton of iron about 3 cwt. of lime are charged. The blow is continued as in the acid process until the flame drops, indicating the removal of carbon. At this stage phosphorus still remains, and an 'after-blow' over a period of some minutes is required to oxidise it out. No visible indication marks the progress of the oxidation, so that it is necessary to remove samples by turning the converter down and casting

at about 1500° , and steel somewhat lower, so that without the 'regenerative principle' first applied by Siemens (and to steel-making in particular by Martens) the process would be impracticable. The furnace is of the reverberatory type, and may be stationary or tilting, with any capacity from 3 to 300 tons. Fig. 7 shows a typical open-hearth furnace with the regenerators underneath. The producer gas and air pass over a chequer-work of firebricks in a gas-regenerator G and an air-regenerator A, and ignite on the hearth H. The hot products of combustion pass evenly through A_1 and G_1 , and heat up the firebricks in them before passing away by the stack. The direction of the gas and air is reversed at intervals of 20 to 30 minutes, and the cold gases reabsorb the heat from the hot chequer-work before ignition on the hearth. As in the Bessemer process, the furnace lining immediately in contact with the charge is acid or basic according to the nature of the pig-iron which makes up usually the greater part of the charge. In the acid

process the bed is sand, and as a new bed absorbs a large amount of slag, it is usual to saturate it with slag before the first charge. The slag produced is also acidic, and at finishing contains about 55 per cent. of silica. In this process it is possible to remove, if necessary, practically the whole of the carbon, silicon, and manganese from the pig-iron, but no sulphur or phosphorus; indeed, the final percentages of these elements may actually be more than in the pig-iron charged, as is invariably the case in the acid Bessemer process. This is due to loss of weight by elimination of the other

Fig. 7.—Open-hearth Furnace.

Modelled by permission on a diagram in D. Carnegie's *Liquid Steel* (Longmans).

a small ladleful of the metal into an iron chill. The texture of the surfaces of the fractured sample is a sufficient guide to the phosphoric content of the solid metal. When a close-grained fracture is obtained, the slag is run off as quickly as possible and the calculated amount of ferro-manganese added. The basic slag produced contains about 15 per cent. of P_2O_5 in the form of calcium phosphate, and thus makes an excellent fertiliser for crops.

Open-hearth Steels.—The open-hearth process of steel-making gradually superseded the Bessemer process, and has now almost ousted it, principally on account of the fact that in its final stages it is under complete control, and the finished product is more reliable. The fuel used is 'producer gas,' having as a typical composition 25 per cent. by volume of carbon monoxide, 5 of carbon dioxide, 10 of hydrogen, 5 of methane (CH_4), and the remainder nitrogen. Such a gaseous mixture when cold and burnt in cold air would develop a temperature of approximately 1000°C ., but if both gas and air be pre-heated to $500^\circ\text{--}600^\circ$, temperatures of $1600^\circ\text{--}1700^\circ$ are attained. Pure iron melts

elements and, to a slight extent, to absorption of sulphur from the furnace gases. It is therefore necessary to use high-grade irons and the purest iron ore for refining. In the basic process the working-bed is of hard-burnt dolomite, finely ground and mixed with boiled tar. The slag is a basic one, containing about 44 per cent. of lime at finishing. In this process the carbon, silicon, manganese, phosphorus, and much of the sulphur are removed, and it is thus possible to make first-class steel from common foundry pig-iron containing up to 2 per cent. of phosphorus.

The conduct of both processes is very much the same. The furnace is charged either with molten pig-iron direct from a blast-furnace or a 'mixer,' or with a mixture of cold pig-iron, scrap, and suitable flux. In the latter case much of the impurities in the iron is oxidised out during the melting process. The refining period now commences. Oxide of iron, either in the form of iron ore or mill scale, is added in small amounts at a time, with more flux if necessary. The oxygen of the iron ore combines with the carbon, silicon, manganese, and phosphorus, forming CO , SiO_2 , MnO ,

and P_2O_5 respectively. The carbon monoxide, as it rises through the slag, creates an appearance of boiling; it then burns to CO_2 , and passes as such into the waste gases. The SiO_2 and MnO remain in the slag in the acid process, but the phosphorus is reduced again at the high temperature which obtains and remains in the metal along with the sulphur. In the basic process the P_2O_5 is also eliminated in the slag, which consists principally of phosphates and silicates of lime, iron, and manganese, whilst acid slag consists principally of silicate of iron with smaller amounts of silicates of lime and manganese. Samples of the metal are taken at frequent intervals and analysed. When the carbon is down to the desired amount, and the spoon sample quite solid and free from blow-holes, the bath is freed from dissolved oxide by the

addition of the 'finishings.' These consist of ferro-manganese, spiegel, ferro-silicon, carbon in the form of anthracite, &c., in sufficient quantity to yield a steel of specified analysis. In the acid process these are added to the bath before tapping, but in the basic method it is usual to add them to the ladle. About 1 per cent. of metallic manganese is added in the form of one of its alloys, and of this about 0.4 per cent. passes into the slag, leaving 0.6 per cent. in the metal, whilst the ferro-silicon adds about 0.15 per cent. of silicon in the 'killing' process. A typical heat of acid Siemens steel for structural purposes is cast in, say, 10-inch square ingots, weighing about three-quarters of a ton each. These ingots may

be hammered, or hammered and rolled (after being thoroughly re-heated in the 'soaking-pit'), into, say, 1-inch round steel for bolts. The composition may be combined carbon 0.30, silicon 0.10, manganese 0.5-0.6, and sulphur and phosphorus about 0.05 per cent. each. Such steel shows an elastic limit of 18 tons per square inch, a breaking stress of about 35 tons per square inch, an elongation of about 26 per cent. on 2 inches, and a reduction of area of about 60 per cent.

Electric Furnace Steel.—Practically all the electric furnaces used for the manufacture of iron and steel in Britain are of the arc type; moreover, furnaces of the indirect arc class, such as the Héroult, and those of the combined arc and resistance type, such as the Electro-Metals and Greaves-Etchells furnaces, greatly outnumber all others. Fig. 8 shows a modern Greaves-Etchells furnace. In Sweden, where the cost of power is relatively low, the induction furnace is favoured.

Owing to the high cost of electrical energy, cheap scrap is in most cases the essential con-

stituent of an electric furnace charge. Heavy turnings from acid and basic Siemens steels make an ideal material, though usually scrap-ingots and crop-ends from the forge and mill are available also. No charge should consist entirely of heavy scrap, otherwise breakage of the electrodes is liable to occur. A charge usually contains between 0.04 and 0.08 per cent. each of sulphur and phosphorus, and as finished electric steels are of very high quality, these elements must be reduced considerably, usually 0.025 per cent. being regarded as an absolute maximum. Basic lined furnaces are therefore almost a necessity; crushed burnt dolomite mixed with a small amount of basic slag is the material generally used. This is mixed with boiling tar, and rammed into position around wooden templates; it is afterwards effectively burnt

Fig. 8.—Greaves-Etchells Electric Furnace.

in by electrical means. Melting of the charge is carried out under oxidising conditions so as to eliminate phosphorus, and for this purpose iron ore, fluorspar (or sand), and lime are added as soon as a bath is obtained. Oxidation of the carbon, silicon, and manganese takes place during the melting-down period, and analysis of the bath when the phosphorus is down to the required amount shows C less than 0.12, Mn 0.1-0.3 per cent., and Si traces. The manganese content depends to a great extent on the method of working; American steel makers use a manganiferous ore for the oxidation, whilst certain makers in this country add ferro-manganese with the slag-making materials. The manganese prevents over-oxidation of the metal, and also partially removes sulphur by forming MnS . As the second stage of the process is of a reducing kind, it is necessary to remove the black oxidising slag containing phosphates, otherwise the latter would be reduced, and phosphorus would re-enter the metal. The furnace is therefore tilted, most of the slag run off, and the last portions

completely removed by skimming with rakes. After this operation the necessary carburisation of the bath is brought about by adding anthracite coal to the slag-free surface, the metal and coal being brought into intimate contact by stirring with long wooden poles. The final stage of the process consists of the attainment of reducing conditions for the removal of sulphur and oxides of iron and manganese. For this purpose a new slag, made by adding lime, fluorspar, crushed coal or coke, and ferro-silicon, is added to the bath. These quickly melt, and the slag gradually changes from black to white as the following reactions proceed: $\text{FeO} + \text{C} = \text{Fe} + \text{CO}$ and $2\text{MnO} + \text{Si} = \text{SiO}_2 + 2\text{Mn}$. A 'good' slag spontaneously disrupts on cooling, forming a white powder which, on quenching, emits the characteristic odour of acetylene. The latter is the result of the formation of calcium carbide, CaC_2 , in the slag, and is an indication that desulphurisation is proceeding. The sulphur is removed as calcium sulphide, CaS , which is soluble in basic slags but insoluble in molten steel. In order that CaS may be formed it is necessary that the slag be free from metallic oxides, since otherwise sulphur would be returned to the metal as soluble FeS produced by the reaction $\text{CaS} + \text{FeO} = \text{CaO} + \text{FeS}$. The presence therefore of CaC_2 in the slag indicates freedom from metallic oxides and, what is more important, freedom of the metal from them, if time is allowed for equilibrium conditions to be established. The flexibility of the electric process of steel-making is remarkable; high-carbon tool steels, low-carbon case-hardening steels, high-speed steel, and all classes of alloy steels are made to a large extent in the electric furnace. A few acid-lined furnaces are in use chiefly for the manufacture of steel castings.

Case-hardening Steels.—Case-hardening is the term applied to the operation of imparting a hard skin or surface to mild steels whilst the interior is unaffected, and thus retains its original toughness. In other words, it is a process of partial cementation. The steel articles are embedded in a carbonising mixture in an iron box and heated for a length of time, 12 to 48 hours or more, dependent upon the thickness of case required, after which they are usually quenched in water. Toothed wheels, cams, axles, parts of valve-gearing, &c., are generally case-hardened. It is also possible to secure the efficient surface-hardening of large pieces and of complicated forms, and thereby run less risk of cracking by hardening than when such materials are of high-carbon steel throughout the entire mass. The carbonising material is not usually charcoal alone; a good mixture is made from 3 parts charcoal and 2 parts barium carbonate. Many mixtures contain nitrogenous material, such bodies as potassium ferro-cyanide, leather, parings from horns and hoofs being found in the various mixtures supplied by the trade. It is claimed that the cyanogen gas generated by the decomposition of these bodies is the active reagent in the process; it is, however, certain that the introduction of carbon is primarily due to carbon monoxide. As the materials treated are, or should be, free from slag, the case-hardened products are free from the blisters which characterise cemented bar-iron.

Steel-castings.—So far, in connection with crucible Bessemer and Siemens steels, the properties of the forged ingots have alone been considered. In steel-castings we have forms too complicated to forge; hence such articles are cast in more or less mild steel, and to endow them with the necessary toughness the operation known as flame-annealing is substituted for that of forging. A mild-steel casting 'as cast' in a mould of refractory material is very brittle. It may contain, say, 0.35 per cent. of combined carbon, 0.3 per cent. of silicon, 1 per cent.

of manganese, and under 0.1 per cent. each of sulphur and phosphorus. Its maximum stress will be about 30 tons per square inch, and its ductility as measured by elongation and reduction of area in the static test will be very small, say 5 per cent. each. After annealing the maximum stress will be, say, 32 tons per square inch, and the elongation and reduction of area will have risen to about 30 per cent. each. Before annealing, a bar, as cast, 1 inch square will break after bending through an angle of, say, 10° . After annealing, the bar will bend over 100° before fracturing. Annealing is not a chemical but a recrystallising operation. The castings are heated up to about 1000°C. , and are allowed to cool slowly during a period of about three days. Thus the acutely developed octahedral crystallisation of the ferrite and pearlite of the mass is broken up into rounded masses. A terrestrial steel-casting before annealing has the same structure as a celestial steel-casting—i.e. as a meteorite.

Alloy Steels.—Of the four elements associated with carbon in all plain carbon steels manganese only is present in quantity, and seldom in amounts exceeding 1 per cent. When other elements, such as nickel, chromium, tungsten, &c., are added singly or in combinations of two or more, the so-called 'alloy' steels are produced. The term also includes special high silicon and high manganese steels. Alloy steels possess mechanical properties differing remarkably from those of plain carbon steels of the same carbon content, and almost any required degree of tenacity, ductility, or other mechanical property may be secured by a combination of suitable chemical composition with correct heat-treatment. The carbon percentage of the great majority of modern alloy steels rarely exceeds 0.45, except in the case of high-speed tools. In the following paragraphs the effect of the alloying elements taken singly is first described, and a brief consideration of the most important alloy steels containing two or more elements follows.

Tungsten is used in the manufacture of steels for taps, dies, drills, and turning tools. Comparatively small amounts, up to 2 per cent., impart an exceedingly fine grain to steel, which is just as hard and not so brittle after hardening as plain carbon steel. Moreover, it is less liable to decarburisation during heating operations, and the hardening temperature is not unduly raised by the addition of amounts of tungsten not exceeding the above figure. Tungsten steel for permanent magnets contains about 6 per cent. of that element, with a carbon content about 0.65. **Chromium** is added to high carbon steels in small amounts, essentially to prevent decomposition of the iron carbide in heating operations; such decomposition results in the liberation of free carbon (graphite), softening of the steel, and therefore its ruination. Razor steel frequently contains up to 0.5 per cent. of chromium. Ball-bearing and ball-race steels are greatly improved by as little as 0.25 per cent., the toughness being increased without any sacrifice of hardness. The highest grades of ball steel contain from 1.0 to 1.5 per cent. of chromium, and often also from 0.25 to 0.5 of tungsten; they are very hard indeed, and possess a very high resistance to crushing stresses. 'Stainless' steel for cutlery usually contains from 12 to 14 per cent. of chromium, with a carbon content not exceeding 0.5 per cent. The combination of stainlessness and hardness depends upon the complete solution of the chromium carbide formed, and the higher the carbon content the more difficult it is to obtain complete solution, owing to the very slow diffusion on heating. Moreover, the higher the carbon the higher must the chromium percentage be, in order to ensure resistance to corrosion. Steels of the stainless type have found extensive use for valves in internal

combustion engines, and although the non-corrodible properties are valuable, probably the most important property of such steels is that of retaining their tensile strength to a remarkable extent at high temperatures. The tensile strength required necessitates a higher carbon content than that of steel for cutlery. *Silicon*.—The most important of the silicon steels contains 1.25 to 1.75 per cent. of the element, with carbon 0.5 and manganese 0.6. It is largely used for making springs for automobiles and air-craft. After suitable heat-treatment it has a tensile strength of about 100 tons per square inch, giving an elongation of 10 per cent. on a 2-inch piece, and a reduction of area of 25 to 30 per cent. A 3 to 4 per cent. silicon steel is used for the manufacture of a 'stainless' valve, and an almost carbonless steel with about the same amount of silicon is used for parts of electrical machinery where a low hysteresis is required. The effect of the silicon is to decompose the small amount of iron carbide, giving a material which is equivalent to pure iron for the purpose required. *Manganese*.—The effect of adding manganese in amounts greater than those used in Bessemer practice (about 1 per cent.) is remarkable. From 1.5 and up to about 6 per cent. makes the metal brittle, but from the latter point upwards, not only is increasing hardness conferred, but also the peculiar property of increased toughness after quenching from a red heat. Hadfield's manganese steel contains from 12 to 15 per cent., with carbon 1.0 to 1.3. It is quenched in water from about 1000° C., becoming hard, tough, and practically non-magnetic. It is distinguished from most other steels by becoming magnetic and progressively harder when subjected to tempering, though the original tough and non-magnetic condition can be restored by heating again up to 950° C. and quenching. Manganese steel cannot be machined, but it may be punched and sheared; it is forged first, then water-toughened, and finished by grinding. *Nickel* is largely used for the manufacture of a 3 per cent. dead mild steel (carbon 0.1) for case-hardening, the required hardness of surface being accompanied by remarkable toughness and resistance to shock in the main body of the material. Specially high nickel steel, 25 to 30 per cent., is used for turbine blades and gas-engine valves, being exceedingly tough and highly resistant to the corroding action of sea-water. An approximate composition is: carbon 0.5, manganese 1.25, chromium 0.5, and nickel 30, other elements normal. The alloy steel known as 'Invar' contains 36 per cent. of nickel. Its coefficient of thermal expansion being nearly zero, no appreciable alteration in size takes place by ordinary changes of atmospheric temperature. *Cobalt*, added to steel containing about 0.9 per cent. of carbon, improves the magnetic properties to a remarkable extent, and high-percentage cobalt steels are far superior to the ordinary tungsten magnet steels. They are extremely hard and somewhat brittle, and thus require great care in forging. Chromium is added to them, with the effect of preventing graphitisation during hot working. Typical analyses of two magnet steels are: (1) carbon 0.9, manganese 0.4, chromium 5.0, cobalt 5.0; (2) carbon 1.0, manganese 0.4, chromium 8.0, cobalt 10.0 to 12.0. Cobalt-chromium steel entirely free from tungsten is also made up into high-speed turning tools; it possesses the property of hardening by allowing to cool in air. *Vanadium* is a most valuable metal for ensuring soundness in steel ingots, removing oxides from the molten metal better perhaps than manganese. It is added in amounts not exceeding 0.2 per cent. to ordinary tool steels as well as to nickel-chrome steels. Larger amounts are used in the manufacture of high-speed steels (see below).

Tungsten-chromium: Self-hardening and High-speed Steels.—Mushet first discovered that steels containing much tungsten were extremely hard after cooling from the forging temperature without quenching, and they became known as self-hard steels. At first no chromium was introduced, but subsequently as much as 2 per cent. was added, the carbon and manganese contents also exceeding 1 per cent. each. Self-hard steels quickly revolutionised tool-steel practice, as they were found to stand up quite well when both increased cutting speeds and resulting high temperatures obtained. The composition of modern self-hard steels varies very much, carbon ranging from 1.5 to 2.25, manganese up to 2 per cent. or more, chromium from 0.3 to 10 times that amount, and tungsten from 5 to 12.

Self-hard steel may be regarded as the forerunner of the modern high-speed steels. The latter are to a great extent self-hardening, but it was found that by decreasing the carbon and increasing the tungsten content a hardening operation resulted in the production of a material possessing extraordinary cutting qualities at very high speeds. The hardening temperature is about 1350° C., which would completely ruin plain carbon steel. After quenching, the hardness of high-speed steel can be increased further by heating to a temperature of 650-700° C., which induces what is termed secondary hardness. With the exception of carbon, tungsten is the dominating constituent of high-speed steel both as regards quality and price. In general the steels fall into one or other of two classes which contain 14 and 18 per cent. of tungsten respectively. The carbon of the former varies from 0.65 to 0.75, and of the latter from 0.55 to 0.65, from which it will be seen that the higher carbon content is associated with the lower tungsten value, and *vice versa*. The method of hardening these steels is a point of some importance—e.g., a 14 per cent. tungsten steel containing more than 0.70 per cent. of carbon would probably crack if quenched in water; hence oil-quenching or cooling in a blast of air is the usual practice in hardening steels containing more than 0.65 per cent. The effect of chromium is to increase the secondary hardness and lower the hardening temperature, but too large an amount creates difficulties in forging and rolling; the usual amount in modern high-speed steels lies between 3 and 4 per cent. Vanadium is added by some makers in amounts varying from 0.25 to nearly 2 per cent., and it is claimed that the cutting and air-hardening properties of the material are thereby increased. Molybdenum is also used to a limited extent in amounts varying from 1 to 2 per cent. Manganese and silicon in high-speed steels rarely exceed 0.3 per cent.

Nickel-Chrome Steels.—The combination of nickel and chromium in steel-making has been made use of for special purposes for a comparatively long time. The protective armour of battleships, alike with the shells for piercing it, may be cited as cases in point. Of perhaps greater importance at the present time is the use of nickel-chrome steels in the automobile, air-craft, and general engineering trades. The chief cause of this is the fact that the degree of strength required, be it tenacity, hardness, or resistance to fatigue stresses, can be obtained from them, and by the use of relatively small sections.

Nickel-chrome steels resemble low nickel steels free from chromium in general properties and uses, but possess greater hardness and strength, though they require greater care in working. Their heat-treatment admits of wider variation, giving an enormous range of mechanical tests which enable them to be used for a large number of parts requiring

very different properties. The carbon content is low in all cases, ranging from 0.15 in the mildest to not more than 0.4 per cent. in the hardest, but the chromium and nickel show greater variations. Some of them are air-hardening steels, a notable sample being one with a carbon content of 0.35, nickel 4.0, chromium 1.5 per cent., which requires a tensile stress of 100 to 120 tons per square inch in order to rupture it. A curious phenomenon of these steels is the brittleness which can be induced in them, and is therefore carefully avoided by tempering at about 300° to 350° C. Appended are three typical engineers' specifications for nickel-chrome steels.

(1) Carbon 0.25 to 0.35, nickel 1.25 to 1.75, chromium 0.75 to 1.25. Oil-hardened from 850° C. and tempered at 600° must show a breaking stress not less than 45 tons per square inch, elongation 15 per cent., and reduction of area 50 per cent.

(2) Carbon 0.20 to 0.30, nickel 2.75 to 3.5, chromium 0.45 to 0.75. Oil-hardened from 820° C. and tempered at 600° must show a breaking stress of 45 tons per square inch, elongation 15 per cent., and reduction 50 per cent.

(3) Carbon 0.28 to 0.36, nickel 3.5 to 4.5, chromium 1.25 to 1.75. Air-hardened from 820° C. must show a stress of at least 100 tons per square inch, reduction 5 per cent., and elongation 13 per cent.

For analysis of iron and steel, see *Steel Works Analysis*, by Arnold and Ibbotson; *General Steel and Iron Metallurgy*, by Harbord and Hall; *General Foundry Practice*, by McWilliam and Longmuir; *Malleable Cast Iron*, by Hatfield; *Metallurgy of Iron*, by Turner.

IRON IN ITS PHYSIOLOGICAL AND THERAPEUTIC RELATIONS.—Iron is an essential constituent of the colouring matter of the blood-corpuscles of all vertebrate animals; and, according to the best authorities, one part by weight of iron is found in 230 parts of blood-corpuscles, and the total quantity of this metal in the blood of a man weighing 140 pounds is about 38 grains. It is the presence of iron in the blood that communicates to the ashes of blood their reddish-brown colour, the iron being found in them as the peroxide. The ashes of hair, of birds' feathers, of the contents of eggs, of gastric juice, of milk, and of most animal fluids contain traces of iron.

Iron in the blood is combined in a protein substance, hæmoglobin, which readily takes up oxygen; it probably exists as protoxide in the venous blood and peroxide in arterial blood. It is introduced into the system with the food and drink, and any excess beyond what is required is discharged with the excrements. It is thus a food rather than a medicine; but when an insufficient quantity is contained in the nutriment, or when from any cause the absorption of the iron contained in the food is interfered with, chalybeate medicines become necessary in addition. The iron that is set free within the system by the constant disintegration of blood-corpuscles is carried out of the system partly by the urine, partly by the bile, but is to a large extent re-utilised in new blood-formation, in the growth of hair, &c. The exact part which the iron plays in the body is uncertain; but it is most probable that the power which the blood-corpuscles possess as oxygen-carriers is mainly due to the presence of iron.

In most forms of Anæmia (q.v.), especially Chlorosis (q.v.), the iron compounds are of incomparably more service than any other remedies. In amenorrhœa, in certain painful nervous affections, and in many conditions of debility the salts of iron are of special service. They are contra-indicated in plethora, and in conditions that are accompanied by fever. The forms in which iron may be prescribed are very numerous, and vary considerably in their utility, according to the

readiness with which they get taken up into the blood. Amongst the most generally used ferruginous medicines may be mentioned reduced iron, the tincture of the perchloride, the saccharated carbonate, Bland's pills (containing the carbonate), the sulphate, the tartrate, several citrates (especially the citrate of iron and quinine), &c. A course of chalybeate waters (see MINERAL WATERS) may often be prescribed with great advantage when the patient cannot bear the administration of iron in its ordinary medicinal form.

Iron Age, an archaeological term indicating the condition as to civilisation and culture of a people using iron as the material for their cutting tools and weapons. It is the last of the prehistoric stages of progress represented by the series of the three ages of Stone, Bronze, and Iron. But it has to be remembered that this sequence is not necessarily true of every part of the earth's surface, for there are areas, such as the islands of the South Pacific, the interior of Africa, and parts of North and South America, where peoples have passed directly from the use of stone to the use of iron without the intervention of an age of bronze. In Europe the iron age may be defined as including the last stages of the prehistoric and the first of the protohistoric periods. As the knowledge of iron seems to have travelled over Europe from the south northwards, the commencement of the iron age was very much earlier in the southern than in the northern countries. Some think that the use of iron was discovered or invented in Africa. Iron is named in Egyptian records as early as 3400 B.C., and rare finds show it to have been in use as a precious metal from pre-dynastic times till the 18th Dynasty. In Crete also iron was used for jewellery before the iron age succeeded the late Minoan stage of culture, which still cherished bronze weapons. The age of iron here begins about 1200 B.C. As early apparently iron was known to the Etruscans. Greece, as represented in the Homeric poems, was then in the transition period from bronze to iron, while Scandinavia was only entering her iron age about the time of the Christian era. The transition from bronze to iron in central Europe is exemplified in the great cemetery, discovered in 1846, of Hallstatt, near Gmunden, where the forms of the implements and weapons of the later part of the bronze age are imitated in iron. In the Swiss or La Tène group of implements and weapons the forms are new and the transition complete. The Gauls seem to have used iron to some extent as early as the 7th century B.C., and most parts of northern Europe had learnt its value before the Roman invasions. In Britain the earlier Celts were still in their bronze age; the later Celts used iron to great purpose. They made their weapons of it, and used it for the tires of their chariot wheels, as we learn from the contents of their graves. They also developed the system of Celtic ornament, which was such a feature in the decoration of their metal work for some centuries before and after the Christian era. The early iron age forms of Scandinavia show no traces of Roman influence, though these become abundant towards the middle of the period. The duration of the iron age is variously estimated according as its commencement is placed nearer to or farther from the opening years of the Christian era; but it is agreed on all hands that the last division of the iron age of Scandinavia, or the Viking Period, is to be taken as from 700 to 1000 A.D., when Paganism in those lands was superseded by Christianity. The iron age in Europe is characterised by forms of implements, weapons, personal ornaments, and pottery, and also by systems of decorative design, which are altogether different from those of the

preceding age of bronze. The implements and weapons are no longer cast but hammered into shape, and as a necessary consequence the stereotyped forms of their predecessors in bronze are gradually departed from, and the system of decoration, which in the bronze age consisted chiefly of a repetition of rectilinear patterns, gives place to a system of curvilinear and flowing designs. But the principal feature that distinguishes the iron age from the preceding ages is the introduction of alphabetic characters, and the consequent development of written language which laid the foundations of literature and historic record.

N. FRIED, 'Iron in Antiquity' in *Carnegie Scholarship Memoirs*, vol. xii. (1923); and books named at ARCHEOLOGY.

Iron Bark Tree, a name given in Australia to certain species of Eucalyptus (q.v.), and particularly *E. resinifera*, on account of the extreme hardness of the bark.

Ironclads, a term first applied to wooden ships of war strengthened by a complete covering of iron armour-plates, and employed loosely even for iron ships with armour of steel. See NAVY, SHIPBUILDING.

Iron Cross, a Prussian order for distinguished services in war, instituted in 1813. The cross was of iron, plain and devoid of intrinsic value, that it might the more fitly commemorate an iron time of trial and effort. It was revived in 1870 on the eve of the war with France. In the Great War it was bestowed almost indiscriminately, and so lost much in value. -See ORDERS.

Iron Crown. See CROWN.

Iron Gates. See DANUBE.

Iron Mask, THE MAN WITH THE, a famous and mysterious prisoner so called, confined in the Bastille and other prisons in the reign of Louis XIV., whose story has long had a romantic interest for the readers of history. The first notice of him was given in *Mémoires Secrets pour servir à l'Histoire de Perse* (Amst. 1745-46), according to which he was the Duke of Vermandois, a natural son of Louis XIV. and of Mlle de la Vallière. Mouhy's romance, *L'Homme au Masque de Fer*, immediately followed, and was prohibited. The first authentic information comes from the Jesuit Griffet, confessor in the Bastille, who proved that in 1698 Saint-Mars brought a prisoner whose name was not mentioned, and whose face was always concealed by a mask of black velvet. His burial in 1703 is registered under the name of Marchiali. Voltaire, who wrote several accounts of the matter, professed to know more than he told. The editor of the *Dictionnaire Philosophique* suggested a son of Anne of Austria and the Duke of Buckingham; and the Abbé Soullavie, a twin-brother of Louis XIV. When the Bastille fell the prisoner's room was eagerly searched, and also the prison register; but all inquiry was vain. D'Heiss (1770), Dutens, Roux-Fazillac (1800), Delort (1825), and Topin (1869) argued that the Iron Mask was Count Matthioli, a minister of the Duke of Mantua, who had pledged himself to Louis XIV. to urge his master the duke to deliver up to the French the fortress of Casale, which gave access to the whole of Lombardy. Though largely bribed to maintain the French interests, he began to betray them; and Louis XIV. contrived to have Matthioli lured to the French frontier, secretly arrested in 1679,

and conveyed to the fortress of Pignerol. This was the accepted view till Jung, in *La Vérité sur le Masque de Fer* (1873), argued that Matthioli or Mathioli could not have been the mysterious prisoner. This Italian adventurer was sent to Pignerol six years after the Mask entered that fortress. He was left behind in Pignerol when Saint-Mars removed the Mask to the Bay of Cannes, and his death there was never kept secret. Matthioli could not speak French; but the man in the mask spoke French with a foreign accent. Jung's hypothesis was that the Mask was the unknown head of a widespread and formidable conspiracy, working in secret for the assassination of Louis XIV. and of some of his ablest ministers—a soldier of fortune, M. de Marchiel, related to several families in Lorraine. Seized by Louvois's orders at the ford of Péronne in March 1673, he was first forwarded to the Bastille. There Louvois saw him, and sent him to Pignerol and to the care of Saint-Mars. From that hour the jailer never parted from his strange prisoner. De Marchiel went with him to Exilles (1687), and to Ste Marguerite, and died in the Bastille, 19th November 1703; and the funeral of 'M. de Marchieli,' entered in the register of the parish of St Paul, cost forty francs. In the *Valet's Tragedy* (1903) Mr Andrew Lang contended for Eustache Danger, valet to Roux de Marsilly, a Huguenot intriguer, but supposed to be a son of Oliver Cromwell. He is identified by Monsignor Barnes, in *The Man of the Mask* (1908), as James de la Cloche, the eldest of the many illegitimate sons of Charles II. But nothing has been proved; indeed, little real proof has been led to show that he was one or any of the persons about whom so much has been written.

See T. HOPKINS, *The Man with the Iron Mask* (1901); Lord Acton, *Lectures on Modern History* (1906); L. MATTÉ, *Crimes et procès politiques* (1910).

Ironsides, a regiment of horse raised by Cromwell (q.v.). The name was given first to Cromwell himself (as it had been to Edmund Ironside), and was later extended to all Cromwell's troops and even Puritan soldiers generally.

Ironton, a city of Ohio, on the Ohio River, 142 miles above Cincinnati, the chief business centre of an important iron region; pop. 14,000.

Ironwood, a name bestowed in different countries on the timber of different trees, on account of its great hardness and heaviness.—*Metrosideros vera* belongs to the natural order Myrtaceæ, and is a native of Java and other eastern islands. Its wood is much valued by the Chinese and Japanese for making rudders, anchors, &c., and is imported into Britain in small quantities under the name of Ironwood. The bark is used in Japan as a remedy for diarrhoea and mucous discharges.—*Mesua ferrea*, a tree of the natural order Guttiferæ, is a native of the East Indies, and is planted near Buddhist temples for the sake of its fragrant flowers, with which the images of Buddha are decorated.—The wood of *Vepres lanceolata*, of the order Rutaceæ, is called White Ironwood at the Cape of Good Hope. It is very hard and tough, and is chiefly used for axles, ploughs, and other agricultural implements.—The wood of *Olea laurifolia*, a species of olive, is called Black Ironwood in the same country, and is used for the same purposes and for furniture.—*O. capensis* is the Ironwood of the Dutch settlers at the Cape, and its wood has similar properties and uses.—*Stadmannia oppositifolia* (natural order Sapindaceæ) is the Ironwood of the islands of Bourbon and Ambouyna. The wood is red in colour, very heavy, knotty, and difficult to work; it is used chiefly for making stakes and poles.—*Siderocaylon inerme* (order Sapotaceæ), belonging to the Cape of Good Hope, is named Ironwood and also *Melkhout* ('milk-wood') by the settlers.

Ironwood, a city of Michigan, 150 miles W. of Marquette, with large iron-mining and lumbering interests; pop. 16,000.

Irony (Gr. *eirōneia*; *eirōn*, 'a dissembler'), the name applied to a figure which enables the speaker to convey his meaning with greater force by means of a contrast between his thought and his expression, or, to speak more accurately, between the thought which he evidently designs to express and that which his words properly signify. It may be employed to convey assent and approbation as well as the contrary, but it is more properly a weapon belonging to the armoury of controversy, by means of which weight and point may be added to the gravest part of the argument. The dialogues of Plato are admirable examples of a subtle *dialectic* irony, in which the opinion of the adversary is put respectfully in the foreground, and the appearance of deference is never dropped until the supports on which it rests are one by one withdrawn, and the whole is completely undermined and seems to sink by the weight of its own absurdity. Of this rare art in modern literature there is nothing worthy of comparison, save the *Provincial Letters* of Pascal. A more recent master of dialectic irony is the Danish theologian and philosopher, Kierkegaard. Of English writers, Swift and the later Samuel Butler have excelled in irony.

Iroquois, formerly a great confederation of Indian tribes, recognised as a distinct branch of the American family. At the beginning of the 17th century they included the Mohawks, Oneidas, Onondagas, Cayugas, and Senecas, and became known as the 'Five Nations'; in 1715 they were joined by a related tribe, the Tuscaroras, and became the 'Six Nations' of the 'Long House.' Each tribe managed its own affairs, under its own sachems, and a council of fifty sachems met annually and disposed of questions affecting the confederation as a whole. The chiefs, who, like the sachems, were of equal rank, but who owed their position to personal valour alone and did not form a hereditary body, exercised leadership in time of war only. The confederation was found by the earliest settlers in possession of the greater part of the present state of New York, but by the end of the 17th century all the tribes between the Atlantic and the Mississippi, and from the St Lawrence to the Tennessee, had been brought under its influence. With the Dutch, and afterwards with the English, the Iroquois always maintained friendly relations, even taking sides with their allies during the Revolution; to the French, on the other hand, they were bitterly hostile, and their enmity had an important effect in checking the growth of French influence in North America. After the Revolution the Mohawks crossed into Canada under Joseph Brant (q.v.), and are now settled on two reservations to the north of Lakes Erie and Ontario. The Cayugas are scattered, and some hundreds only of the Tuscaroras have found a home among the Mohawks; but most of the Oneidas are settled at Green Bay, Wisconsin, most of the Senecas in Western New York, and the Onondagas still hold their beautiful valley near Syracuse, New York. The Iroquois probably never exceeded 25,000, and they still number about half as many, most of them in the United States. Schools and missions have met with considerable success, and civilisation is making marked progress among the descendants of this remarkable confederation, while some of their number have attained to distinction as soldiers, engineers, &c.

Irradiation. When a bright object is looked at, an image of it is formed on the retina of the eye. The receiving apparatus there consists of a number of separate stimulable elements or sets of elements; and for the maximum distinctness of vision no one

of these elements should be at all affected by stimulation of its neighbours. If, however, the object be brilliant the image on the retina is very bright, and neighbouring sensitive elements participate in the excitement; a bright object thus looks larger than it is. Examples: bright white letters on a black ground look larger than they are; black letters on a bright white ground look smaller; a white-hot wire appears thickened; the new moon appears larger than the copper-coloured 'old moon' which it appears to 'nurse'; and, especially, an electric incandescent lamp often appears, on account of the extreme brilliancy of its attenuated filament, to be almost filled with light. Exner showed (1923) that it is not necessary to assume that neighbouring sensitive elements can participate in a localised excitement; the retinal image is never sharp, and is brightest at its centre; neighbouring elements are always impinged upon, but the marginal brightness may not be sufficient to excite them; if, however, the brightness be sufficiently increased, they also manifest excitement.

Irrational Numbers, a term applied to those numbers which cannot be accurately expressed by a finite number of figures. For instance, $\sqrt{2}$ is an irrational number. If the diameter of a circle is 1 foot the circumference is an irrational number of feet. Irrational numbers have been defined to be numbers which are incommensurate with unity. They are also termed Surds.

Irrawaddy. See IRAWADI.

Irregulars may be defined as troops who have not been trained under the authority of a government, but who have been allowed to train themselves; who have not been raised and organised by order of a government, but often at its invitation, and have been allowed to combine into corps. They may then be, and they generally are, recognised by the authority, are allotted a certain sphere of duty, are more or less supervised by the authority, and are sometimes more or less paid and equipped individually, or subsidised as a corps by a grant to their leader. In time of peace it is usual to find such 'irregulars' on the frontiers of civilised states where these frontiers are up against 'savage' tribes. Thus Great Britain has several bodies of this kind on the north-west frontier of India, where the populations across the border are turbulent hill-men. The irregular corps are, in these cases, raised at our invitation by the chief of some suitable clan, and we grant the chief a subsidy of money and arms and equipments. An important case of this kind is our subsidising of certain Afridi septs in order to keep open the Khaiber Pass.

France and Russia have precisely similar bodies of true irregulars—France in North Africa and Indo-China, Russia in Central Asia. Frequently in history we find a Power trusting to such troops to reinforce its regular army in war, but very seldom indeed has the issue been satisfactory. It has generally been found, as Russia found when fighting Frederick the Great in the Seven Years' War, that the irregulars, especially when they were cavalry, proved in the end more troublesome to their own side than to the enemy—exception being made of their usefulness against an enemy retreating in difficulties, as when Napoleon had to leave Moscow in 1812. The *francs-tireurs* of France in 1870-71 were true irregulars, connived at, and supplied with arms by, the provisional government, not recognised by the Germans as belligerents, but treated as brigands when captured. It is the invaded country, beaten to its knees, that uses these aids to prolong the struggle, usually with the chief result of merely exacerbating the passions aroused by the contest.

Irrigation (Lat., 'watering'), a method of producing or increasing fertility in soils by an arti-

ficial supply of water, or of inundating them at stated periods. Irrigation was probably first resorted to in countries where much of the land must otherwise have remained barren from drought, as in Egypt, where it was extensively practised some millennia before Christ, and where great systems of canals and artificial lakes were formed for the purpose. Extensive works, intended for the irrigation of large districts, existed in times of remote antiquity in Mesopotamia, Persia, India, China, and some other parts of the East; and in such of these countries as have not entirely lost their ancient prosperity such works still exist. Some plants also require a very abundant supply of water, and irrigation has become general where their cultivation prevails. This is particularly the case with rice, the principal grain of great part of Asia. In Europe irrigation prevails chiefly in the south, where it was extensively practised by the Romans.

Irrigation in Britain, where it was hardly practised till the 19th century, and in most parts of Europe except Italy, is almost exclusively employed for the purpose of increasing the produce of grass by converting the land into water-meadows. The value of it, even for this one purpose, does not seem to be sufficiently understood. Poor heaths have been converted into luxuriant meadows by means of irrigation alone. But in the countries in which irrigation is most extensively practised the production of all crops depends on it.

The irrigation of land with the sewage water of towns is, under another name, the application of liquid manure. In no small degree the water of rivers and of springs depends on its organic and mineral constituents for its fertilising properties, so that the application of it is not in principle different from that of liquid manure; but it must be borne in mind that the mere abundance of water itself is of great importance for many of the most valuable plants, as the most nutritious substances brought into contact with their roots are of no use to them unless in a state of solution: whilst it is an additional recommendation of irrigation that the supply of water most favourable to the growth of many valuable plants is destructive of some which in many places naturally encumber the soil, as heath, broom, &c. The water which is used for irrigation should be free from mud and such impurities as mechanically clog the pores of leaves, or cover up the *hearts* of plants, and interfere with their growth. Irrigation is far from being so extensively practised in Great Britain as would seem desirable. There are few farms in the British Isles which would not give a handsome return for artificial watering in a dry year—i.e. if the water could be obtained and applied at a reasonable cost. In many instances the produce might be increased two, three, or even fourfold. The amount of moisture which farm crops require to ensure their full development is greater than would be readily conceived. At Rothamsted it was found by Lawes and Gilbert that an acre of wheat in five months and eighteen days evaporated through its leaves no less than 335½ tons of water. Light porous soils benefit most from irrigation; sandy soils, with a little admixture of clay and marl, usually most of all. Except in tropical countries, stiff retentive clay would not as a rule be benefited by irrigation, and might be injured by it, at any rate for arable farming. Thorough drainage, natural or artificial, is a necessary accompaniment of successful irrigation—necessary so that the soil may not become ‘water-logged,’ but benefited by the water percolating through it. Soil wholly or partially uncovered by vegetation is liable to be robbed of nitrogen by the rain or irrigation water washing nitrates into the drains or down beyond the reach of the plants. This is avoided in grass

land by the roots of the grasses engaging the nitrogen. Irrigation may benefit the land in various ways, most usually (1) by softening and disintegrating the soil in percolating through it; (2) by bringing additional plant food into it; (3) by facilitating the dissolving, preparing, and distribution of the plant food already in the soil; and (4) by the oxidation of any excess of organic matter in the soil, leading thereby to the production of useful carbonic acid and nitrogen compounds. See SEWAGE, MANURE.

The methods most generally pursued are what are known as bed-work irrigation, catch-work irrigation, and subterraneous irrigation. The first method can be conveniently applied only to ground which is nearly level. The catch-work method is very much less costly, and can be applied to land whether it is level or not. By the last system the soil is saturated with water from below.

In some parts of the United States irrigation is of vital importance. In the east the principal use of irrigation is in the rice-fields of South Carolina and Georgia; but such western states as Colorado and Utah are altogether dependent on it, owing to the scarcity of the rainfall. In 1902 a reclamation act was passed giving the United States government power to carry out extensive irrigation schemes. It is calculated that over 60,000,000 acres of unproductive land west of the 100th meridian are capable of reclamation, and great progress has been made in Arizona, Nebraska, Wyoming, Montana, Oregon, Nevada, Idaho, Colorado, South Dakota, New Mexico, and California.

In Australia irrigation has transformed hundreds of thousands of acres, once covered with scrub, into rich pastoral, agricultural, and fruit-growing land. In part this has been accomplished by means of Artesian Wells (q.v.), in part through the initiation of river irrigation schemes on a scale comparable with similar great works in the valley of the Nile. Notable among operative river schemes are those on the Murray, Mitta Mitta, Goulburn, and Murrumbidgee rivers. The Goulburn scheme serves an area of nearly a million acres, while that on the Murrumbidgee, with its great dam at Burinjack and weir at Narrandera, provides for the irrigation of about one and a half million acres; at Yanco near the weir is a state experimental irrigation farm. The importance of irrigation there is noticed in the article on the Cape of Good Hope; for their irrigation works, see the articles INDIA, CEYLON. Egypt (q.v.) is the land most entirely dependent on systematic and careful irrigation; see ASSUAN, NILE.

In cultural anthropology Professor Elliot Smith and his school, following Professor Cherry, lay great stress on irrigation as an element in the archaic civilisation which, according to their teaching, spread from Egypt over a great part of the world.

Irish, a river of Asia, the chief affluent of the Ob (q.v.), rises at the east end of the Altai Mountains, passes through Lake Saisan, breaks through the Altai in the west at the bottom of a savage gorge, and flows north-westwards across the steppes of Western Siberia to join the Ob, from the left, at Samarow. At that point it has a width of 2000 yards; its total length is 1620 miles; the area of its basin, 647,000 sq. m. The important towns of Semipalatinsk, Omsk, and Tobolsk stand on its banks. From April to November it is navigable from its mouth as far as Lake Saisan; during the rest of the year traffic is carried on by means of sledges. Its current is gradually shifting eastwards. Its best-known tributaries are the Buchtarma and Om from the right, and the Tobol and Ishim from the left.

Irún, a Spanish frontier town on the Bidasoa, 20 miles SW. of Bayonne. It is on the highway of

overland communication, and has mineral springs, and ironworks, potteries, and paper mills. In 1837 General Sir De Lacy Evans (q.v.) captured it from the Carlists. Pop. 14,000.

Irvine, a seaport of Ayrshire, on the river Irvine, $1\frac{1}{2}$ mile from the Firth of Clyde, and 11 miles by rail N. of Ayr, 29 SW. of Glasgow. Its harbour has been much improved since 1873, and there are shipyards, railway and engineering works, forges, chemical works, sawmills, &c. The bridge (1746, improved 1837 and 1888), the new town hall (1859), the parish church (1774), the mercat cross (taken down 1694, restored 1921), Seagate Castle (12th-16th century), statues of Lord-justice general Boyle (1867) and Burns (1896), and the academy (1814, new building, 1900), are features of the town. Irvine became a royal burgh about 1230, and in 1881 was extended to include Fullarton. With Ayr, &c., it returns one member to parliament. The town was active in the wars of Independence, during the 17th and 18th centuries was one of the leading ports of Scotland, and here in the plague years (1645-47) the staff and students of the university of Glasgow were housed. It was the birthplace of Galt and James Montgomery, and has memories also of Burns and the Buchanites. Pop. (1841) 4594; (1891) 9086; (1921) 11,826.

Irving, EDWARD, was born in the town of Annan, Dumfriesshire, August 4, 1792, and at thirteen entered the university of Edinburgh. In 1810 he became a schoolmaster at Haddington, in 1812 at Kirkcaldy, where three years later he was licensed to preach; and in 1819 he was appointed assistant to Dr Chalmers, then a minister in Glasgow. His sermons did not prove very popular; Chalmers himself was not satisfied. In 1822 Irving accepted a call to the Caledonian Church, Hatton Garden, London. His success as a preacher in the metropolis was such as had never previously been witnessed. After some years, however, the world of fashion got tired of Irving; but it was not till his more striking singularities of opinion were developed that fashion finally deserted him. At the close of 1825 he began to announce his convictions in regard to the second personal advent of the Lord Jesus, in which he had become a firm believer, and which he declared to be near at hand. This was followed up by the translation of a Spanish work, *The Coming of the Messiah in Majesty and Glory*, by Juan Josafat Ben Ezra, which professed to be written by a Christian Jew, but was in reality the composition of a Spanish Jesuit. Irving's introductory preface is regarded as one of his most remarkable literary performances. In 1828 appeared his *Homilies on the Sacraments*. He now began to elaborate his views of the incarnation of Christ, asserting with great emphasis the doctrine of his oneness with us in all the attributes of humanity. The language which he held on this subject drew upon him the accusation of heresy; he was charged with maintaining the sinfulness of Christ's nature. But he paid little heed to the alarm thus created. He was now deep in the study of the prophecies, and when the news came to London in the early part of 1830 of certain extraordinary manifestations of prophetic power in the west of Scotland, Irving was prepared to believe them. Harassed, worn, baffled, Irving was arraigned before the presbytery of London in 1830 and convicted of heresy, ejected from his new church in Regent's Square in 1832, and finally deposed in 1833 by the presbytery of Annan, which had licensed him. His defence of himself on this last occasion was one of his most splendid and sublime efforts of oratory. The majority of his congregation adhered to him, and gradually a new form of Christianity was developed, commonly

known as Irvingism, though Irving had really very little to do with its development (see CATHOLIC AND APOSTOLIC CHURCH). Shortly after his health failed, and, in obedience, as he believed, to the Spirit of God, he went down to Scotland, where he sank a victim to consumption. He died at Glasgow, 8th December 1834, in the forty-second year of his age. See Carlyle's *Miscellaneous Essays* and his *Reminiscences*, and Mrs Oliphant's *Life of Edward Irving* (1862).

Irving, SIR HENRY (born JOHN HENRY BRODRIBB), actor, was born in 1838 at Keinton-Mandeville, Somerset. Educated in London, he was for a time engaged as a clerk in the city, but, having a strong inclination for the stage, made his first appearance at the Sunderland Theatre in 1856. After next playing at Edinburgh for nearly three years, he first performed in London on September 25, 1859, at the Princess's Theatre. He achieved but a moderate success, though some dramatic readings which he gave at this time at Crosby Hall were warmly commended by the critics. He next played at Glasgow, and then for nearly five years at the Manchester Theatre Royal. After a brief engagement at Liverpool in 1866 he appeared with Miss Kate Terry at Manchester in *Hunted Down*. An invitation to London followed, and he appeared at St James's Theatre with much success as Doricourt in *The Belle's Stratagem*, Dornton in *The Road to Ruin*, and (at the Gaiety) as Mr Chenevix in *Uncle Dick's Darling*. Performances at other London theatres followed, and in 1870, at the Vaudeville Theatre, he made a distinct mark as Digby Grant in Albery's comedy of *The Two Roses*. Migrating to the Lyceum in November 1871, he further added to his reputation by his fine representation of Mathias in *The Bells*. Other impersonations succeeded, including Charles I., Eugene Aram, Richelieu, and Louis XI., until, in 1874-5, during a run of two hundred nights, he established his reputation as a tragedian of real power and originality by his unconventional and much discussed performance of *Hamlet*. Among other successes under Mrs Bateman's management of the Lyceum were *Macbeth*, *Othello*, *Richard III.*, and *The Lyons Mail*. In 1878 Irving entered upon his memorable management of the Lyceum (for twenty-one years), where his triumphs were shared by Miss Ellen Terry. After *Hamlet*, *Othello*, and *The Merchant of Venice*, which was marked by scenic as well as histrionic excellence, he appeared in 1880 in *The Corsican Brothers*; in Tennyson's drama of *The Cup* in 1881; in *Romeo and Juliet* and *Much Ado about Nothing* in 1882; *Twelfth Night* in 1884; W. G. Wills's *Olivia* in 1885; *Faust*, adapted by Wills, in 1886; *The Dead Heart* in 1889; *King Lear* in 1892; *Becket* in 1893; *King Arthur* in 1895; *Cymbeline* in 1896; *Peter the Great* by his son, Laurence, in 1897. From 1883 Irving and his company were repeatedly received with enthusiasm in the United States. In 1895 he was knighted, the first actor to receive the distinction. He died 14th October 1905, and, after cremation, was buried in Westminster Abbey. Notwithstanding certain mannerisms of voice, gait, and gesture, he was undoubtedly at the head of contemporary English actors, and did much to redeem the stage from formality and mediocrity. His two sons, HENRY BRODRIBB (1870-1919) and LAURENCE SYDNEY BRODRIBB (1871-1914), though educated for other professions, the elder for the bar (he was called in 1894), the younger for the diplomatic service, both found careers on the stage. A student of criminology, Henry also wrote works on that subject.

Irving wrote *The Drama* (1893), and published several addresses. See Clement Scott's *Drama* (1899) and works on Irving by Joseph Hatton (1884), Frederic Daly (1884),

William Archer (1885), Percy Fitzgerald (1893), Hiatt (1899), Bram Stoker (1906), and Austin Brereton (1908), who also wrote on the sons (1922).

Irving, WASHINGTON, was born in the city of New York, 3d April 1783, and died at Tarrytown, New York, 28th November 1859. His father's family were Scottish, and claimed descent from William de Irwyn, secretary and armour-bearer of Robert Bruce; his mother was English, attached to the Episcopal Church, and of a loving, sunny temper. His education was scanty and desultory. His brothers were sent to college, but he showed no inclination to study, being 'a dreamer and a saunterer.' This arose in part from his tendency to pulmonary disease. He began to read law at the age of nineteen, but after two years, his health being precarious, his brothers sent him to Europe. He landed at Bordeaux in 1804, and went by Marseilles to Italy, escaping with difficulty from Bonaparte's police, who persisted in regarding him as an English spy. At Rome he was intoxicated by Italian art, and having met Allston, the American painter, was tempted to become an artist, but thought better of it. He visited Paris, the Netherlands, and London, where he saw John Kemble and Mrs Siddons. In 1806 he returned to New York in improved health, and was admitted to the bar. Those were 'Corinthian days,' and he led a rather idle life; much in society, and greatly admired.

His first writing was in the *Salmagundi*, a semi-monthly sheet in imitation of the *Spectator*, conducted jointly by himself, his brother William, and J. K. Paulding. It ran for twenty numbers, and then stopped without explanation in the fullness of success. There was considerable merit of a superficial sort in those early attempts, but there was no evidence of a serious literary purpose, for the papers apparently were written with a view only to social distinction. His first characteristic work, and the one by which he will be best known to posterity, was *A History of New York, by Diedrich Knickerbocker*, published in 1809. All readers of English know the little man in knee-breeches and cocked hat as one of the permanent figures in the gallery of literary portraits. The *History* has some grains of truth, but is openly a good-natured burlesque upon the old Dutch settlers of Manhattan Island. The humour and the gravity which mask it are alike irresistible. It may be doubted if there is in the language a more delightful or more perfectly-sustained piece of drollery. Readers of Scott will remember his warm praise of the book, written while 'his sides were sore with laughing.' In the United States it was universally read; and so abiding has been the impression that it is far oftener quoted than any sober historical work. It is to the American people as *real* in its way as the *Pilgrim's Progress*.

For many years after this Irving was in partnership with his brothers in a mercantile business that had relations on both sides of the Atlantic; but in the end they were unsuccessful; and when later he had won his place among authors and was receiving a good income, he supported two of his brothers and five nieces with unselfish devotion. In May 1815 he went to Europe for the second time, and did not return for seventeen years. It was in 1818 that the misfortunes of his firm culminated in bankruptcy, and thereafter he turned his whole attention to literature. He declined liberal offers for magazine work, and would undertake nothing that was to interfere with his plans. The first number of the *Sketch Book* appeared in New York in 1819, and the last in 1820. It was received in the United States with universal delight. Its early success in Great Britain was largely due to the powerful support of Scott. All the pieces

in this miscellany have a certain charm—if for nothing more, for their felicitous touch and purity of style. The chief interest, however, centres in 'Rip Van Winkle,' 'The Legend of Sleepy Hollow,' and 'Westminster Abbey.' The last is one of the most finished descriptive essays of its century, though perhaps a little lacking in simplicity. The two legendary tales are in a way related to the *History of New York*, and have had a currency and an influence difficult to measure. 'Rip Van Winkle' is a distinct creation of genius, and with its fellow has made the lower reach of the Hudson classic ground. For the first time there had been produced in the United States a literary work on the highest level of contemporary excellence. *Bracebridge Hall* (1822) fairly maintained but did not raise the author's reputation. It was scarcely necessary, for 'Geoffrey Crayon, Gent.' was already at the summit of favour. After a few years passed on the Continent he published (1824) *Tales of a Traveller*, a work which he thought his best in regard to style, but which some consider to be over-refined.

In 1826 he went to Spain and began the long and arduous studies which were the foundation of his more important serious works. These were *The Life of Columbus* (1828), *Conquest of Granada* (1829), *Voyages of the Companions of Columbus* (1831), *The Alhambra* (1832), *Legends of the Conquest of Spain* (1835), *Mahomet and his Successors* (1850). The last two or three of the works just named were only sketched or partly written before his return to the United States in 1832, but they are given together with the group of which they form part. It was Irving who first revealed to English readers the rich stores of Spanish history and romance; and whatever may be done to correct or enlarge his relations, to him must be given the praise of having produced some of the most fascinating books in existence. He had intended to write the history of the conquest of Mexico, for which he had collected materials, but generously, and to his own loss, relinquished his design to Prescott when he learned that the latter proposed to undertake it. At the end of this sojourn in Spain Irving was for a short time secretary to the United States Legation in London. On his return to his native city (1832) he was received with great enthusiasm. He declined political honours, and continued his literary work. Having made an excursion in the then Far West, he published (1835) *A Tour on the Prairies*. In the same year he published *Recollections of Abbotsford and Newstead Abbey*. He was also at work upon the last of the books in the Spanish series. In writing *Astoria* (1836) he was assisted by his nephew, his future biographer. *The Adventures of Captain Bonneville* (in the Rocky Mountains) appeared in 1837. His biography of Goldsmith was mainly written about this time, though not published until 1849. He remodelled for his own residence an old Dutch house near Tarrytown, near the scene of his legend of Sleepy Hollow. This became well known in after years under the name of Sunnyside. But his intended retirement was postponed by his appointment in 1842 as United States minister to Spain. He returned in 1846 and once more set himself to work. *Goldsmith* and *Mahomet* appeared as already mentioned; then, in 1855, *Wolfert's Roost*, a miscellany. His last work was the *Life of George Washington* (5 vols. 1855-59).

Sentiment and abundant humour characterise his writings; but above all, he had the power to seize the attention of cultivated readers by his keen observation, his graphic touches of description, and his limpid and musical style. The early books which first gave him fame, and those which came from his studies in Spain, are the best, for in

them his genius is conspicuous. The latter productions are respectable, but would not have given him the high rank he deservedly holds. His *Life* was written by his nephew, Pierre M. Irving (5 vols. 1862-64), and by G. S. Hellman (1925). There is also an excellent short biography by C. D. Warner (1881).

Irvingia, a small genus of tropical African trees of the natural order Simarubaceae, with alternate simple coriaceous leaves and small fragrant yellow flowers. *I. Barteri* is the wild mango, dika-bread, or bread-tree of western Africa; the seeds are eaten, and also contain an oil or fat used by the natives in cooking.

Irvingites. See CATHOLIC AND APOSTOLIC CHURCH.

Isaac, one of the Hebrew patriarchs, the son of Abraham and Sarah, and half-brother of Ishmael. His story in Genesis makes him born when both his parents were advanced in age, and die at Hebron at the age of 180, leaving two sons, Jacob and Esau. The Midrash ascribes to him, in allusion to Gen. xxiv. 63, the institution of the afternoon prayer.

Isaac I., COMNENUS, emperor of Constantinople, was the first of the Comneni who attained to that dignity. Under the successors of Basil II. Isaac served in the army, winning the hearts of officers and men by his prudence and uprightness, and on the deposition of Michael VI. in 1057 was elevated to the throne. He established the finances of the empire on a sounder and more stable footing, and, braving the patriarch's threat of excommunication, even laid the clergy under contribution at the tax-collections. He repelled the Hungarians attacking his northern frontier; and then, resigning the crown (1059), retired to a convent, where he lived two years longer. He was one of the most virtuous and able emperors of the East. There are extant from his pen scholia and other works on Homer.

Isaac II., ANGELUS, connected through his mother with the Comnenian emperors, became sovereign of the East in 1185, and reigned ten years. Isaac was a vicious and cowardly prince, and his reign was a period of war and tumult. He was dethroned, blinded, and imprisoned by his brother Alexius in 1195. Eight years later he was restored to the throne, and reigned for a period of six months, when he was again dethroned, and soon after he died in prison.

Isabella of Castile, queen of Spain, born on 23d April 1451, was the daughter of John II., king of Castile and Leon, and in 1469 married Ferdinand V., 'the Catholic,' king of Aragon. See FERDINAND, and books by Hare (1906) and Miss Plunket (1919).

Isabella II. (MARIA ISABEL LUISA), queen of Spain (q. v.), elder daughter of Ferdinand VII., was born 10th October 1830, and died in April 1904. See work by F. Gribble (1913).

Isabey, JEAN BAPTISTE, French portrait-painter, was born at Nancy on 11th April 1767, and studied under David. He painted portraits of several of the notabilities of the Revolution. Afterwards he became court-painter to Napoleon, and later to the Bourbons. He excelled also as a miniature-painter and as a painter on porcelain. Apart from portraits his 'Isabey's Boat' (1796), and 'Review of Troops by the First Consul' (1804), are notable. He died at Paris, 18th April 1855. See *Life* by Taigny (Paris, 1859). His son, Eugène (1804-86), was a clever historical painter.

Isæus is, like Wordsworth's cuckoo, 'a voice, a mystery,' for, though we have ten of the fifty speeches he composed, we know absolutely nothing

of the facts of his life, except that he pursued the profession of speech-writer in Athens, and that his first speech was composed in 389 B.C. and his last in 353 B.C., so that he may be said to have lived from the time of the Peloponnesian war to that of Philip's supremacy. Isæus did not compose political speeches, or speeches to be delivered in public suits, but exclusively speeches for private suits. His strength as a lawyer lay in his power of dealing with cases of inheritance, and it is fortunately those of his speeches which deal with this branch of Attic law that have survived to our times. To the student of Aryan institutions and of comparative law, as well as to the student of Attic law, they are invaluable. To the general reader they are less interesting, for the very nature of the cases in which they were delivered—disputes as to *meum* and *tuum*—forbade any very lofty flights of eloquence. On the other hand, the functions which he discharged in the history of Greek oratory as a branch of literature were of the utmost importance, and explain the fact that he was included in the 'canon' of the ten great Greek orators. It was through Isæus that the change from the older style of Lysias to the new school of which Demosthenes is the greatest representative was effected. He imitated Lysias, and was himself the teacher of Demosthenes. It will be remembered that Demosthenes' first speeches were those delivered by him in his efforts to recover his inheritance, the branch of the law in which Isæus was acknowledged master. The characteristics of the two schools between which Isæus was the connecting link are to be seen in the natural tones of Lysias contrasted with the technical skill of the professional orator which along with higher gifts marks Demosthenes. The importance of this contrast becomes apparent when it is remembered that the speech-writer or logographer was not allowed by Athenian law to speak himself on behalf of his client, but only to compose speeches to be delivered by his client. When speech-writing first became a profession and a branch of literature—i.e. about the beginning of the Peloponnesian war—there was a prejudice in the mind of the average Athenian jurymen against the use of speeches thus written, which made it desirable that the speech should have the appearance of being the speaker's own composition. In adapting his style to the character of his client for the time being Lysias was unrivalled. By the time of Demosthenes the practice of logography was so usual that attempts at disguise were less necessary; and the speech-writer might display all the technical skill of oratory without arousing suspicion. Isæus endeavours to imitate the unprofessional and innocent style of Lysias, but does not succeed in concealing the hoof of the advocate: his simplicity is exaggerated, his sentences have not the careless ease of Lysias, but an ungraceful negligence. At the same time we find in him the germs of that combination of practical utility and artistic beauty which was afterwards to mark the new school. Isæus surpasses Lysias, as he is himself surpassed by Demosthenes, in pure oratorical skill. Lysias is distinguished for simple colouring but graceful drawing, Isæus for careless drawing but deeper shade, brighter light, and greater wealth of colour.

See Blass's *Attische Beredsamkeit* (1893); Jebb's *Attic Oratory* (1893); and especially *The Speeches of Isæus, with Critical and Explanatory Notes* by William Wyse (1905).

Isaiah (Heb. *Yeshai'ah*), son of Amoz, first of the greater Hebrew prophets, was a citizen of Jerusalem, who came forward as prophet about 740 B.C. (probable death-year of King Uzziah), and exercised his office till at least the close of the century. The main object of his prophesying was his people, Israel, sunk in social unrighteousness

and idolatry; the subject was his people's God, Yahweh, *exalted* or sovereign in *righteousness*, and, because there is nothing higher than righteousness, supreme over the whole world and its forces. From such a God to such a people only punishment could pass, and the means for this was present in the great world-power of the day, the Assyrians, four (or possibly five) of whose invasions of Palestine Isaiah predicted and lived to see. Because, however, Yahweh's honour and the existence of true religion upon earth were identified with the continuance of Israel's national history, Isaiah promised the survival of a *remnant*, the stock of a spiritual nation in the latter days, and centre for a whole world converted to Yahweh. This *remnant* required a leader and a rallying-place; and it was on these two points that Isaiah's eloquence and hope reached their climax: that a great prince should arise in Judah—though sometimes he described the future without this personage—and that Zion, though closely besieged, should remain inviolate. These promises, however, are subordinate to the spiritual principle, of which Isaiah was probably the earliest prophet, that without faith in a righteous God there can be no security or welfare for a people—'if ye will not have faith ye shall not have *staiith*' (vii. 9). But he also insists on practical wisdom and political sagacity as needful, even as (he says) 'God also is wise, wonderful in counsel, and excellent in the quality which carries things through' (xxxi. 1-3, xxviii. 29).

In the book of his name, the prophecies generally admitted to be Isaiah's (though, like all the prophetic books, with glosses and even longer passages of later date) do not lie in chronological order. They may be re-arranged according to the four or five invasions of Palestine: Tiglath-pileser's, 734-32; Shalmaneser's and Sargon's, 725-20; Sargon's, 711-10; Sennacherib's, 701, and possibly again about 690. (1) In passages held to refer to times prior to the first invasion (ii.-x. 4; v. 25-30 is in immediate sequence to ix. 8-x. 4: some add x. 5-34 and xvii. 1-14) Isaiah describes his call, arraigns both states of Israel, intimates their invasion, but with a different result for each. To north Israel he holds out no hope: in the worst that can happen to Judah (though it also deserves invasion because of the foolish trust of its people in material things), Zion shall stand, and David's dynasty survive in a prince, whose birth Isaiah predicts as almost immediate, whom he hails as a deliverer from the Assyrians, but his ascriptions to whom are applied by the New Testament and Christian theology to Jesus Christ. For these Messianic oracles (ix. 1-7, with their fellows in xi. 1-9, xxxii. 1-8) some recent critics (Hackman, Cheyne, Volz, Marti) have argued for another authorship and a later date than Isaiah's; but their reasons are far from conclusive, while the effects which the oracles in question ascribe to the work of the Messiah are just the two for which Isaiah himself hoped and laboured, the deliverance of the people from foreign oppression and the restoration among them of justice and a pure civic life, and do not include what prophets during and after the exile predict, viz. the return of the exiles both from Egypt and Mesopotamia (xi. 10-16 is, of course, a post-exilic addition). Tiglath-pileser retired, taking only a small part of north Israel captive. (2) In prophecies of the next invasion (xxviii. and most probably x. 5-xi.) Isaiah repeated the doom of north Israel, and his word was vindicated by the fall of Samaria in 721 and captivity of the people. He warned Judah again, but defied the Assyrian to take Zion, and expanded his prospect of the coming prince and the glory of the nation. Hezekiah, his friend, was now on the throne, and their joint work of abolishing the idols

may have begun. (3) About the invasion of 711-10 there is difficulty. Did it comprise Judah? Sayce, Cheyne, &c., said it did, and assigned to it Isaiah, x. 5-34, xxii., and xxxvi. 1, where they read *Sargon for Sennacherib*. But of an invasion of Judah by Sargon we have no direct evidence, and hence other critics (Driver, Robertson Smith, &c.) assign to this period only xx., xxi. 1-10, perhaps xvi. 13-14 (the rest of xv.-xvi. being earlier), and the events in xxxviii. and xxxix. (4) With 705—the revolt of Sargon's vassals against Sennacherib, his successor, and Sennacherib's preparations to reduce them—we reach the most fertile period of Isaiah's prophesying. In xxix.-xxxii. he denounces Jewish intrigues with Egypt, predicts the siege and deliverance of Zion, and promises to faith and sincerity a glorious future. In another set of oracles to foreign nations, not all dating from this time, xiv. 24-32, perhaps xvii. 12-14, xviii., xix., xxi., xxiii., he intimates to a number of tribes the futility of their resistance to Assyria, and affirms that only Zion shall stand. In 701 Sennacherib overran Judah, but desisted from his blockade of Jerusalem on payment of tribute by Hezekiah. So much is clear from Sennacherib's own declaration (the Taylor-Cylinder) and from 2 Kings, xviii. 13-16. The latter passage is followed, however, by two further accounts of Sennacherib's operations—2 Kings, xviii. 17-xix. 8 parallel to Isaiah, xxxvi. 2-xxxvii. 8, and 2 Kings, xix. 9-37 parallel to Isaiah, xxxvii. 9-38. Are these pairs of passages different versions of the same operations, or accounts of two successive expeditions? And do they refer only to the events of 701, or is the second pair to be referred to a *fifth* Assyrian invasion under Sennacherib about 690? These questions still await certain answers; but, however they be answered, it is clear that Jerusalem was, either once or twice, saved from capture and overthrow by an Assyrian army; and thus Isaiah's faith and words were gloriously vindicated by events. The prophecies during the campaign or campaigns of Sennacherib are probably chap. i. on the devastation of Judah, and xxii. 1-14 on the panic and profligacy excited in the capital by the appearance of the foe before its walls; and less probably x. 28-34 (which, indeed, may be a forecast of any of the expected Assyrian invasions), and still less probably xxxiii., held by some to be the prophet's triumph, on the Assyrian withdrawal, but by others not to be Isaiah's at all. After this triumph it is very uncertain that we have anything more from Isaiah, except it be the latter half of xix., which has been called his 'swan-song.' Of his end we know nothing: a tradition exists that he was slain to death in the persecution of Manasseh (cf. Epistle to Hebrews, xi. 37; Gemara, Jebamoth, 49 b, and Sanh. 103 b; Joseph. *Antiq.*, x. 31, 38).

There still remains a large portion of the Book of Isaiah, xiii.-xiv. 23, xxiv.-xxvii., xxxiv., xxxv., and xl.-lxvi. The first doubts as to the authenticity of these were started by Aben-Ezra, and followed up by Koppe (1779), who suspected that xl.-lxvi. were of later date, and after him by an increasing, and now the main, body of critics on the Continent and in Britain—Gesenius, Hitzig, Ewald, A. B. Davidson, Cheyne, Driver, Robertson Smith, Kuenen, Wellhausen, G. A. Smith, Skinner, Gray, &c.; and to a less degree, Delitzsch, Bredenkamp, Orelli, &c. No critic of any eminence now claims all sixty chapters for Isaiah; and indeed the belief that they were all his could only have originated through the taking for granted that the title of chap. i. covers the whole book—an opinion falsified by the appearance of titles for some of the following chapters and their absence from others. None of the chapters in question, save xiii., claim to be Isaiah's, and that they are not his may be argued,

apart from the uncertain and confusing testimony of style, vocabulary, &c., upon grounds of historical evidence. The circumstance and horizon of these prophecies are entirely different from those of the authentic oracles. Assyria is no more the dominant world-power, nor Zion the inviolate fortress of God. The Jews are not in their own land: they are either in exile or just returned. It is no more the repulse of the invader or the recovery of Zion from siege that is predicted; but the overthrow of the tyrant in his own land, the redemption of a captive people, the laying down of a highway for the return of exiles, the rebuilding of the city, and the resumption of worship. Exile is not foretold, nor the effort made to lift the imagination to it as certain. It is described as present: the people are addressed as in exile, their conscience is appealed to as the conscience of a people who have suffered and acknowledge their penalty. In the case of xl.-lxvi. there is an additional argument. In some of these chapters Cyrus, who appeared about 550, or more than a century after Isaiah's death, is not only named as the deliverer of the exiles, and described as existing in the flesh; but in a debate (chaps. xli. ff.) about Yahweh's righteousness—i.e. his fidelity to his ancient promises of deliverance and his ability to perform them—Cyrus is presented both to Jew and heathen as a living proof that these promises are about to be fulfilled—which surely would have been an utterly vain proceeding if Cyrus were not already there, visible to all men. This very definite evidence overbears not only any resemblances in style between xl.-lxvi. and Isaiah's own oracles, but also such doubtful facts as that Isaiah foresaw the Babylonian captivity (xxxix.), or that he once wrote from the standpoint of a much larger exile than happened in his own day (xi.). It is quite possible, though incapable of proof, that the disputed prophecies contain fragments from Isaiah himself. That they contain at least pre-exilic fragments is more certain: lvi. 9-lvii. 11 implies that the Jewish state still exists, and bears traces of an origin in Palestine. By some the passages on the Servant of the Lord are assigned (not conclusively) to a different hand from the rest, and (much more probably) chaps. lvii. 12-lxvi. are held to be post-exilic. Originally in the Jewish canon the Book of Isaiah seems to have followed Ezekiel, a fact which tends to confirm the late date of at least parts of the book.

The best Commentaries are by Ewald, Dillmann, Duhm (1892) Skinner ('Camb. Bible for Schools,' 1896-98), Whitehouse ('Century Bible'), Marti (1900), and G. B. Gray (chaps. i.-xvii. only, 1912). Among other works are Driver's *Isaiah: his Life and Times* ('Men of the Bible' Series, 1888); G. A. Smith, *Isaiah* ('Expositor's Bible,' 1888-90), *Jerusalem*, ii. chaps. 5, 6; Cheyne, *Introduction to the Book of Isaiah* (1895); Box, *Book of Isaiah* (1908). See also Matthew Arnold's two vols. on Isaiah.

Isambert, FRANÇOIS ANDRÉ, French lawyer, was born at Aunay (Eure-et-Loire) on 30th November 1792. In 1818 he began to practise as an advocate at the Court of Cassation in Paris. Here he soon made a name as a political advocate, ranging himself in opposition to the Restoration government. About this time he greatly enhanced his reputation by publishing *Recueil Général des Anciennes Lois Françaises* (29 vols. 1821-33), *Traité du Droit Public et du Droit des Gens* (5 vols. 1823), and *Code Electoral et Municipal* (2d ed. 1831). He also interested himself actively in the condition of the liberated slaves in the French West Indian colonies. After the July revolution of 1830 he was appointed councillor of the Court of Cassation and elected a member of the Chamber of Deputies. From this year down to 1848 Isambert belonged to the Constitutional opposition, signalling himself as a friend of liberty and an opponent of the Jesuits.

The chief literary productions of the later part of his life are *État Religieux de la France et de l'Europe* (1843-44) and *Histoire de Justinien* (1856). His *Pandectes Françaises*, a collection of French laws, edicts, and ordinances, from 1789 onwards, was left unfinished. Isambert died at Paris on 13th April 1857.

Isandula, or ISANDHLWANA, in the north-east of Natal, on the left bank of the Buffalo River, 110 miles N. by W. of Durban. There, on 22d January 1879, the British camp, comprising four companies of the 24th, with a native contingent, under Colonels Durnford and Pulleine, was surprised by 18,000 Zulus in Lord Chelmsford's absence and almost annihilated. The British loss exceeded 800, that of the Zulus 2000.

Isar, or ISER, a river of Bavaria, rises in the Tyrol, north-east of Innsbruck, and flows 220 miles, generally in a north and north-east direction, till it falls into the Danube near Deggendorf. Munich and Landshut are on the banks 'of Isar, rolling rapidly.' Hohenlinden (q.v.) is 20 miles away. In the first part of its course it is an impetuous mountain-torrent; and even after it leaves the Alps it has many rapids and islands. Large quantities of wood are floated down the Isar from the mountains. Area of its drainage basin, 3545 sq. m.

Isauria, in ancient geography, a district of Asia Minor, occupying the summit and northern slopes of Mount Taurus. The people were stern and savage, like their native mountains, and occupied themselves principally in robbery and piracy. At length their depredations and those of their neighbours, the Cilicians, became so formidable that the Roman proconsul, P. Servilius, chased them into their mountain fastnesses and coerced them into submission in 76 B.C., for which exploit he acquired the surname Isauricus. Nevertheless the Isaurians were not subdued. Pompey, in warring against the Mediterranean pirates, drove them off the sea; but they soon returned again. Indeed so far was their power from having been broken that they conquered the Cilicians, and remained the terror of the neighbouring states down to the 4th century. In the reign of the Emperor Gallienus (253-268) there even arose among this savage folk a rival emperor, Trebellianus, who, however, was finally crushed. This same people also gave two emperors to Byzantium, Zeno I. (474-491) and Leo III. (718-741); the descendants of the latter ruled over the empire of the East for three generations. From the 5th century onwards the Isaurians gradually disappear from history.

Ischia (the ancient *Enaria* and *Pithecura*), an island on the north side of the entrance to the Bay of Naples, 6 miles from the mainland. Area, 20 sq. m.; population, 25,000. Ischia is a favourite place of summer resort, being noted for the excellence of its warm mineral waters, the great richness of its soil, the exquisite flavour of its fruits and wines, and the enchanting character of its scenery. Its highest point is the volcanic Monte Epomeo, 2608 feet, the last outbreak of which occurred in 1302. In 1881 Casamicciola was nearly destroyed by two earthquake shocks. A still more dreadful catastrophe befell it on 28th September 1883, when the town was utterly overwhelmed, only four or five buildings being left standing, and about two thousand persons lost their lives. The inhabitants grow fruits, wine, and olive-oil, and carry on fishing. Chief towns: Ischia (8000), a bishop's seat, and Casamicciola (3000). See Johnston-Lavis, *The Earthquakes of Ischia* (Naples, 1886).

Ischium. See PELVIS.

Ischl, a town of Upper Austria, surrounded on all sides by gardens, is finely situated, 1536 feet

above sea-level, on the river Traun, amid magnificent Alpine scenery, 33 miles E. by S. of Salzburg. It is the chief town of the district called the Salzkammergut (q.v.). The situation of Ischl, and the saline baths, established in 1822, attract thousands of visitors annually. The late Austrian imperial family had a villa there. Salt is manufactured in works opened in 1871. Pop. 10,000.

Isegheem, a town of Belgium, 10 miles by rail N. by W. of Courtrai, has linen and lace manufactures, and a pop. of 14,000.

Iseo, LAKE (*Lacus Sebinius*), a lake of Northern Italy, between the provinces of Bergamo and Brescia. Length, 12½ miles; maximum breadth, 3½ miles; area, 24 sq. m. It has two small islands, and is fed by the Oglio, a tributary of the Po.

Isère, a department in the south-east of France, round which on the north and west flows the river Rhone. It was formed out of the ancient province of Dauphiné. Area, 3200 sq. m.; pop. (1872) 575,784; (1886) 581,680; (1921) 525,522. The surface is level in the north-west, but becomes mountainous and picturesque in the east and south-east. Mont du Midi, on the south-eastern border, rises to 13,088 feet. The chief river, besides the Rhone, is its left-hand tributary, the Isère, which, rising in the Alps at an altitude of 7540 feet, flows south-westwards to join the Rhone above Valence, after a total course of 180 miles (102 navigable). The products include wheat, wine, stone fruits, medicinal plants, and hemp. Cheese is made; and silkworms are reared. The department is rich in mineral products; iron and coal are worked, as also marble, slates, lead, and gypsum. The industrial activity is considerable, particularly in the manufacture of iron and steel goods, gloves, silk stuffs, cloth, linen, paper, straw-hats, liqueur (Chartreuse), &c. The department contains four arrondissements—Grenoble, La Tour-du-Pin, St Marcellin, and Vienne; capital, Grenoble.

Iserlohn, a manufacturing town of Prussia, in Westphalia, on a tributary of the Ruhr, 14 miles S.E. of Dortmund. The industry is chiefly in hardware, especially brass and bronze articles. The calamine mines are celebrated. In the neighbourhood is the Dechen stalactite cave, 292 yards long, discovered in 1868. Pop. (1875) 16,868; (1919) 29,263.

Isernia (anc. *Asernia*), a town of Italy, in the Apennines, 52 miles N. of Naples. It is surrounded by walls, built on the cyclopean Samnite remains. Among other antiquities is a subterranean aqueduct. The town, much injured in 1805 by an earthquake, is the seat of a bishop. Pop. 10,000.

Isfahan, improperly ISPAHÂN, a famous city of Persia, capital of the province of Isfahân, and formerly capital of the entire country, is situated on the Zende River, in an extensive and fertile plain, 226 miles S. of Tehran. The place, though fallen from former glories, retains much of its one-time splendour. Here is the famous Meidan-i-Shah (Royal Square), with a building of special beauty on each side—on the north the Nakkara Khaneh (Drum Tower), on the south the Musjid-i-Shah (Royal Mosque of Isfahân), on the east the mosque of Sheikh Lutfullah (the mosque of the chief priest of Isfahân), on the west the Ali Kapi (Gate of Sanctuary), behind which lies the Chehal Sittun (the Hall of the Forty Pillars), once the open throne-room of the palace. The river, here 600 feet wide, is crossed by five noble bridges, one of these, the Ali Verdi Khan, being among the world's finest structures of the kind; by it Isfahân is linked to the decayed Armenian suburb of Julfa. Isfahân is the religious centre of Persia and of the Shiite world. Commercially it continues an important city, and is the seat also of extensive manufactures, including all sorts of woven fabrics,

from rich gold brocades and figured velvets to common calicoes. Trinkets and ornamental goods in great variety, with firearms, sword-blades, glass, and earthenware, are also manufactured. Pop. estimated at 80,000.

Isfahân was a trading town of importance, and the capital of Iraq, under the khalifs of Bagdad. It was taken by Timûr in 1387, when 70,000 of the inhabitants are said to have been massacred. During the 17th century, under Shah-Abbas the Great, it became the capital of Persia, and reached the climax of its prosperity. Its walls were then 24 miles in circuit, and it is said to have had between 600,000 and 1,000,000 inhabitants. It was then the emporium of the Asiatic world; the merchandise of all nations enriched its bazaars, and ambassadors from Europe and the East crowded its court. In 1722 it was devastated by the Afghans, and some time afterwards the seat of government was transferred to Tehran (q.v.). During the Great War it was entered (March 1916) by the Russians.

Ishmael, the son of Abraham, by Hagar, the Egyptian handmaid of his wife Sarah. In the story of his life given in Genesis he was driven at fifteen from his father's house along with his mother, and grew up to manhood in the southern wilderness a famous archer. He became the progenitor of a great nation, and the character of the Arabs was supposed to have been foretold in Gen. xvi. 12. Mohammed asserted his descent from Ishmael, and the Mohammedan doctors declare that Ishmael, and not Isaac, was offered up in sacrifice—transferring the scene of this act from Moriah in Palestine to Mount Arafat near Mecca.

Ishmail. See ISMAILIS, SHÎTES.

Ish'peming, a city of Michigan, 15 miles W. of Marquette, on Lake Superior, and 392 miles N. of Chicago by rail. Large quantities of iron ore (a red hæmatite) are quarried close by, and the town possesses foundries, blast-furnaces, &c. Many of the miners are Scandinavians. Pop. 10,500.

Ishtar. See ASTARTE.

Isidore of Seville (ISIDORUS HISPALENSIS), encyclopædist and historian, was one of the most distinguished ecclesiastics at the beginning of the 7th century. He was born most probably about 560, either at Seville or at Carthage, where his father, Severianus, was prefect, and he became Archbishop of Seville about the year 590. The episcopate of Isidore is rendered notable by the two half-ecclesiastical, half-civil councils at Seville in 618 or 619 and at Toledo in 633, which were held under his presidency, and the canons of which may almost be said to have formed the basis of the constitutional law of the Spanish kingdoms, both for church and for state, down to the great constitutional changes of the 15th century. He also collected with the same object all the decrees of councils and other church laws anterior to his time. Outside these activities Isidore was a voluminous and learned writer in a Latin ornate rather than pure. His writings include *Etymologies* or *Origins*, one of the capital works of the Middle Ages, treating of the whole circle of the sciences, and showing wide reading in the Greek and Latin classics; *Libri Differentiarum sive de proprietate sermonum*; *Proemia in Libros Vet. et Nov. Test.*; *Questiones tam de Nov. quam de Vet. Test.*; *De Fide Catholica contra Judæos*; *Sententiarum Libri iii.*; *De Ecclesiasticis officiis*; *Synonyma de lamentatione animæ peccatricis*; *Regula Monachorum*; *De Natura Rerum liber*; *Chronicon*; *Historia de regibus Gothorum, Wandalorum, et Suevorum*; and *De Viris illustribus liber*. He died in 636. His personal character stands high for its simplicity and goodness. At the eighth Council of Toledo in 653 the epithet *Egregius*

was applied to him, and later Pope Benedict XIV. permitted the office of St Isidore to be recited in the 'universal church with the antiphon 'O doctor optime,' and the gospel 'Vos estis sal terræ.'

See work by Brehaut (New York, 1912). An edition by Anspach is expected. The standard edition of Isidore is that of Arevalo (7 vols. 4to, Romæ, 1797-1803), reprinted by the Abbé Migne in his *Patrologia Latina* (lxxxi.-lxxxiv.), together with the *Collectio Canonum* ascribed to Isidore. Vols. lxxxv.-lxxxvi. of the latter also contain the *Liturgia Mozarabica secundum Regulam Beati Isidori*.

Isidorian Decretals. See CANON LAW.

Isinglass (supposed to be derived from the German *Hausenblase*, 'bladder of the sturgeon'), the *Ichthyocolle* (*ichthys*, 'a fish'; *kolla*, 'glue') of the classical and scientific writers, was formerly obtained only from the common sturgeon, and consisted of the dried air-bladder of the animal. The necessities of modern commerce have, however, led to the discovery that the same part in many other fishes forms good isinglass; and instead of Russia, as formerly, being almost the only producing country, large quantities are now got from Venezuela, Brazil, the West and East Indies, India, Malacca, and Cochin-China. Its principal use is in the fining of beer, wine, and other liquids. It is also used in making confectionery, invalids' food, Indian ink, and sticking-plaster. Isinglass is not Gelatine (q.v.), but a good gelatine-yielding tissue, its value being enhanced by the ease with which it is abstracted. Unopened bladders are sold as 'pipe' or 'tongue,' or if in small pieces 'cake' or 'purse,' small, thick pieces as 'lump.' Opened bladders go by the name of 'leaf' or 'honeycomb'; folded isinglass from Russia is called 'book.'

Isis, the name applied by Leland, Camden, &c., and in the form *Ysa* by Higden (14th century), to the upper part of the river Thames (q.v.). For a long discussion of the origin of the name—a classicised form perhaps of the Celtic *uisge*, 'water'—see *Notes and Queries* for 1852-84.

Isis, an Egyptian goddess. The deities of ancient Egypt might be male or female, but in neither case could the Egyptian worshipper conceive a deity as existing in isolation: to every deity of either sex there must be a counterpart of the other sex. It was to this notion that the goddess Isis owed her origin; she was the counterpart of Osiris (q.v.), and this fact is expressed in the statement that she was at once wife and sister of Osiris. But in all such cases the counterpart remained a much less important personage than the original deity, whether male or female. The mythological functions of Isis accordingly will be found to be subordinated, at any rate in their oldest forms, to the myth of Osiris. In the next place, as the child is the reproduction of its parents, for the father lives again in his children, the son was to the Egyptian in a way identical with the father, and when, as in the case of the gods, the mother was but the counterpart of the father, the identity of the child with the parents was yet more complete. In other words, as a child is impossible without parents, so it is impossible for a father to exist without a child of which he is the father. Hence we find that the deities of ancient Egypt are grouped in triads or trinities. Father, mother, and child cannot be conceived except in relation to each other (the terms are correlative); yet, though identical and inseparable, they are nevertheless distinct. The deity who completed the triad in the case of Osiris and Isis was their son Horus. In order to understand the position occupied by this triad in the circle of ancient Egyptian deities it is necessary to premise that Egypt was no exception to the laws which

govern the growth of all political communities. All states which are larger than mere city states have become larger by the amalgamation or *synoikismos* of smaller unities. The smaller states out of which Egypt as a political whole was formed still continued after the political unification of the country by Menes to exist as administrative districts, even when Egypt became part of the Roman empire, just as the boundaries of a modern English county in many cases represent the frontiers of ancient states. In Egypt these divisions are generally known under their Greek name as 'nomes.' Each nome, while yet an independent state, possessed its own local deities. When, however, they were brought under one government a pantheon was necessarily formed, and the order of precedence amongst the various local deities arranged. Practically, however, each nome continued to regard its own deity or trinity as really the supreme god, unless it could succeed in identifying its own deity with some other member of the national hierarchy. This explains on the one hand the statement of Herodotus (ii. 42), that no gods were worshipped universally in Egypt except Osiris and Isis, and on the other hand it enables us to understand how it comes about that Isis was worshipped as Mut at Thebes, as Sekhet at Bubastis, and as Hathor or Athor at Dendera, as Sothis, the dog-star, and as the planet Venus. It also explains why Osiris, originally the local deity of Abydos, came to be universally worshipped throughout Egypt. Osiris undoubtedly owed his elevation in the Egyptian pantheon to the fact that he was identified with Ra, the sun or sun-god. In chapter 17 of the *Book of the Dead* this identification is expressed in the explicit terms, 'Ra, the soul of Osiris, and Osiris, the soul of Ra.'

We may now proceed to the mythological functions of Isis. As being the counterpart, the sister of Osiris, she was the child of the same parents as her brother and husband—of Seb (or, as some transliterate it, Qeb), the earth, and Nut, the sky. The beneficent course of the sun across the sky is terminated by his murder at the hands of his brother Set. But though the sun dies to-night, to-morrow there lives another sun, who is different and yet the same, as the child is different from and yet the same as his father. This is Horus, who avenges the death of his father Osiris. Within the limits of this myth place was found for Isis as the faithful wife of Osiris, who recovered the body of her murdered husband, after it had been flung into the Nile by Set. Having concealed the body, Isis fled to her son Horus, and during her absence Set found the body and cut it into fourteen pieces, which he scattered. These Isis collected and buried in a stately tomb. The question at once presents itself, what was the original meaning of the mythological functions ascribed to Isis in the myth of Osiris? And we may conjecture that the answer is to be sought in the original local character of Egyptian deities, in the process of identification, or 'syncretism,' and in the ritual which grew out of it. Horus was originally the local god of Edfu; he may have been a solar deity, at any rate he came to be regarded as the same, yet not the same, as the local solar deity of Abydos, Osiris. He was interpreted as the son of Osiris. But Horus was in conflict with Set; obviously, therefore, it must have been as the avenger of his father, Osiris, that Horus engaged in conflict with Set, though before Horus was brought into connection with Osiris no such story existed. Again, Horus, before he was identified as the son of Osiris, had a mother of his own, Hathor, the local deity of Dendera. By what process Horus, the god of Edfu, had come to be regarded as connected with the goddess of Dendera we do not know. But the connection was expressed in ritual by a religious procession from Dendera

to Edfu. Accordingly, when Horus became the son of Osiris, and Athor in consequence was identified with Isis, the procession in which the image of Athor—i.e. Isis—visited Horus at Edfu required a mythological explanation. It was provided by the invention of the myth of Isis' flight to Horus after the death of Osiris. The dismemberment of Osiris and the collection of the members by Isis is apparently an invention to account for the phallic ceremonies, which survive to the present day in Egypt. From this analysis of the myth of Isis and Osiris, it becomes apparent that the deities of ancient Egypt were not originally conceived in triads; but that, on the contrary, the trinity of the god was a later doctrine designed to explain the syncretism which resulted from the amalgamation of the various nomes and their deities. There is yet another mythological function ascribed to Isis which requires mention and explanation: she rocks the cradle of the infant Nile. To the Egyptian the conflict between the sun and the powers of darkness, in the heaven above, may have had its parallel on the earth beneath in the perennial conflict between the beneficent Nile with the sands of the desert. At anyrate, Osiris had the Nile as well as the sun for his emblem; and by a not unnatural confusion between Osiris and Horus, for Horus is Osiris in his youth, Isis was regarded as tending the infant Nile. Finally, we may dismiss Isis in Egypt by adding that she as Neith was regarded as the patron goddess of women, and presided over child-birth.

But we have yet to trace the fortunes of Isis in Greece and in Rome. As early as Herodotus (ii. 156) she was taken to be the same as the Greek Demeter—for no other reason apparently than that Demeter, like Isis, suffered a great loss. Only, it was her daughter, not her husband, that Demeter lost. This was, however, a trifle to stand in the way of a Greek resolved to identify his mythology with that of the oldest, the wisest, and most religious of mankind. After the time of Herodotus—probably, indeed, not until post-classical Greek times—on the ground that the wife of the sun must be the moon, Isis became a moon-goddess, and was identified by the Greeks with their moon-goddess Io. Again, as Athor, Isis was imagined to be the same as the Semitic Astarte and the Greek Aphrodite. When the attributes and powers of all these goddesses were ascribed by the (post-classical) Greeks to Isis it is easy to understand that in the Orphic mysteries Isis was the chief and most mysterious of all goddesses. Nor have we any difficulty in recognising that the Pans and Satyrs and the nursing of Astarte's children, &c. which appear in Greek accounts of Isis are borrowed from myths that really belong to Demeter, and are not Egyptian at all. Our two chief Greek authorities, Diodorus Siculus and Plutarch (*De Isid. et Osir.*), draw mainly upon one Hecataeus, of the time of Alexander; and we may say generally that it is impossible to trace Isis as a figure in Greek mythology farther back than the age of Alexander.

It is in the Roman empire that Isis becomes a mythological figure of importance outside Egypt. The process of syncretism was carried further in her case than in that of any other deity. Every function ever attributed to any deity whatever was transferred to her, and the result is best stated in the words of the mysterious goddess herself to the Golden Ass of Apuleius (*Met.* xi. 241): 'I am the universal mother nature, mistress of all elements, first-born of the ages, supreme of goddesses, queen of names, ruler of the gods, sole manifestation of all gods and goddesses, whose glance makes awful silence in the shining heights of heaven, in the depths of the sea, and of the world beneath, whose unchanging being is worshipped under many forms, with many rites, and under various names, as

mother of the gods, as the Cecropian Minerva, Paphian Venus, Dictynnian Diana, Stygian Proserpina, the ancient goddess Ceres, as Juno, Bellona, Hecate, Rhamnusia—but my true name is Queen Isis.' To this we may add the inscription mentioned by Proclus: 'I am that which is, has been, and shall be. My veil no one has lifted. The fruit I bore was the Sun.'

Iskanderoun. See SCANDEROON.

Isla, JOSÉ FRANCISCO DE, was born in 1703 at Vidanes, in north-western Spain. Early in life he joined the Jesuits, for some years was lecturer in philosophy and theology at Segovia, Santiago, and Pamplona, and became famous as a preacher, but still more as a humorist and satirist by his writings, especially his novel of *Friar Gerund*. Except Cervantes and Quevedo no man had a larger share of that peculiar grave humour which is one of the special products of Spain, and with him it seems to have been almost irrepressible. Even in *Youth Triumphant*, an account of a masque performed by the students of his own order at Salamanca in 1727, in honour of the canonisation of two young Jesuits, he could not altogether control his propensity to ridicule. The *Letters of Juan de la Encina*, written in 1732, on a pamphlet by a quack doctor at Segovia who had given him offence, are a good example of his style, but a more characteristic one is the *Dia Grande de Navarra*, a description of the ceremonial at Pamplona on the accession of Ferdinand VI. in 1746, which he wrote at the request of the local authorities. It is, in fact, an adroit caricature of the grandiloquence, pomposity, and inflated phrase usual on such occasions, but his artful flattery of provincial vanity and official self-importance blinded the eyes of the good Pamplonese, and they passed a vote of thanks to him, which he appealed to with an admirable assumption of injured innocence when the wits of Madrid charged him with the joke. He had a hearty contempt for shams and pretences of all sorts. *Friar Gerund* was aimed at the charlatanism of the popular preachers of the day, especially the preaching friars. The decline of culture produced uncritical audiences, and these again swarms of preachers who tried to get credit with the crowd for originality by tricks, mannerisms, and clap-trap. Isla's model, as he owned in his preface, was *Don Quixote*; what Cervantes had done with the sham chivalry and sentiment of the romances, he strove to do with the vulgar buffoneries of the pulpit, and he was almost equally successful. The first volume came out at Madrid in 1758, and in three days the whole edition of 1500 was sold off. From the king down everybody was delighted with it—everybody, that is, except the friars, for 'Fray Gerundio' at once became a nickname, and their congregations, they found, laughed at instead of with them. But the friars were a power, and at their instance the Inquisition stopped the publication of the book. A clandestine edition of vol. ii., with the imprint of Campazas, as well as a reprint of vol. i., came out in 1770, and another in 1787, but none with a license until 1813. Isla was struck down with paralysis in 1767 as he was obeying the edict expelling the Jesuits, but he insisted on sharing the lot of his comrades, and betook himself to Bologna, where he lived, cheerful and uncomplaining, in poverty and ill-health, until 2d Nov. 1781. A little before his death he wrote his translation of

Gil Blas. A friend had urged him to assert their country's claim to a book that, as the French themselves acknowledged, had been stolen from Spain, but he objected that he was not David enough to attack such a Goliath as Le Sage, and that he had never read *Gil Blas*. But afterwards, having nothing to do, he took it up and translated it, and further amused himself with a preface in which he humoured his friend's patriotic idea in his own grave way, by a circumstantial story in the style of *Gerundio* and the *Dia Grande*, of how Le Sage (who never was in Spain), being in the suite of the French ambassador at Madrid, met a certain Andalusian advocate who gave him the MS. of the novel. On his title-page he put, 'Stolen from Spain, and restored to its country and native language by a jealous Spaniard who will not allow his nation to be made game of;' words which sufficiently indicate his drift; but his gravity imposed upon the Comte de Neuchâteau of the French Academy, and provoked a serious refutation in 1818, to which Llorente replied in 1820; and the controversy, having that element of paradox which gives vitality to argument, still maintains a fitful existence. See LE SAGE.

The best edition of Isla's works is that in vol. xv. of the *Biblioteca de Autores Españoles*, giving *Fray Gerundio*, the *Cartas de Juan de la Encina*, the *Dia Grande de Navarra*, and a full collection of his delightful letters, but omitting his sermons and translations. The English translation of *Friar Gerund* (1772), by Dr Warner (some say Dr Nugent), is somewhat abridged and a little vulgar in its attempts at the dialect of the Campos rustics, but on the whole pretty faithful.

Isla de Pinos. See PINOS, ISLA DE.

Islām, or **ESLĀM** (Arab.), the proper name of the Mohammedan religion; designating complete and entire submission of body and soul to God, his will and his service, as well as to all those articles of faith, commands, and ordinances revealed to and ordained by Mohamied. Generically the term signifies the whole Mohammedan world. See MOHAMMEDANISM.

Islamabad. See CHITTAGONG.

Island (O.E. *īgland*; the *s* crept in through confusion with *isle*), land surrounded by water. The larger masses of land surrounded by water, or parts of them, are Continents (q.v.), and the term island is usually restricted to the smaller. Since Australia has an area of over 3,000,000 sq. m., and (omitting the Arctic island or icebound archipelago of Greenland), New Guinea, the next island in size, has only 312,000 sq. m., the distinction drawn between continents and islands in the restricted sense is more than verbal. There are few large islands. Borneo, indeed, is little inferior in size to New Guinea; but Madagascar and Sumatra are the only others with an area greater than 100,000 sq. m. Great Britain and Honshū (the main island of Japan) rank next, the former being fifth in order of size if New Guinea is taken as first. The following table shows the relative mainland area of the largest islands, excluding various Arctic islands or icebound archipelagoes, as Baffin Land, Victoria Island, &c.

Islands.	Area in sq. m.	Islands.	Area in sq. m.
New Guinea	812,000	Mindanao	37,000
Borneo	284,000	Ireland	32,600
Madagascar	227,000	Hokkaido	30,000
Sumatra	165,000	Hayti	28,800
Great Britain	88,700	Tasmania	26,200
Honshū	86,500	Ceylon	25,500
Celebes	72,000	Sakhalin	24,600
New Zealand (S. Island) ..	56,100	Tierra del Fuego ..	18,500
Java	48,400	Vancouver	16,400
New Zealand (N. Island) ..	44,100	Formosa	14,000
Newfoundland	42,700	Kyushū	13,900
Ouba	42,000	Hainan	13,000
Luzón	40,800	Sicily	9,900
Iceland	39,800	Sardinia	9,200

Two classes of islands may be distinguished—continental and oceanic. *Continental Islands* are closely allied by the structure of their rocks to the nearest continental land, from which they are rarely far distant, although sometimes—as Madagascar—separated by depths exceeding 1000 fathoms. As a rule, continental islands lie to the south and east of the continent with which they are associated. The only exceptions are islands on the continental shelf—i.e. separated by depths less than 100 fathoms, which have been cut off from the mainland in geologically recent times. With the exception of Madagascar and New Zealand, the separation of which is unusually complete, the plants and animals of continental islands are similar to those on the adjacent continent, and from the slight differences detected the period at which separation took place has sometimes been calculated. Groups of continental islands enclosing seas stretch from the south-east peninsula of each of the northern continents towards the nearest southern continent. The Greek Archipelago points from the Balkan Peninsula towards Africa, the West Indies run from Florida and Yucatan to South America, and the Eastern Archipelago extends from the Malay Peninsula to Australia. These archipelagoes represent mountainous tracts of continent which have subsided, or else irregular portions of the submarine plateaus which are undergoing elevation.

Oceanic Islands rise abruptly from great depths and show no geological continuity with the continents. They appear above the surface either as (a) *Volcanic Islands*, usually rugged peaks or vast accumulations of lava nearly as precipitous below the surface as above, or as (b) *Coral Islands* (see CORAL). Numerous submarine mountains have been discovered in different parts of the ocean, which only require moderate elevation or the deposition of sediment or coral growth to appear on the surface as islands. The fauna and flora of oceanic islands differ widely from those of the continents, and present many features of unique interest, which have been worked out in detail by, among others, Wallace in his *Island Life*. See GEOGRAPHICAL DISTRIBUTION.

Continental islands have in historical times formed the cradles of great commercial nations, the insular position giving security, and the water border acting at once as a barrier to the less adventurous continental people and as a highway to the bolder islanders, whose closer contact with the sea makes them nations of sailors.—For Floating Islands, see that head; and for fabulous islands, see ANTILLES, ATLANTIS, AVALON, BRENDAN, ELYSIUM, HESPERIDES, &c.

Islandshire, a part of Northumberland in England, embracing the Farne Islands, together with three parishes adjoining Berwick-on-Tweed (q.v.) and portions of two others. Till 1844 it formed a detached part of Durham county.

Islay, an island of Argyllshire, 13 miles W. of Kintyre, and $\frac{1}{2}$ mile SW. of Jura, from which it is separated by the Sound of Islay. Deeply indented on the south by Loch Indal (12 by 8 miles) Islay has a maximum length and breadth of 25 $\frac{1}{2}$ and 19 miles, and an area of 246 sq. m. It contains several small fresh-water lakes, and attains a height of 1444 feet. The soil is rich, and great improvements have been effected in the way of road-making, draining, reclamation, &c. Dairy-farming, stock-raising, and whisky-distillation are leading industries; whilst slate, marble, iron, lead, and silver have been worked. In the course of the 19th century the old proprietors and the native tenantry were largely superseded. Islay has regular steamboat communication with Glasgow, and

a telegraph was established in 1871. It was the ancient seat of the Lords of the Isles. Pop. (1831) 14,982; (1921) 5743.

Isle of France. See MAURITIUS.

Isle of Man, Wight, &c. See MAN, WIGHT, &c.

Isle of Wight Disease. See BEE (*Diseases*).

Isles, LORD OF THE. See LORD OF THE ISLES.

Isleworth, a Middlesex parish, on the left bank of the Thames, 12 miles WSW. of London. At Sion House, a seat of the Duke of Northumberland, the crown was offered to Lady Jane Grey.

Islington, once a suburb, now a metropolitan borough, of London, situated 2½ miles N. of St Paul's. Pop. (1861) 155,341; (1871) 213,778; (1921) 330,028. It is remarkable for its many religious, educational, and benevolent institutions. Here also are Pentonville and Holloway prisons. The Agricultural Hall (1861), used for great national cattle and horse shows, &c., can hold 50,000 people. Islington, a parliamentary borough since 1885, returns four members.

Islip, a township (pop. 21,000) of New York, lying along the central portion of the south side of Long Island; it comprises several villages which are summer resorts, and are noted also for their clam and oyster fisheries.

Ismail, a town and river-port in the Rumanian district of Bessarabia, on the north bank of the Kilia branch of the Danube, 48 miles from its mouth. Formerly a Turkish fortress, it was taken and destroyed by Suwaroff in December 1790; came into possession of Russia in 1812; was assigned to Moldavia by the treaty of Paris, 1856, its fortifications being razed; and was transferred to Russia again by the Berlin Congress of 1878, and became Rumanian in 1918. It has an active trade in corn, cattle, fish, wool, tallow, and hides. Pop. with the adjoining Tuchkov, 32,000.

Ismail. See ISMAÏLIS, SHÏTES.

Ismalia, a town on Lake Timsah, through which the Suez Canal passes. It stands on the railway from Cairo to Suez and on the Sweet Water Canal. During the construction of the canal it was the headquarters of the work, having been founded in 1863. Pop. 11,000.

Ismailis, a Mohammedan sect. Like the rest of the Shîah, or party of Ali, they held that the dignity of Imâm, or head of the true faith, was inherent in the house of the Prophet and the line of Ali, the Prophet's cousin, son-in-law, and chosen lieutenant. They arose in Syria and Persia, taking their name from one Ishmail or Ismâil, whom they regarded as the seventh and last of the Imâms, and who lived about 770 A.D. But the sect acquired its importance a century later from Abdallah al Kaddah, a Persian of Susiana, and son of Maimim. He was an oculist, a scholar, and an able juggler. The Ismailis had then no visible Imâm; indeed the Shîah lost its twelfth and last Imâm in the mysterious disappearance of Mohammed in 879 A.D. The idea of a 'Hidden Imâm,' destined to appear for the reformation of religion and of the world, thus became necessary for its existence. To undermine the whole empire, to prepare a great revolution and overthrow Islam was Abdallah's desire. His instrument was the faith in a 'Hidden Imâm,' or 'Mahdi,' 'Guided or Inspired One,' styled by Abdallah the seventh prophet, Mohammed having been the sixth. His many widely-spread dais or missionaries taught their converts that this coming deliverer had opened up the true and mystic meaning of the Koran. The teaching of all previous prophets was abrogated by him. Converts passing through their nine stages of instruction learned to deny all positive religion. Prayers, tithes, pil-

grimages, legal purity, and other religious observances were shown to have meaning and use for only the blinded crowd. A Demiurgus was declared to be the world's maker. The resurrection, the end of the world, final judgment, and rewards and punishments were mere allegories. The universe was eternal. Finally, belief was made absolutely free. Mohammed, the Chief, Hidden Imâm, Mahdi, or Seventh Prophet, son of Ismail, was, after all, not to appear but in his doctrine taught by his disciples and apostles; and the duty of all believers was to bring the world's sovereignty into the hands of these. Abdallah's son, Ahmed, succeeded him as Grand Master of the Ismailian Society. In his time a Babylonian peasant, Hamdan Karmat, joined it, became a missionary, a leader, and at length about 891 proclaimed a communistic system. For two centuries the Karmathians were the scourge of Islam and the East. An Ismailian missionary among the Berbers of Constantine called the people to arms in Ali's name. Obeidallah, a descendant of Abdallah al Kaddah, and Grand Master of the Ismailian Society, was put at the head of the revolution, before which the Aghlabite (809) and the Edrisite powers quickly fell; and, calling himself a scion of Ali, by Fatima the Prophet's daughter, was declared Khalif and Mahdi. The rise of his dynasty, which is called the Fatimite, is the most remarkable example in history of the power of religious enthusiasm led by conscious imposture. Egypt (970) and Syria were added to its empire. The Karmathians recognised it and paid it tribute. Miserably decayed, it was supplanted in Egypt by Saladin in 1171. See also MAHDI, SHÏTES.

Ismid. See NICOMEDIA.

Isobars. See METEOROLOGY.

Isochronism (Gr. *isos*, 'equal;' *chronos*, 'time'). A pendulum is isochronous when its vibrations are performed in equal times, whether these vibrations be large or small; but it can only possess this property by being constrained to move in a cycloidal arc. See CYCLOID.

Isocrates, the Athenian, who was born 436 B.C. and died 338 B.C., represents the perfection of 'epideictic' oratory—i.e. oratory in which form and literary finish count for everything, and matter for very little. Oratory, as a department of literature, was in Athens the outcome of that growth of litigiousness and development of the law-courts which characterised Athens from about the beginning of the Peloponnesian wars. The consequent necessity under which every Athenian was of being able to defend himself in a court of law first fostered the rise of a class of men—the Sophists—who professed to teach the art of argument, even to the extent of making the worse appear the better cause; and next, as the literary taste of Athenian juries increased, fostered the rise of a class who professed to teach the art of literary form, and who taught by example rather than precept. Hence 'epideictic' oratory, 'show-speeches.' Such teachers of rhetoric have existed in other countries, but at no place and in no age have they reached the artistic excellence of Isocrates. This is partly due to the fact that, owing to the peculiar circumstances just explained, teachers of rhetoric in Athens at this time could gain the ear of the public, whilst elsewhere and at other times the teacher's audience has consisted of his pupils, and he has lacked the stimulus and the corrective of competent criticism. But though the hour had come, it might have sounded in vain had not the man been there. A brief summary of Isocrates' life will show that nature had designed him for his work. If his speeches are deficient in practicality to an extent

that has irritated Niebuhr for instance, it is because Isocrates was himself so utterly unpractical. The son of a prosperous flute-maker, Isocrates received an excellent education, and in his youth heard the show-speeches made at Athens by the earliest epideictic orator, Gorgias. He also listened to the lectures of the philosopher Prodicus, and joined the circle of Socrates. But he only coquetted with philosophy, and though in the *Phædrus* of Plato Socrates expresses the highest expectations of him, Isocrates abandoned philosophy. He then took to speech-writing as a profession, but he had none of the talents required in the composition of speeches having such a practical object as that of winning a case in a law-court. After trying his hand at six such speeches (402-393 B.C.) he abandoned logography. If he failed in writing practical speeches to be delivered by others, he was still less adapted by nature to deliver his own speeches himself and follow a political career; his voice was too feeble, and he was much too nervous. Other people since Isocrates having failed in other pursuits have betaken themselves to schoolmastering, but Isocrates deserves the credit of having been the first to discover this resource. About 390 B.C. he set up as a teacher of oratory, though he did indeed profess, in the speech which served as his prospectus (*Against the Sophists*), to give a general practical education. In his prospectus he was careful to distinguish himself from such shallow pretenders as the Sophists on the one hand, and on the other from such unpractical teachers as philosophers. This sample of his skill as an artist in words, though it drew from Plato (*Euthydemus*, 304, D) some contemptuous animadversions on the little knowledge of certain persons who cultivate the domain intermediate between philosophy and politics, succeeded in drawing to him pupils who subsequently became distinguished, statesmen such as Timotheus and Laodamas, historians such as Ephorus and Theopompus, orators such as Isæus, Lycurgus, Æschines, and Hyperides. Pupils paid him 1000 drachmæ, and were put by him through a course of three or four years' duration. He himself composed model speeches for them, such as the *Panegyricus* (about 380 B.C.) and the *Platæicus* (373), and corrected the oratorical exercises composed by them. But he also wrote speeches intended to be practical: one of them, the *Archidamus* (365 B.C.), may actually have been composed for and delivered by the Spartan king, Archidamus, but the majority, for instance the *Symmachicus* (357 or 355 B.C.), the *Areopagiticus* (about 354 B.C.), the *Panathenæicus* (342-339), and the letters to Philip of Macedonia, were not designed to be delivered but to be circulated and read—they are in fact the earliest political pamphlets known. As a politician, or rather a would-be politician, Isocrates has only one idea, and that an utterly impracticable one—to unite all Greeks together in a joint attack upon the common foe, Persia. The practical commentary on this ridiculous Pan-Hellenistic panacea was the destruction of Greek freedom on the field of Chæronea by the very Philip to whom Isocrates looked to make his nostrum effective. 'That dishonest victory,' in the words of Milton, 'killed with report that old man eloquent.' Isocrates did indeed die shortly after the news of the battle at the age of ninety-eight, but it may be doubted whether it was the news that killed the schoolmaster. Unpractical Isocrates certainly was. Alexander conquered Asia in less time than it took Isocrates to write a single speech (the *Panegyricus*). But it was this very characteristic which made the oratory of Isocrates what it is. And Milton's tribute to him may serve to remind us that, in the opinion of all competent judges, for melody, artistic merit, perfection of form

and literary finish, Isocrates stands unrivalled. He has of course the defects of his qualities. His work may be finished, but it is undeniably laboured. He may have melody, but it is apt to become monotonous. He is always smooth, even where he ought to be stormy. Such perfection of form as he attained could only be produced by an artist who was willing to sacrifice everything else to it, and Isocrates by nature did readily incline to do so. A few obvious generalities and a few moral sentiments were all that he required in the way of matter for a speech—indeed for many speeches. The result is that having read one of his speeches you have read all. The truths of morality are indeed eternal, but they will not bear eternal repetition. Had but one of his speeches survived, his poverty of thought would never have been discovered, but fate with cruel kindness has preserved nearly everything he ever wrote. But if Isocrates is too beautiful to be absolutely perfect himself, we must not forget that to appreciate his services to Greek literature we must not consider him apart from the history of Greek oratory. He demonstrated once and for all, and at precisely the time when the demonstration was necessary, that prose as well as poetry may have an artistic beauty, may have rhythm, flow, and melody of its own. It was worth a lifetime's labour to effect this; and if it was only in Demosthenes that this outward beauty came to be wedded with nobler and with manlier qualities, let us remember that it were as vain to expect the fruit without the blossom as to imagine that we could have had Demosthenes without Isocrates.

The first edition was printed at Milan in 1493. The best edition of the text is that in the Teubner series. There are excellent English notes on the *Demonicus* and *Panegyricus* by J. E. Sandys, German notes by Rauchenstein on the latter and the *Areopagiticus*. Vol. i. of an English translation by Freese appeared in 1894.

Isodynamic, Isoclinic, and Isogonic

Lines, or lines of equal force, equal inclination, and equal declination, are three systems of lines, which being laid down on maps represent the magnetism of the globe as exhibited at the earth's surface in three classes of phenomena, the varying intensity of the force, the varying dip or inclination of the needle, and its varying declination from the true meridian. See MAGNETISM (TERRESTRIAL).

Isoetes, a genus of pteridophytes, mostly aquatic, forming an order (Isoetaceæ) generally classed as Lycopodiaceæ. The stem grows in thickness by a cambium layer. The awl-shaped leaves sheathe the stem, and bear sporangia in a pit near the base—microsporangia in the outer, megasporangia in the inner, and generally none in the innermost. The spores are released by decay of the sporangium-wall. Development is similar to that of Selaginella. Quillwort and another species are British.

Isola Bella. See BORROMEAN ISLANDS.

Isola Grossa, ISOLA LUNGA, or DUGI, a long, narrow island, 27 miles by 1 to 2½, running parallel to the coast of Dalmatia, over against Zara. It belongs to Yugoslavia, and has splendid natural harbours. Area, 54 sq. m.

Isola Madre. See BORROMEAN ISLANDS.

Isomerism (from the Greek word *isomērēs*, 'composed of equal parts'), the relation between chemical compounds which are identical in their ultimate or percentage composition, but present differences in their chemical properties. Isomeric compounds, or *isomerides*, are divisible into metameric compounds, or *metamerides*, and polymeric compounds, or *polymerides*.

In all metameric compounds the molecular weight is the same, while in all polymeric com-

pounds the molecular weights are simple multiples of the molecular weight of the lowest member of the group. As an illustration of metamerides, propionic acid, $C_2H_5 \cdot CO \cdot OH$, acetate of methyl, $CH_3 \cdot CO \cdot OCH_3$, and formic ether, $H \cdot CO \cdot OC_2H_5$, may be taken. Their rational formulæ, which express their probable constitution, are perfectly distinct, yet they all have the same percentage composition, the same empirical formula, $C_3H_6O_2$, and the same molecular weight (74).

As an illustration of polymerides, the hydrocarbons homologous with olefiant gas may be taken. Olefiant gas is represented by the formula C_2H_4 , propylene by C_3H_6 , butylene by C_4H_8 , amylene by C_5H_{10} . These substances have the same percentage composition, but different molecular weights.

The carbohydrates, which are represented by the general formula $C_xH_{2x}O_x$, present well-marked examples of isomerism. Thus, cellulose, $C_6H_{10}O_5$, starch, $C_6H_{10}O_5$, and gum, $C_6H_{10}O_5$, are metameric; while grape-sugar, $C_6H_{12}O_6$, possesses the same percentage composition, but twice as high a molecular weight, as lactic acid, $C_3H_6O_3$, and the same percentage composition, but three times as high a molecular weight, as acetic acid, $C_2H_4O_2$; hence the three last-named substances are polymeric.

The most recent researches have brought to light the existence of several special varieties of isomerism. A *tautomeric* body is one in which the reaction to some reagents is as if certain hydrogen atoms were in one place in the molecule, while to others it is as if the hydrogen occupied a different position; and a *tautomeric* body may be *desmomic* when it can be prepared in recognisably different forms, differing from one another in the position of these wandering hydrogens. *Allotomeric* bodies have a similar chemical structure, but the geometrical symmetry is different, as in the following case (in which the symbol X stands for the group $\cdot CO \cdot OH$):

The question of geometrically symmetrical or asymmetrical arrangement of atoms in a molecule has become, in the hands of Wislicenus and others, one of considerable importance in reference to isomerism. Quite possibly the allotropic modifications of some of the elements (see ALLOTROPY) are really isomeric differences of arrangement of the atoms within the molecule (q.v.). See also AROMATIC SERIES and CHEMISTRY.

Isomorphism (derived from the Greek words *isos*, 'equal,' and *morphē*, 'form') strictly signifies similarity of form, but it is now restricted by chemists to those substances which are not only similar in their crystalline form, but are also analogous in their chemical composition. The diamond, C, magnetic oxide of iron, $FeO \cdot Fe_2O_3$, and potash-alum, $K_2SO_4 \cdot Al_2(SO_4)_3 \cdot 24H_2O$, all crystallise in octahedra, but there is obviously no analogy in the chemical composition of these substances; on the other hand, the spinelle ruby, $MgO \cdot Al_2O_3$, magnetic oxide of iron, $FeO \cdot Fe_2O_3$, and chrome ore, $FeO \cdot Cr_2O_3$, not only crystallise in octahedra, but (as their formulæ show) are also analogous in their chemical composition. Hence the members of the latter group, not the former, are truly isomorphous in the restricted sense. As further examples we may quote the elements arsenic, antimony, and tellurium; the chloride, bromide, iodide, and fluoride of potassium; the sesquioxides of aluminium, iron, chromium, and manganese; and for additional lists refer to Miller's *Chemical Physics*. In most cases, as Mitscherlich

(to whom we owe most of our knowledge of this subject) showed, the chemical composition of substances that correspond in form is analogous; and that chemist further endeavoured to prove that crystalline form is independent of the chemical nature of the atoms, and that it is determined solely by their grouping and relative positions; the same number of atoms combined in the same way always producing, according to him, the same crystalline form. The coincidence of similarity in crystalline form with similarity in atomic arrangement is the most important generalisation yet arrived at in the science of crystallography; and in chemistry it has been of essential service in facilitating the classification of compounds, and to some extent in determining the combining numbers or atomic weights of the elementary bodies.

Isonzo (Slov. *Soča*; anc. *Sontius*), a river of Italy, rises in the Julian Alps, flows tortuously southwards, and, after a course of some 85 miles, enters the Gulf of Trieste by two mouths, the western really losing itself in the marshes, the eastern, canalised below Sagrado, forming on its way to the sea the port of Monfalcone. The river, locally celebrated for its trout, is turned to account in irrigation and in the production of electrical power. On the Isonzo in 238 the advance of the emperor Maximin upon Aquileia was temporarily stayed, and in 489 Odoacer was defeated by Theodoric. During the Great War, previous to the Italian repulse to the Piave (October–November 1917), the Isonzo, then in Austrian frontier territory, was Austria's line of defence against Italy, and as such was the scene of many battles.

Iso-poda (Gr., 'equal-footed'), an order of higher Crustaceans, which agree with Amphipoda (q.v.) in having sessile eyes, uniramous thoracic limbs at all stages, and no carapace; and differ in being flattened dorso-ventrally, not laterally, in the posterior position of the heart, and in having the breathing organs on the abdominal, not thoracic limbs. They are mostly marine; a few occur in fresh water; the wood-lice are terrestrial. The majority feed on decaying organic matter, but not a few are parasitic, e.g. Cymothoidæ, Bopyridæ, and Cryptoniscidæ. The terrestrial wood-lice include Oniscus, Porcellio, Armadillidium, and other genera; on the shore are found forms like Ligia; a common freshwater species is *Asellus aquaticus*; the 'gribble' (Limnoria) bores into wharf-posts and ship-sides; there are many remarkable deep-sea types, like *Bathynomus giganteus* from the Gulf of Mexico and the Indian Ocean, sometimes measuring a foot long by four inches broad. See CRUSTACEA, FISH-LOUSE, WOOD-LICE.

Isothermal Lines. See TEMPERATURE.

Isotope. It is found (Aston) that the Positive Ions (q.v.) of many elements can be separated into groups presenting the characteristic that each group corresponds to an atomic weight expressible in integral numbers if the at. wt. of oxygen be reckoned as 16.00. Thus neon presents two groups, the one corresponding to an at. wt. = 20.00, the other to an at. wt. = 22.00; but the accepted at. wt. of ordinary neon is 20.2; therefore ordinary neon consists of a mixture of 90 per cent. of a variety of neon whose at. wt. is 20 with 10 per cent. of another variety whose at. wt. is 22. These two varieties of neon are chemically indistinguishable, and cannot be chemically separated from one another, though they may be physically separated; and the two varieties are 'isotopes' of one another. Similarly, chlorine (at. wt. 35.4) is a mixture of two isotopes, of at. wt. = 35 and 37. Cases have been observed in which there are as many as seven isotopes. See Andrade, *Structure of the Atom*, pp. 89–96 (1923).

Isotropism, physical homogeneity or amor-phism; identity of elastic forces of propagation of vibration (light, heat, sound), or identity of susceptibility to magnetisation, in all directions.

Ispahân. See ISFAHÂN.

Israel, KINGDOM OF. See JEWS.

Israëls, JOSEF, genre-painter, was born at Groningen in 1824. He studied at Amsterdam under Kruseman, and in Paris under Picot and Ary Scheffer. In 1855 his 'William, Prince of Orange, opposing the Decree of the King of Spain' attracted attention in the Exposition Universelle. But historical art was foreign to his natural bent. He soon turned to scenes from humble life, and settling at Katwijk, near Leyden, he devoted himself to the portrayal of the fisher-folk, sending to the Salon of 1857 his 'Children of the Sea' and his 'Evening on the Shore.' In 1867 his celebrated 'Interior of the Orphan Asylum at Katwijk' gained for him a third-class medal and the ribbon of the Legion of Honour; and eight years later he was awarded the cross and a first-class medal. Afterwards he resided at The Hague, working indefatigably, and producing a long series of genre-pictures in oils and water-colours, presenting, usually in its pathetic aspects, the life of the humbler classes of Holland. He died 12th August 1911. At first his work was somewhat violent in colour, but gradually it became subdued, harmonious, and lovely; his management of the restricted tonality which he adopted shows the most accomplished artistic skill; and his handling is large, vigorous, and unlaboured. Among his chief pictures may be named 'Meditation' (1850), 'The Shipwrecked Mariner' (1861), 'Alone in the World' (two paintings, 1878), 'The Sewing-school at Katwijk' (1881), 'Silent Company' (1882), 'Fine Weather' (1883), 'The Struggle for Life' (1883), and 'Toddler' (1888). He is also favourably known as an etcher by 'Old Mary,' 'The Cradle,' 'The Mother,' 'The Fisherman,' 'Old Man,' and other plates (collection by Hubert, 1910), very simple, direct, and painter-like in their method. See works by Netscher (1887) and Phythian (1912); also Eisler in *The Studio* (special spring number, 1924).

Issik-kul (Kirghiz, 'warm water'), a lake in Turkestan, situated, at an elevation of 5000 feet above sea-level, between the Terskei Ala-tau range on the south and the Kungei Ala-tau on the north. It measures 112 miles long, 38 miles broad, and covers an area of 1980 sq. m. Its water is very salt, but full of fish, especially carp. It receives forty or more rivers, but its surface falls permanently at the rate of 8 or 9 inches a year.

Issoire (anc. *Issiodorum*), a town in the French department of Puy-de-Dôme, near the confluence of the Couze and Allier, 21 miles by rail SE. of Clermont-Ferrand; pop. 6000. It was treated with savage fury by the Protestants (1574) and the Roman Catholics (1577) during the religious wars after the Reformation.

Issoudun, a town in the French department of Indre, 72 miles S. of Orleans by rail, has tanneries, manufactures of parchment, cloth, &c., and quarries of lithographic stone; pop. 14,000.

Issus, anciently, a seaport on a gulf of the same name in Cilicia, Asia Minor, celebrated for the victory which Alexander the Great obtained here over Darius (333 B.C.), the camp, treasure, and family of Darius falling into his hands.

Issy, a town in the French department of Seine, half a mile SW. from Paris, possesses a seminary, a retreat for old men, a castle, and manufactures of chemicals, &c. The wide country around is used for aviation. Pop. 23,000. Here on 3d July

1815 Blücher defeated Davout. In 1870-71, during the siege of Paris by the Germans, the fort of Issy suffered severely from gun-fire.

Istakhr, or STAKHR, an ancient city of Persia, built near Persepolis (q.v.).

Istanbul. See CONSTANTINOPLE.

Isthmus, in Geography, a narrow neck of land joining two larger portions, as the Isthmus of Suez and the Isthmus of Panama. The name was often applied by the ancients without any addition to the Isthmus of Corinth, joining the Peloponnesus to continental Hellas. Here were celebrated the Isthmian Games, one of the four great national festivals of Greece (see ATHLETIC SPORTS).

Istria, a former Austrian land, forming a peninsula in the north-east corner of the Adriatic Sea, between the Gulf of Trieste and the Gulf of Fiume or Quarnero. Although a mountainous land, often swept by the sirocco and bora winds, it yields excellent olive-oil and wine. This land was lost to Austria in the Great War, subsequent possession being disputed by Italy and Yugoslavia; the treaty of Rapallo (1920) gave practically the whole of the region (area, 2000 sq. m.; pop. 343,000) to Italy.—For Dora d'Istria, see GHICA.

Itacolumite, a schistose quartzite, containing scales of mica, talc, and chlorite, which are often so arranged as to give a certain flexibility to the rock (*flexible sandstone*). In Brazil and the south-eastern states of North America itacolumite sometimes contains diamonds.

Italia Irredenta (It. *Italia irredentista*, *irredenta*, Lat. *in-redempta*, 'unredeemed Italy'), in Italian politics of the later 19th century and after, words denoting European lands neighbouring on Italy, Italian in speech, but politically joined to other countries. As originally understood, *Italia Irredenta* embraced such lands as Southern Tyrol ('the Trentino'), Görz, Trieste, Istria, Dalmatia, Ticino, Nice, Corsica, and Malta, and the incorporation of these regions into Italy became in the last quarter of the 19th century the aim of an 'Irredentist' Italian political party. Agitation in this sense was specially active from 1878 till 1882, after which date Italy's entry in the Triple Alliance into partnership with Austria, against whom up till then the real force of the movement had been directed, caused Irredentism to lose much of its power, but not to disappear. Later events proved favourable to the cause, and the outbreak of the Great War created circumstances in which the realisation of Irredentist aims became possible. The cession to her of Irredentist territories in Austria, Italy claimed as the price, first to Austria-Hungary of her maintenance of neutrality, and thereafter to the Allies of her active intervention in the war. This price, rejected by Austria-Hungary, was accepted by the Allies in the secret Pact of London (1915), and at the conclusion of hostilities was paid in the main in the treaties of St Germain (1919) and Rapallo (1920). See ITALY, WAR (GREAT). As a term, 'Irredentism' has acquired a generic as distinct from its originally specific sense, e.g. Polish, Turkish Irredentism.

Italian Architecture. This term is usually limited to the style practised by the Italian architects of the 15th, 16th, and 17th centuries, and since adopted in every country in Europe. The style originated in a revival of the ancient architecture of Rome. Although Gothic architecture had been practised in Italy during the 13th and 14th centuries, it had never been thoroughly naturalised. The Italians always showed a preference for the round arch over the pointed northern form; and even in the buildings they erected in the pointed style there is a certain

simplicity and largeness of parts indicative of a classic feeling. As early as 1350 Giovanni Pisano, in the beautiful sculpture of the pulpit in the Baptistery at Pisa, showed a return to the ancient models. Arnolfo di Cambio planned the cathedral of Florence (1290-1300), and in his design proposed a great dome (a remarkably Roman feature) over the crossing of the nave and transept. This he did not live to complete; but he prepared the way for Brunelleschi (q.v.), who went to Rome to study the ancient buildings there, at that time neglected and hardly known to the Italians themselves, and ultimately, notwithstanding great opposition, succeeded in carrying out the construction of the dome as it now stands. From this time the revival of Roman architecture went on rapidly. It was encouraged by the popes and other princes of Italy; and the invention of the printing-press soon spread a knowledge of the works of the Italian architects over Europe. At first the Roman mouldings and ornaments only were copied and applied to the existing forms. As the ancient style became better understood its general principles were gradually adopted, until at length the Modern Italian style was formed. This style may be defined as ancient Roman architecture applied to the forms and requirements of modern buildings. It has been admirably applied to domestic, but it has never been so successfully used in ecclesiastical edifices.

Library of St Mark's, Venice,
by Sansovino.

Ricardi Palace, Florence,
by Michelozzo.

The domes of the Italian churches render the interiors of these buildings very impressive, and are a feature, for the introduction of which into the west of Europe we are indebted to this style; but the façades of the churches are broken up into stories, and want the unity of a Gothic front.

Italian architecture is divided into three styles or schools, according to the places where it was practised—viz. the Florentine, Roman, and Venetian. The Florentine buildings are massive and grand in effect; they are indebted to ancient Roman art chiefly for details, the outlines being the same as those of the older buildings, designed to suit the requirements of the locality. Florence being a turbulent city, every man who had anything to lose had literally to make his house his castle. Accordingly, the basement floor is massively built with large blocks of stone, and the windows are small and plain. The Roman school naturally resembles more closely the ancient Roman buildings so numerous in that city—pilasters, arcades, &c. being freely used. In Rome the plan of including two or more stories in one *order* of columns or pilasters with their entablature, having an attic or low story above, first originated, and was afterwards extensively, but, as already explained, not successfully applied to churches.

The Venetian style is, as might be expected in a city long accustomed to elegant palaces, the most ornate and picturesque of the Italian schools. Venice is crowded with specimens of all kinds from the earliest to the latest Renaissance, and retains its individuality of style from first to last. Each story is marked by a separate tier of columns or pilasters with their entablature; the windows are arched and ornamented with columns, and the spandrels commonly filled with figures. The outline is varied in form, and is usually finished with a balustrade, broken by pedestals, and crowned with sculptured figures. It is from this most picturesque of the styles of the Italian Renaissance that the other countries of Europe derived their peculiar forms. See RENAISSANCE, ELIZABETHAN, PALLADIO.

Italy, a kingdom of Europe, comprising the central of the three great peninsulas of southern Europe (excepting the small republic of San Marino, q.v.), together with Sicily, Sardinia, and some smaller islands. Knit to the solid mass of central Europe by the Apennines, the peninsula projects south-eastward into the Mediterranean like a magnet, drawing to itself in ancient times the lordship and commerce of the whole sea, and serving as the avenue by which the culture of the East was carried into northern and western Europe. At the Strait of Otranto Italy approaches within less than 50 miles of Albania. The Alps stretch from the Gulf of Fiume to the Riviera, and almost without a break shut in the kingdom from Yugoslavia, Austria, Switzerland, and France. The peninsula itself extends from the Alps to the southernmost point of Calabria, an unnamed headland in 37° 54' 54" N. lat., or 24" farther south than Cape Spartivento. The extreme eastern point is the Cape of Otranto, 18° 30' 37" E. long., and the western Monte Tabor, 6° 33' 7" E. Its greatest length in a direct line is about 700 miles; the breadth ranges from some 400 miles in the north to about 20 between the Gulfs of Santa Eufemia and Squillace, but in most places is about 90 or 100 miles. The seaboard of the peninsula extends to over 2000 miles.

The area of Italy is 117,982 sq. m.; the population 38,710,576 (density, 328.1 per sq. m.). The area is nearly that of Great Britain and Ireland; the population somewhat in excess of that of England and Wales. Of the area, some 7350 sq. m., made up of Southern Tyrol and lands round the head of the Adriatic, came to Italy from Austria after the Great War. Continental and peninsular Italy, with the small islands embraced in its administration and excluding Zara and district isolated on the eastern Adriatic, comprises about 98,726 sq. m. At the first general census of the kingdom, in 1871, the population was 26,801,154;

in 1895 it was estimated at 30,913,670; but boundaries having altered, these figures are not comparable with those of later date.

Among the largest towns of Italy are Naples, 772,000; Milan, 719,000; Rome, 692,000; Turin, 502,000; Palermo, 394,000; Genoa, 316,000; Florence, 254,000; Catania, 252,000; Trieste (in new territories), 239,000; Bologna, 211,000; Messina, 176,000; Venice, 172,000; Leghorn, 115,000; Bari, 115,000; Padua, 112,000; Ferrara, 108,000; Taranto, 104,000; Brescia, 100,000. Zara (q.v.), with small surrounding district, came to Italy in 1920; Fiume (q.v.) in 1924. The seat of government was at Turin from 1861 to 1865, then at Florence till 1870, since which date Rome has been the capital of the kingdom.

While the population of Italy as a whole is overwhelmingly Italian, there are in various districts important Spanish (in Sardinia), Greek (Southern Italy), Albanian (Calabria, Puglie, Sicily), French (Piedmont), German (Piedmont, Venetia, Trentino), and Slav (Venetia, Istria) elements, the numbers of the last two having been greatly increased as a result of Italy's territorial acquisitions after the Great War. (A list of the pretty numerous places in the Neapolitan and Sicilian provinces where Albanian, an Italianised Modern Greek, Gallo-Italic, Provençal, and Illyrian are still in use as 'linguistic islands,' will be found in a paper contributed by Prince Lucien Bonaparte to the Philological Society, March 1890.)

In Italy a marked excess of births over deaths leads to a continuous increase in population, and the resultant phenomenon of constant emigration is one of the most striking features of Italian social and economic life. In 1913 the highest recorded figure of 872,598 emigrants was reached. In 1909-13 the yearly average was 678,960. In 1923 the figure was 395,000. The emigrants proceed to the various countries of Europe, and to those of North and South America (Argentine, United States, &c.), the proportion going to the United States previous to the passing of the immigration law of 1917 being formerly very great. Many of the emigrants return, either on the conclusion of seasonal employment, or after having spent one or two years abroad, and their savings, either brought back or sent back to Italy, are an important factor in the economic welfare of the country.

To the kingdom proper must be added Italy's colonial possessions in Africa (since 1885) and elsewhere. Eritrea (*Erythræa*, from the Greek word for 'red') extends 670 miles along the Red Sea coast, from Cape Kasar to the Straits of Bab-el-Mandeb, with an area of 45,800 sq. m. and 396,000 inhabitants, Massowah and Asmara being the chief towns. Part of the Danakil country is included; the protectorate claimed over Abyssinia by the treaty of 1889 was put an end to by the disaster of Adowa in 1896. The colony and protectorates of Italian Somaliland have an area of 140,000 sq. m. and 650,000 inhabitants. Libia Italiana, annexed from Turkey in 1911-12, has an area of 400,000 sq. m. and about 800,000 inhabitants. By treaty of 1924 Britain ceded the greater part of Jubaland to Italy; and outside Africa, by the Treaty of

Lausanne (1923), Italy obtained the island of Rhodes and the Dodecanese—area, 1000 sq. m.; pop. 100,000.

Physical Features.—The configuration of continental Italy (for the islands, see *SARDINIA* and *SICILY*) may be easily explained; in the peninsular portion it is determined mainly by the great chain of the Apennines. It is usual with geographers to divide the country into Northern, Central, and Southern Italy, the middle section generally being taken to extend between Spezia and Cape Circello on the west coast and Rimini and Monte Gargano on the east coast. This division, however, especially as regards its southern boundary, is purely arbitrary, and it will be more convenient in this article, while retaining the terms commonly in use, to describe the country under the two divisions into which physically it falls—the great plain of Northern Italy, and the generally mountainous peninsula to the south.

On the northern frontier the Alps sweep round in a mighty arc from Nice to Fiume, running out in places into Piedmont, Lombardy, the Trentino, Venice, and Istria. For the most part they rise steep and abrupt, except where their wall is pierced by long, deep valleys; and some of the loftiest peaks in the system, including Mont Blanc and Monte Rosa, belong to this mountain-girdle. The highest mountain entirely within the kingdom is Gran Paradiso (13,652 feet), the culminating point of the Graian Alps, in Piedmont. Between the Alps and the Apennines spreads the broad, fertile Lombardo-Venetian plain, a nearly level country, which differs altogether in character from the peninsula to the south, and for a long period was politically distinct from it. Most of this great alluvial tract, which fills the greater part of Northern Italy, belongs to the basin of the Po; it is irrigated by numerous streams and canals, and is one of the most fruitful and flourishing districts of Italy. The principal rivers are fed from the Alpine lakes; and the Po (q.v.), which descends from Monte Viso, on the western frontier, and, as it sweeps across the plain, receives the contributions of numerous important streams, ranks for its volume of water among the notable rivers of Europe. It is navigable for 320 out of its 420 miles, and several of its tributaries are also navigable. The Adige, which is connected with the Po by canals, is also, although much more rapid, navigable in its lower course, and so is the Brenta; the other streams that pour down through the Venetian plain are mostly mountain-torrents. The lakes of Northern Italy belong to a different class from those of the peninsula. Many of the Po's tributaries spread out at the foot of the Alps into considerable bodies of water, among which are the Lago di Garda (127 sq. m.), Lago Maggiore (81), and Como (58). These lakes are all remarkable for their depth; Maggiore is reported to have a depth of 1158 feet, Como 1358, and Garda 1916 feet. From Rimini to the Gulf of Trieste the coast is flat and marshy from the overflow of the rivers, and fringed, both north and south of the muddy delta of the Po, for long distances by lagoons. These lagoons are in general separated from the sea by only a narrow strip of sand, with openings at intervals, and contain some important harbours, such as Venice and Chioggia. On the Riviera coast, from the frontier near Nice to Spezia, the sunny, rugged mountains come close to the water's edge, the only considerable portions of level ground occurring at the mouths of valleys. The Apennines shut out this district from the rest of Northern Italy, and from their proximity there are no large streams along the coast here. The geology of the north and west of Northern Italy is that of the Alps (q.v.). In the basin

of the Po there are vast moraines left by the glaciers of the Glacial Period; and the isolated Monti Berici and Euganean Hills, in the plain north of the Adige, are of volcanic origin.

In the peninsula the Apennines are the most important feature. The chain, after stretching across from the Gulf of Genoa to the Adriatic, turns and runs down in a broad, irregular mass to the extremity of Calabria, but does not extend into the 'heel' towards Otranto. Its highest point before it makes its bend is Monte Cimone (7110 feet); but the mean elevation is only some 5200 feet, and the principal summits of the range occur in Central Italy. Here it no longer presents a continuous ridge, but is broken into mountain-masses and short ranges, marching in a roughly parallel direction, and separated by extensive upland valleys. The limestone rocks of the Apennines, rugged and cleft, fill the interior of the country with picturesque mountain-scenery, which becomes wilder as the chain stretches farther south, and in the Neapolitan highlands exhibits a savage grandeur, that is softened somewhat by the fertile 'red earth,' formed from the disintegrated limestone. In Central Italy the main chain follows the Adriatic side, and its eastern slope is the steeper; the western is less abrupt, and contains numerous valleys. The culminating peak of the Apennines is Monte Corno (9577 feet), in the great mountain-mass called Gran Sasso d'Italia. The bold promontory of Monte Gargano (once an island) does not belong to the Apennine system. The Neapolitan Apennines fill the rest of the peninsula, crossing over to the west coast, and running close upon the sea again, as in Northern Italy; but the system properly ends with Monte Pollino (7376), where the Calabrian peninsula begins; for here the limestone, except at long intervals, gives place to granite, gneiss, and crystalline schists—to reappear, however, in the mountains of Sicily, which may be looked upon as a continuation of the range (for the geology, see *APPENNINES*). On the west side of the peninsula, between the main chain and the sea, a volcanic tract extends from the isolated trachytic cone of Monte Amiata (5689), in Tuscany, to the Monti Laziali, and as far south as Vesuvius (4206), the only volcano still active. The entire Campanian plain, the Roman Campagna, and the country round Viterbo are mainly of volcanic origin; and throughout this tract are a number of small lakes occupying crater-shaped basins. The only volcanic peak east of the main chain is Monte Vulture (4364), somewhat farther north than Vesuvius. To the volcanic centres within the peninsula may be added Etna in Sicily, and Stromboli in the Lipari Islands. Tuscany is a hilly country, which seldom rises into mountains. Farther south the Roman plain, the Pontine Marshes, and the fertile Campanian plain are connected, with unimportant breaks; but on the east side of the Apennines the only plain is that of Apulia, which rises into undulating downs, and, in the peninsula to the north-east of the Gulf of Taranto, into low, barren hills of Pliocene formation. North of Apulia stretches of vine-clad hills occupy the country between the mountains and the Adriatic, until the lowlands of Northern Italy are reached.

The rivers of the peninsula present a striking contrast to those of the northern plains. Here are no such inexhaustible reservoirs as in the lakes and snowfields of the Alps, nor is the rainfall of importance save in the winter months; so that even the larger lowland rivers, except the Tiber, fall considerably in summer, and in the south what are torrents after heavy rains often in the dry season disappear altogether. The chief rivers of the peninsula flow into the Tyrrhenian Sea; but only the Tiber (for 90 miles) and, to a less extent,

the Arno (66 miles), Volturno, and Garigliano are navigable. The lakes of the peninsula are either crater-lakes, such as that of Bolsena (45 sq. m.), or occupy troughs among the mountains. To the latter class belongs Trasimeno or the Lago di Perugia (52 sq. m.); Fucino or Celano, which was a larger lake, has been drained, and is now cultivated. The coast along the Adriatic extends unbroken, except where the Gargano promontory forms the Gulf of Manfredonia; and on this side the only harbours, unless we include Ancona, are Brindisi, Barletta, and Bari. Taranto is one of the best harbours in Italy. A vast fertile plain, but infested with malaria, adjoins the gulf of that name; while nearly everywhere in Calabria the coast, though richly clothed with southern vegetation, is more or less steep, and the only port is Reggio, on the Strait of Messina. To the north are the Gulfs of Policastro, Salerno, Naples, and Gaeta, that of Naples, sheltered by the islands of Ischia and Capri, being especially well provided with harbours. In Central Italy the west coast contains several long, shallow bays, divided by promontories which have been formed by alluvial deposits connecting rocky islands with the mainland; but still farther north, along the Riviera, the steep coast presents a number of admirable harbours, such as Spezia, Genoa, and Savona.

Climate and Vegetation.—The generally warm climate of Italy is considerably modified in places by the presence of the mountain-ranges or the proximity of the sea. The plain of the Po, open to the icy winds from the Alps, and closed to those from the south, has a cold if short winter (the mean winter temperature of Turin is nearly the same as that of Shetland), while along the Riviera the temperature is as high as, and sometimes higher than, that of Rome or Naples. Throughout the peninsula the temperature is lowered by the presence of the Apennines, and some of the coldest districts of Italy are found in the Marches and in the Abruzzi uplands. Moreover, the Adriatic coast, exposed to the north-east winds, is colder than the corresponding west coast. July is in general the hottest month, but in the extreme south, August; the coldest month is January. Temperatures as high as 109° F. (in Apulia), and as low as -25° F. (on Monte Stelvio, in Lombardy) have been recorded, but over the whole country the summer mean lies between 70° and 80° F., the winter mean between 35° and 50° F. With regard to the rainfall a considerable difference is observable in the various sections of the country. In the very south there are but two seasons, a wet and a dry; whereas in Northern Italy there are two greater and two lesser rainy periods in the year, most rain falling in October and in spring, and least in winter. Over all the peninsula autumn is the wet season; but in the islands most rain falls in the winter months. The mean annual rainfall varies from about 17 to 60 inches. The lowest mean is in Foggia and on the Sardinian coast; the highest in the Julian Alps, and in Bergamo and Novara. The distribution of moisture is very unequal, even in districts near one another (the yearly mean of Venice itself is less than half that of Udine); but in general most rain falls in the mountains. Snow is common in the basin of the Po, becoming less so as we proceed south, except in the uplands, where in some districts it lies for months. The cold mistral blows in the Gulf of Genoa, and the scorching sirocco affects the coast sometimes as far north as Venice. The singular clearness of the atmosphere, enhancing the charms of buildings and of landscape, strikes every visitor; but in many districts the evil presence of malaria, from July to October especially, forms a serious drawback to the sunny climate. Indeed, some of the most fertile tracts of Italy, as

in Calabria, have for centuries lain deserted owing to this plague. The malignant type infests the Adriatic lagoons, the Tuscan Maremma, the Roman Campagna, Apulia, most of the Calabrian coast, and Sicily and Sardinia. At the beginning of the 20th century over 13,000 deaths a year were set down to malarial fever. Since then, the use of quinine and drainage operations have gone far towards stamping out the disease.

The vegetation of Northern Italy is in the main such as can endure the frosts of winter. But by the lake-sides we find olive, and on occasion orange, trees, and the summer heat is sufficient to ripen rice and maize, of which, as well as other cereals and legumes, large crops are raised. Forests of chestnuts clothe the mountains, vineyards the lower hills, and the mulberry-tree is extensively grown. The Riviera, so far as vegetation is concerned, belongs to Southern Italy, and the date-palms and orange-trees are continued at slight intervals along the Tuscan coast. In the interior of Central Italy, however, the vegetation still presents much the same features as in the Lombard plain, and it is only in Southern Italy that the Mediterranean flora prevails. Here, in the lowlands from Monte Gargano and Terracina south, the flora of Central Europe gives place to palms and orange and lemon and citron trees, the cactus and agave, laurels, myrtles, oleanders, and forests of arbutus and the evergreen oak. Only at elevations above 2600 feet do the chestnut and oak reappear, and higher still the beech; the birch and fir and pine are confined to the Alps.

Agriculture.—Italy is pre-eminently an agricultural country. Of its entire area almost the whole is in some degree or other productive, the unproductive tracts embracing only the higher mountain districts and the marshes. Even so, the country is not self-sufficient in point of food supply, and despite protective tariffs, drainage, irrigation, and deforestation schemes, and schemes for increasing technical efficiency and for encouraging more intensive cultivation, cereals continue among the heaviest items of annual import. Speaking generally, bread is the staple food of the Italian population, and wheat-raising is in consequence an agricultural industry of first importance. In Italy wheat is grown almost everywhere, often under highly unfavourable conditions, with the result that the general average yield is low, even although in certain parts, as in Ferrara, Rovigo, and lower Verona, prodigious returns are obtained. Maize, grown chiefly in the irrigated plains of Lombardy, Venetia, and Emilia, follows wheat in importance as a cereal. Of rice Italy is the greatest European producer. The crop is raised almost solely in the valley of the Po, but the area under cultivation tends to decrease chiefly because of difficult conditions of working, and because of the exhausting effect of the crop on the soil. Barley is produced in Sicily and Sardinia, and used to be consumed as food and fodder, but is now absorbed by the Italian breweries. Oats and rye are chiefly used as fodder. Potatoes are grown in the mountainous regions of the Abruzzi, Campania, Lombardy, and Piedmont, but their use as human food is not of such importance as in Germany and Britain. Beans, haricots, peas, chick-peas, and lupines are raised, and besides being consumed as food and fodder are used for green manuring. Tomatoes and cabbages and cauliflower and other vegetables are grown in large quantities. Hemp and flax, once valuable, have lost their former importance. Tobacco is cultivated under state supervision mostly in the provinces of Lecce, Benevento, Vicenza, and Belluno. Sugar-beet is grown principally in Venetia and in Emilia, its culture having developed as a result of the heavy tariff protection granted to the national sugar industry. The grape harvest in

Italy is second in importance to the cereals alone, and in value exceeds any one of them. The area under vines has been very greatly increased since the middle of the 19th century, especially in Piedmont, Southern Italy, and the islands; and the government has established several schools of viticulture, besides expending considerable sums in defending the vines from the attacks of phylloxera. Vineyards occupy something like a third of the whole cultivated area of the kingdom, and in world wine production Italy is second only to France. The Italian wines are, however, still comparatively poor, not so much owing to the quality of the grapes as to the backward technical conditions of the industry. As a result only a very small percentage of Italy's total wine production is exported. Within Italy itself the consumption of wine is very high. When in Austrian hands Gorizia-Gradisca was thought to produce some of the finest wines in Austria-Hungary. Below the 44th parallel the olive is among the most valuable products, and Liguria, Tuscany, Apulia, Calabria, and Sicily produce fine olive-oil in great quantities; ravages of disease and of the fly (*mosca olearia*) have been considerable, but, with Spain and Greece, Italy leads the world in olive-oil production. For oranges, lemons, bergamots, &c., Sicily is the centre. Much of the crop is exported, but part is used in the manufacture of essential oils, lime-juice, &c. Less important fruits are the apple, fig, peach, apricot, and prickly pear. About one-sixth of the surface of Italy is under wood, though the area tends continually to decrease through the encroachments of agricultural expansion. Territorial acquisitions after the Great War added considerable wooded areas in Trentino and Istria. In part the forests are state-owned. The almond, walnut, and hazel, the sumach, cork, manna ash, and dwarf palm, and much more the mulberry, are all of value. Finally, the chestnut is not only a prominent tree in the upland districts, but yields an important article of food; yet the use of cereals is gradually becoming more general, and on the lower hills chestnut-groves are giving place to vineyards.

Since 1880 there has been an almost constant increase in the area devoted to meadows and pastures, but though the live-stock industry has developed, the number of cattle per head of population remains one of the lowest in Europe. Northern Italy is famous for its dairy districts, and large co-operative dairies have been established, especially in Lombardy, in Venetia, and in the valley of Aosta. The well-known Parmesan cheese is manufactured from Lombardy to Emilia, Gorgonzola also in Lombardy, and Gruyère in Piedmont. Butter and meat are exported, and also live cattle; but the exports of these last have diminished, seemingly owing to errors in breeding and feeding.

The extent of cultivable land in Italy is being increased, both by deforesting and by the reclamation of land from the rivers and swamps. Cultivation is still carried on in a very primitive fashion in some parts, but in others modern methods, helped out where necessary by co-operation, are employed. In Northern Italy, Tuscany, and round Naples, indeed, the farming is of a very high character. Double crops in the same year, as of beans after wheat, are often the rule, and it is not unusual to see olive-orchards where vines are planted beneath the trees and crops of some kind fill the space between the rows. Irrigation is more extensively employed every year; but the expense attending its use has helped, except where co-operative methods have been adopted, to keep much of the land in the hands of large owners. Nevertheless, the system of peasant proprietorship is extending. Otherwise, land may be held by the

metayer system, or by rent, paid either in money or in kind; or the cultivator may be simply the paid servant of the landlord, receiving a share of the produce for his labour. Conditions in the agricultural industry have tended as a whole to improve. In former days they were oppressive, and it was in the economic discontent of the peasantry that in the later 19th century Socialism (q.v.) in Italy had its origin.

Fisheries.—There are various fisheries round the coast and in the lagoons. The tunny is a valuable fish, as also the anchovy and sardine; and the eel-fisheries of Comacchio (q.v.) are, too, of importance. The *grande pesca* (i.e. fisheries carried on outside the boats' own districts or on foreign coasts) includes coral and sponge fisheries. The principal fishing-grounds are off the coasts of Sicily, of Tunis, and of Istria and Dalmatia. Sponges are fished off Sicily and Tunis, and coral off Tunis, Algeria, Morocco, and the Italian islands. The coral, of which, however, Japan is now the chief provider, is sent across to the mainland in the rough state, and is worked chiefly at Torre del Greco, Naples, Leghorn, and Genoa. Large numbers are employed in the sea-fishing of Italy, but the industry as a whole is backward, and only a meagre living is obtained.

Minerals.—Except for some mines in the former Austrian territory of Istria, Italy contains no deposits of bituminous coal. A very little anthracite and some lignite are raised annually, most of the latter in Tuscany and Umbria; and peat is found in many districts. Nearly all the iron is raised in Elba (q.v.), and some in Lombardy and Piedmont. The great mineral product of Italy is sulphur, which is obtained almost entirely in Sicily, and which predominantly supplies the European market. After sulphur the principal minerals are zinc ores, lead ores, lignite, iron ores, silver ores, mercury, copper ores, boracic acid, antimony, and gold ores. The quarrying of marble, granite, alabaster, &c., is noteworthy. The marble of Carrara (q.v.) is especially famous, as is also the Alabaster (q.v.) of Volterra, near Pisa.

Manufactures.—The industrial development of Italy in a modern sense may be said to date from about 1870, the year of the country's achievement of political unity. Before the close of the century remarkable progress, due in considerable measure to Italian adaptation of German technical knowledge, had been made, but advance was necessarily checked by the almost utter lack of a native fuel supply. Since 1900, however, great progress has been made in the application of hydro-electric power to industry, and in this way, well supplied as the country is with rivers, has been removed an important limitation on Italian industrial expansion. Increasing development has accompanied the new conditions. Of principal importance among Italian manufactures is the silk industry. Its great seat is Northern Italy, and especially the province of Como. The silk warehouses and silk market of Milan are world renowned. Raw silk is the main product of the industry. Of this the greater part is sent abroad, but some is worked up at home, and piece-goods are also exported. After silk, cotton is the principal textile, the manufacture of thread and of cotton tissues having made great advance since the later 19th century. The progress of the woollen industry has been less pronounced. The hemp, flax, and jute industries are of relatively small proportions. The metal industries, of which iron is the chief, have never been important in Italy, but here the new conditions of industrial electrification are of special consequence. The machinery manufacture has for its chief centres Turin and Milan; but much machinery is still imported. Many automobiles are built. The

shipbuilding industry ranks high in technical process; territorial acquisitions after the Great War added the important shipyards of Monfalcone, Pola, Trieste, and Fiume. The manufactures of glass and ceramic wares are typically Italian; the former include the famous Venetian glass, and the latter majolica, faience (so called from Faenza), and other valuable wares. With these may be classed the cutting of cameos and the production of mosaics at Rome, Naples, and Florence, and also the working of coral. Large quantities of flour-pastes, comprehensively known as 'macaroni,' are manufactured principally from foreign wheat, which is harder than the native grain. Besides spirits, made mostly from maize, Italy produces marsala (in Sicily), vermouth (Piedmont), chianti (Tuscany), maraschino (Zara), and other wines and liqueurs. Under a prohibitive protective tariff the sugar industry has grown enormously, the country being practically self-sufficient in point of sugar supply. The manufacture of tobacco is a government monopoly. The output of the tanneries affords a considerable export of gloves. There are numerous paper-mills in Piedmont, Lombardy, and Campania, and factories of straw-hats, the principal at Florence, and of cloth, silk, and felt hats in Piedmont especially. The production of fertilisers is the main activity of the chemical industries, and the output of superphosphates is very great. Other chemical and allied manufactures are sulphuric and tartaric acid, sulphate of quinine (made at Milan and Genoa), salt, soap, oils, candles, wax matches, &c. Bricks, concrete, and chalk are produced, and musical instruments, especially organs, violins, violas, mandolines, and guitars are widely manufactured.

Commerce.—In former days Italy gathered to herself the commerce of the Mediterranean and the East. But decline set in with the discovery of the trade routes to the West. A progressive expansion of commerce, however, accompanied the industrial development of the later 19th century and after, and Italy became, as she remains, one of the greater commercial nations of Europe. A long coast-line and good harbours have always been circumstances favourable to Italian commerce, but limitations have been the barrier imposed by the Alps to communication with continental Europe, and the lack in the case of the ports of rich producing or consuming hinterlands. The first limitation the development of railway transport has done much to remove, while as to the second there are important exceptions in the case of the harbours of Venice, Genoa, Savona, while to these since the Great War must be added the ports of Fiume (part Italian) and Trieste. An excess, sometimes greater sometimes less, of imports over exports may be said to be a permanent feature of Italian commerce. The explanation lies in the nature of the internal economy of the country; a dense population necessitates the importation of large quantities of food-supplies, while the prosecution of Italian manufactures is dependent for the most part on raw materials imported from abroad. The divergence between imports and exports is, however, in a measure only seeming, and in normal times, indeed, 'invisible exports,' as the remittances of emigrants and the monies spent by foreign visitors in Italy, go far to effect a trade balance. Wheat, cotton, coal and coke, machinery, timber, iron and steel, wool and woollen goods, fish, coffee, and mineral oils, are Italy's principal imports. Her chief exports are silk (raw and manufactured), cotton (spun and manufactured), fruits, automobiles, wines, hides, hemp, cheese, hats, rubber and gutta-percha, conserves, olive-oil, vegetables, sulphur, and works in marble, alabaster, and coral. Trade is carried on mainly with the United States,

Great Britain, France, and Germany, the order of importance of the several countries having varied at different times. The principal imports from Britain are coal, woollen goods, iron and steel, cottons, machinery, fish; the chief exports thither, silk manufactures, rubber manufactures, automobiles, lemons, canned vegetables, almonds, raw silk. Though far behind Great Britain and the United States in shipping strength, Italy ranks after these countries as among the leading ship-owning nations of the world. During and after the Great War her tonnage was much increased by acquisitions from the enemy in Italian ports and in ports in territories annexed. Even so, however, Italy's mercantile marine is insufficient for her needs, and much of her overseas trade is carried in foreign, especially British, bottoms, the freights paid to foreign shipowners forming an important item in the debit side of the balance of trade. Italy's chief ports have been indicated above. Others of note are Leghorn, Naples, Messina, Catania, Palermo, and the former Austrian port and naval station of Pola. Ancona and Brindisi are also well-known ports. At Zara, acquired from Austria after the Great War, there is a spacious harbour.

Communications.—Italy has few railways in proportion to its area and population, construction having proved difficult and expensive owing to lack of coal and iron, to the mountainous surface of the land, and to the prevalence of malaria in certain regions. The first railway was built in 1839, and the system now extends to about 13,000 miles, some 900 miles of which were acquired from Austria after the Great War. Since 1906 most of the railways have been owned and operated by the state; from 1885 till that time they had been let to private companies. A part of the system has been electrified, and economies in working have resulted. Railways run the entire length of Italy on both sides of the peninsula, connection between the two being established by means of various trans-Apennine lines. In Northern Italy, especially in Piedmont and Lombardy, in which last lies Milan, the principal railway centre of the country, there is an extensive railway network, insufficiently connected with the south, but linked on the north with the Austrian and Yugoslav railways, and, by means of the noted tunnels of Mont Cenis, St Gothard, and Simplon, with those of France and Switzerland. There is also a coast line from Genoa to Nice. Road-making is a traditional occupation of the Italian labourer, but the road-system of Italy, with a few notable exceptions, is comparatively poor; nevertheless there has been a considerable development of a public motor transport service. The length of navigable canals, mostly in the basin of the Po, is about 700 miles. The rivers are navigable for about 1000 miles. Financial difficulties have interfered with the completion of an inland water-way joining Lake Maggiore with the Adriatic.

Social Conditions.—In different parts of Italy social conditions vary widely, those of the north being superior, speaking generally, to those of the south. Of the working population, the greater number are employed in agriculture. Nevertheless, the proportion of inhabitants congregated in cities is unusually large, and in Southern Italy and the islands even the peasants prefer to have their homes in some town or village. The sanitary condition of these towns is often deplorable, and at the end of the 19th century the death-rate from infectious and contagious diseases was more than three times as great as that for England and Wales. Yet a general improvement has taken place in the hygienic condition of Italy, and the death-rate has markedly declined, the figure being

lowest in the north. The annual death-rate from malaria has rapidly dwindled away, and that from *pellagra* is diminishing. In the later 19th century bad labour conditions prevailed in the agricultural and in the rising manufacturing industries of Italy. But subsequent improvement took place, the 20th century in especial being marked by a more or less general advance in wages and conditions of work. This improvement has been due in part to direct gains obtained as a result of the growth of working-class organisations as trade-unions, 'chambers of labour' (for purposes of technical education, arbitration, political propaganda, &c.), provident societies, and co-operative societies (for purposes of credit, distribution, production, and labour), but also in part to the more indirect gains obtained as a result of legislation inspired just by the growth of working-class organisations themselves, and by the spread of Socialist doctrines. Among legislative achievements have been the general regulation of conditions of work in factories and elsewhere, the institution of a weekly day of rest and of an eight hours' day, and the inauguration of workmen's compensation, old age pension and accident and health insurance schemes. A high frequency of strikes has been a marked feature of Italian industrial history. The relief of the poor is not recognised as a charge upon public funds, charity falling to be exercised through various permanent charitable foundations (*opere pie*). The food of the artisan classes consists mainly of cereals and beans; maize is mostly used in the north, where also the small proportion of animal food is larger than that consumed in the south. The diet of the peasantry, again, almost never includes meat or fish. Wine is the prevailing drink. The character of the people is in general sober and thrifty, the inhabitants of Northern and Central Italy being more industrious, stable, and trustworthy than those of the south. The Italian proves an excellent workman, not only where sheer labour is required, as in quarries and drainage operations, but also in work requiring high technical and mechanical skill. Moreover, the old Roman spirit of stern utilitarianism is stronger in the sons of modern Italy than the æsthetic artistic temperament principally associated with them in many minds: the national type must rather be described as thoroughly practical; the 'improvements' wrought on Rome, Florence, Naples, the miles of new streets, the staring blocks of modern houses, Paris-like, that have displaced the picturesque squalor of a generation ago, are sufficient evidence of this. Of Italian emigrants many hope some day to return to their own land with a competence: in this respect the Italian love of country appears only less strong than the Chinese. The national character is passionate and quick to resent an injury, and among European countries Italy and Spain show proportionately the highest annual number of homicides; there is a tendency, however, for the frequency of the crime to decrease. Capital punishment was definitely abolished in 1889. Assaults and woundings are also very numerous, and as regards all these offences against the person the southern provinces and the islands enjoy a grim pre-eminence. See **FOUNDLING HOSPITALS**.

Religion and Education.—Religious freedom is now secured to all creeds, but the Roman Catholic is the recognised state religion, and claims all but a very small fraction of the people. Of other professions, the Protestant—a notable section being the Waldenses (q.v.)—and the Jewish are the chief. The rank and dignity of the pope, as a sovereign prince, is recognised by the law of 1871, which defines the relations of the church and state; his person is sacred, his residence inviolable, and he has his own court in the Vatican (see **ROMAN**

CATHOLIC CHURCH). Under a series of laws the great majority of the religious houses have been suppressed, small pensions being paid to most of their inmates who had taken vows, and their property confiscated. Part of the funds thus placed at the disposal of government have been devoted to educational purposes.

Education is under a minister of public instruction, who is assisted by a council; and in every province there is an educational council. Instruction is of three kinds, elementary, secondary, and higher. Elementary and secondary education are given in both public and private schools, but the latter are required to conform to the rules of the former. Elementary education is free and in its earlier stages compulsory. Public instruction generally is maintained either entirely by the state or by the state in conjunction with the communes and provinces. The former more or less complete dependence of elementary education on communal finance was often unfavourable to educational advance, both because of the poverty of certain communes and because of an antagonistic attitude in certain instances to universal instruction. At the formation of the kingdom of Italy the general ignorance was incredibly profound, although learned societies existed in every large town, many of them, like the universities, of European fame (see **ACADEMY**). As regards education, Italy still comes behind most of the nations of Europe; yet notable progress has been made. In 1871 illiterates were numbered at about 73 per cent. of the population, but forty years later the figure had been reduced by about one-half; and the tendency to progressive diminution continues. The various parts of the kingdom differ widely in point of illiteracy, the figure for the southern regions being very much higher than that for those of the north; thus while in Piedmont there are about 11 per cent. illiterates, in Calabria the rate is as high as some 70 per cent. In 1919 a national institute for the instruction of illiterate adults was established. Although the universities nominally are open to women as well as men, there is much less adequate provision for the higher education of girls. The convent schools teach mainly embroidery and devotions, and the government and superior schools are not satisfactory. In 1861, however, a good high school for girls was opened at Milan, and its success has led to the establishment of many similar schools in other towns. Elementary education is of three grades, preparatory, secondary, and higher, and is given generally in separate boys' and girls' schools and in *asili* for infants; the number of pupils has tended very greatly to increase. Secondary education (male and female) is given in supplementary, normal, and technical schools, in technical institutes, and in *ginnasi* and *licei*, the *licei* leading to the university. Higher education is given in the universities, in some few lycæums and higher institutes providing courses of university standard, and in various special schools of teaching, languages, commerce, agriculture, engineering, forestry, and of naval, veterinary, and social science. There are also conservatoria of music and fine art schools. The universities number 24, most governmental, but others 'free'—i.e. maintained by the provinces and communes. The oldest university is that of Bologna (q.v.), the largest that of Naples. In 1924 three new universities (Bari, Milan, Trieste) were opened. The great body of Italian students are enrolled in the faculties of medicine and jurisprudence; theology is not taught in any of the universities, but in seminaries. In 1923 the entire educational system was revised. Generally, the burden on the state was where possible lightened, and all non-state educational estab-

lishments were encouraged to collaborate with the state: particularly, religious instruction, an improved curriculum, and better methods of staff selection were introduced into elementary schools; state in place of teacher examiners were instituted in secondary schools; administrative independence was conceded to all institutions for higher learning. Libraries are numerous in Italy, those even of small cities being often rich in manuscripts and valuable works; the libraries are both public and private, the first having been greatly enriched after 1870 by the incorporation of the treasures of suppressed monasteries (see LIBRARY).

Government.—Italy is a constitutional monarchy, the executive power vested in the king, with succession in the male line, being exercised through responsible ministers. The legislative functions lie with the king and parliament conjointly, the latter consisting of a senate and chamber of deputies. The number of deputies is 560. In 1920 the franchise was extended to all male citizens of twenty-one years of age or over. Election (since 1919) is by *scrutin de liste*, according to the system of proportional representation; this system was carried to its extreme by the law of 1923, whereby the whole country was formed into one constituency of fifteen districts, the party obtaining a majority of the entire nation having sufficient seats (two-thirds) allotted to it to make its voice decisive in the chamber. In 1925, however, a return was made to the system of one-member constituencies. The senate is composed entirely of life-members, with no fixed limit as to numbers (at present about 400); all its members, except the princes of the royal family, are nominated by the king, and must be forty years of age or upwards. Deputies are paid, partly directly, partly by arrangements for free railway travelling. Money bills must originate in the Lower House. The parliaments are quinquennial, but may be dissolved by the sovereign at any time. Ministers are not necessarily members of either house. The government of the provinces, with a prefect at the head of each, is very much the same as in France.

Defence.—Military (for the maritime population, naval) service is compulsory for all citizens from the age of twenty to thirty-nine. Recruits are divided into three classes, those of the third entering the territorial militia at once, and, after undergoing thirty days' training, receive unlimited leave. Recruits of the second category are enrolled for eight years in the permanent army (with unlimited leave, except for from two to six months' training, which may be spread over several years) and four in the mobile militia (landwehr), and then enter the territorial militia for seven years. Recruits of the first category have, before being transferred to the territorial militia for seven years, eighteen months with the colours, eight on leave, and four in the mobile militia. The standing army (exclusive of carabinieri) numbers about 250,000 men; the total war strength, including mobile and territorial militia, is over three million men, about one million of whom have received a regular training. The carabinieri (60,000) perform the duties of gendarmes. There are a staff-college and a school for artillery and engineer officers at Turin, others for infantry and cavalry officers at Modena and Parma, for cavalry officers at Pinerolo, and for the sanitary corps at Florence, and military colleges at Milan, Florence, Rome, Naples, and Messina. A chain of fortresses defends the principal Alpine passes along the northern frontier; there are numerous forts and batteries in the basin of the Po and along the coast and on the islands; and Rome is protected by a circle of forts.

After the disastrous defeat at Lissa in 1866 the navy was reconstructed, and years of exertion

made Italy for a time one of the strongest maritime powers of Europe. Two of her armoured-clads, the *Italia* and *Lepanto*, were in their day the largest warships afloat. In 1896 Italy was regarded as ranking next to France in naval strength; but in 1914 her fleet came after those of Britain, France, Germany, and the United States, and the Great War occasioned some losses; on the conclusion of peace a policy of large reduction in the main was followed. The numbers of officers and men on active service in the navy is about 40,000. Spezia and Pola are the leading naval ports. The period of service in the navy is twenty-two years, but a limited number only of the conscripts actually serve four years, and the rest are normally on permanent leave.

In 1923 the growing air service in its naval and military branches was constituted as a separate force.

Finances.—From the first the young kingdom of Italy was burdened with the cost of the war with Austria and the debts of the old Italian states, and, moreover, was obliged to face many years of extraordinary outlay; whilst the land, especially in the south, was not developed to anything like its full capacity, its revenue yield being restricted in consequence. In these circumstances the adjustment of revenue and expenditure proved difficult of achievement. In 1862 there was a deficit of nearly £18,000,000, and it was not until 1875 that the first small surplus was obtained. Except the first half of 1884, however, the next ten years showed a surplus, larger or smaller; but from 1885 there were deficits, until surpluses began again in 1898, and continued, notwithstanding increased military expenditure necessitated by the Italo-Turkish War (1911–12) and the occupation of Libya, until the circumstances of the Great War and the period immediately following resulted in deficits in several years. Both income and expenditure have steadily increased, and taxation is burdensome and vexatious. The chief sources of income are excise, customs, the income, land and house taxes, and various state monopolies. Among methods devised to meet the situation created by the Great War were, an enormous increase in the inheritance tax, and an excess profits tax, which in the end became a complete appropriation of war profits. These imposts, however, were subsequently abandoned, a policy of simplification and better enforcement of old methods of taxation being adopted. The principal expenses are the interest of the public debt, and the cost of the army and navy, and of education. In proportion to the productivity of the country Italy's public debt is very heavy. At the end of 1861 it was slightly over £125,000,000; but a long succession of annual deficits, extensive railway and other public works, and costly armaments raised it year by year, till at the beginning of the 20th century it stood at over £500,000,000, or about £15 per head of the population, exclusive of communal and provincial debts, amounting jointly to over £50,000,000. The total debt has since increased. Italy entered the Great War with a debt of about £637,000,000, and emerged from it with one of some £2,000,000,000, a figure which rose in 1923 to close on £3,000,000,000, but thereafter was steadily reduced.

For information on Italy the best sources are the admirable official publications, a complete list of which appeared in the *Saggio di Bibliografia statistica Italiana* (3d ed. Rome, 1890). The *Annuario statistico Italiano* (published since 1878) contains topographical as well as statistical information; most of the statistical portion will be found summarised in the *Statesman's Year-book*. Ethnology.—Italian ethnology is extremely complicated. From before the dawn of history Italy has been invaded by race after race. As the seat of a world-power it received peaceful immigrants and slaves. Early traditions are difficult, and many confident assertions of ethnologists impossible, to reconcile. At many points only provisional results more or less probable can be given. One race at least was so early as to be considered autochthonous and to be named Aborigines. These have been identified with the Ligurians or Ligyes, who ranged from Spain to the Adriatic, and seem to have shaded off into Iberians and Illyrians. All these are believed to have belonged to the small, dark, long-skulled race characteristic of the Mediterranean. Of the language of the Ligurians very little is known. It seems to have been Indo-Germanic, and reasons have been shown for assigning it to the same subdivision of the Italic group to which Latin and Faliscan belonged. Some go as far as to hold that Latin was Ligurian. To the Ligurians are assigned by some the *terramare* or *terremare* (see *TERRAMARA*), which abound chiefly in the Po basin, but are found in other parts of Italy as far south as Tarentum. The refuse-heaps of these pile-dwellings indicate first the Neolithic stage of culture, passing soon into the Bronze Age. Others assign the *terramara* culture, as well as the Villanova which succeeds, to the Umbrians. The Villanova culture, well represented in the Bologna district, is of the Hallstatt or early Iron Age. It is thought that the invading Umbrians brought it from their home beyond the Alps. They seem to have been preceded by the Sicels or Siculans, who were perhaps of kindred stock. The Ligurians were driven into the Apennines, while the Siculi on this hypothesis were pushed southward, and became one of the chief races of Sicily, where they must not be confounded with the Sicani, who are said to have come to Sicily from Spain. Apparently of the same kindred were the Saffnes, Sabines, or Samnites, who drove the Ligurians before them in Central Italy. In Latium the conquests of the Sabines were most momentous, for the population of Rome in early times seems to have been composed of conquered Latins (the plebs) and ruling Sabines (the patricians), who retained in their religion and culture many marks of their origin while they adopted and modified the language of their subjects. There is reason to believe that the Umbrians and Saffnes were branches of the tall, fair race that still inhabits northern Europe. Successive invasions of this race, under various names—Gauls, Goths, Lombards, Normans—were to form a great part of the history of Italy. A similar movement into Greece, where the newcomers were called Achæans, has been held to account for the coming of dispossessed Pelasgians across the Adriatic to Italy. This mysterious race may have been akin to the Aborigines, with whom it is said to have joined forces against the Umbrians and Siculans. But however this may be, there was probably much migration across and round

the Adriatic, both from Illyria and from Greece. At the head of the Adriatic the Umbrians subdued the Veneti, probably a link—if the scanty but remarkable linguistic evidence is to be trusted—between Ligurians and Illyrians. In the south-east corner of Italy were the Messapians and Iapygians (if these are not two names for the same people), who are also believed to have come from Illyria. Both these and the Veneti some connect with the Eteocretans. Much farther east was the home of the Etruscans, Tuscans, Tyrrhenians, or Tyrsenians (see *ETRURIA*), according to the tradition, which many ethnologists are disposed to accept, that they came from Lydia. They seem to have reduced the Umbrians, without perhaps greatly modifying the racial constitution of the population in some districts. Rome seems to have fallen under their domination for a time, but the Roman people remained on the whole Latin and Sabine. From the 8th to the 6th century B.C. numerous Greek cities were founded in Southern Italy—Magna Græcia—and Sicily. The southward movement of the tall, fair race, checked perhaps by Etruscan conquests, began again with the Celts. The north of Italy had already been in Gaulish hands for centuries, and was the seat of a civilisation of the La Tène type, when the incursion of 391-390 B.C. resulted in the defeat of the Etruscans and the sack of Rome. Phœnician colonies in Sicily and Sardinia added a new element. Although many of the races inhabiting Italy were ultimately, in name at least, restricted to limited regions, most of them seem at one time or other to have extended over a wide area, and their descendants are more widely spread than their names. Centralisation of power at Rome meant more or less thorough mixing of the races of Italy. Later, the influx of slaves, adventurers, and others from foreign countries was such that some writers regard the newcomers from the east, rather than the Ligurians, as forming the basis of the present Italian type. If complaints against the 'Græculus esuriens,' and Syrian Orontes flowing into the Tiber, look like exaggerations, one has but to run over the list of men famous in Roman history and literature under the Empire to see how numerous were those who were not Italians. The still later invasions and dominations of Italy, in whole or in part, by Herulians, Ostrogoths, Byzantines, Lombards, Franks, Huns, Saracens, Vandals, Normans, French, and Spaniards, and the long connection with the German and Austrian empires, are dealt with in the section *History*, and in the articles *SCILY*, *LOMBARDS*, &c. These, with immigration of Albanians and others, must have profoundly modified the race; but though there are still linguistic islands where Albanian, Greek, German, Catalan, and Slavonic languages are spoken (to say nothing of the solidly German and Slav country acquired by the treaties of St Germain and Rapallo, 1919-20), and though the Italian of the north differs physically and mentally from the Italian of the south, the nation is remarkably homogeneous. The conditions of life have favoured the small, dark Mediterranean type.

Ancient Languages.—The languages of the Greek and Phœnician colonists, the Etruscans, and the Gauls, are dealt with in the articles *GREECE*, *PHœNICIA*, *ETRURIA*, and *CELTS*. Messapians, the so-called Old Sabellian of the middle Adriatic coast, and Venetic possibly belong to an Illyrian family, but of these so little is known that it is unsafe to say more than that the first and last are Indo-Germanic, and that they promise important results to future research. The majority of the ancient languages of Italy belong to the Italic family, which is closely related to the neighbouring Celtic family, less closely to Greek. With Celtic

Italic shares the passive in *-r*, the second declension genitive in *-i*, and other features; and as the Celtic languages fall into a P group and a Q group according to the degree of labialisation of the Indo-Germanic velar *q* (as in Welsh *ap* for *map*, Old Irish *mag* = son), so do the Italic. Thus for Latin *quod* we find Oscan *pod*. The Q group consists of Latin (see LATIN LANGUAGE AND LITERATURE), and Faliscan, the dialect of Falerii, of which not much is known. Of the P group, which differs in many respects from Latin, the most important dialects are those known as Umbrian and Oscan. In Umbrian, for which Iguvine has been suggested as a safer name, the principal documents are the Eugubine Tables (q.v.). For Oscan there are many shorter inscriptions of various kinds. It was the language of the Samnites of Campania, to whom was extended the name of Osci, belonging more properly to the earlier inhabitants. It is believed that the Campanians were for long more highly civilised than the Romans, and that they had a literature, though the language and the place of origin of the Atellan farces are disputed (see ATELLANÆ). Besides Oscan and Iguvine, there are scanty remains, in inscriptions, of Pælgian, Volscian, and Marrucinian, all of the P group, and a few words of Sabine have been preserved. Very little is known of Ligurian. The modern Italian language is treated in a later section.

HISTORY.—The ancient history of Italy will be more conveniently treated of under ROME; see also ETRURIA, UMBRIA, &c. In 476 A.D. the Herulian mercenaries in the pay of the western empire rose in revolt, and proclaimed their leader Odoacer king; and the last emperor of the West, the pretty boy Romulus Augustulus, was sent to end his days amid the woods and fish-ponds of Lucullus' villa near Naples. The senate, by Odoacer's command, recognised Zeno as head of the western as well as the eastern empire, and he in turn bestowed on the Teuton leader the dignity of 'patrician.' For thirteen years Odoacer's rule was undisputed; but in 489 Theodoric, king of the Ostrogoths, invaded Italy with a commission from the Greek emperor, besieged the Herulian in Ravenna, and in 493, after his surrender, slew him with his own hand. In spite of this bloody beginning, Theodoric's rule, which lasted till 525, was wise and, on the whole, just. But the Arian faith of the conquerors held them and the Italians apart, and when Justinian's general Belisarius was sent to reconquer Italy he was welcomed by the colonists of Sicily and the south. From 536 to 553 the war was desperately maintained, the hero on the Gothic side being Totila (541-552). But the valour of the barbarians was outmatched by the generalship of the aged eunuch Narses; and in 553 Teias, the last king of the Goths, was slain in battle, and the descendants of the host who had followed the Amal king into Italy sixty-four years before, now few in number and sore at heart, were permitted to march back across the Alps. Italy was now governed from Ravenna for a few years by an exarch or viceroy; but in 568 came an invasion by the Lombard nation, under their king, Alboin, and all the central portion of the peninsula passed from under the sway of Byzantium. Pavia was made the capital of the new kingdom, and the great duchies of Spoleto and Benevento were founded, pressing on Rome and the Greek maritime cities of the south. Yet the Lombards were not strong enough to occupy the whole peninsula, and Rome and most of the coast towns, as well as the islands, remained to the emperor. The invaders imposed on the country a sort of feudal system, and, being Arians, treated the Italians with great harshness, until Gregory the Great effected their conversion to orthodoxy. From this

period the popes for a time appear as the champions of the national cause. Leo the Isaurian's decree against the worship of images was met by Gregory II.'s declaration of Roman independence; and in 726-56 the popes succeeded in driving out the exarch and checking, with the help of the Franks, the encroachments of the Lombards. Pepin twice crossed the Alps, compelled the Lombard king to yield up the exarchate and the Pentapolis, which he had conquered, and presented them to the pope in 756: this gift was the nucleus of the temporal sovereignty of the bishops of Rome.

In 774 Pepin's son, Charlemagne, who had been summoned to the aid of the pope, deposed Desiderius, the last Lombard king, and added his dominions to his own; in 800 he was crowned emperor of the Romans. Meanwhile the Lombard duchies in the south were still independent, and Sicily and a number of free cities in Southern Italy, as well as Venice, recognised the Greek overlordship. But in the 9th century the Saracens subdued Sicily, landed on the mainland, and even threatened Rome. Leo IV. fortified the suburb on the north bank of the Tiber, which after him was called the Leonine city, and called to his aid Louis II., Charlemagne's great-grandson, who, with the help of the eastern emperor, checked the progress of the Saracens for a time. But after the death of Louis the infidels compelled the helpless pope to pay tribute; and the Greeks, profiting by the weakness of Charlemagne's successors, recovered most of Southern Italy, and held it, under an officer entitled Catapan, till 1043. Eight kings of the Carolingian line were acknowledged in Northern Italy, their rule ending with Charles the Fat in 887. Then, till 961, succeeded ten so-called Italian sovereigns—dukes of Spoleto and Friuli, the German Arnulf, Hugh of Provence, Berengar, marquis of Ivrea, and others. Under their feeble sway the power of the feudal nobles, and, within the cities, of the bishops, waxed great, the papal chair was occupied by men of infamous life, and Magyars, Saracens, and Northmen overran the country, turning wide tracts into a desolate wilderness. In 951 Berengar II. was compelled to do homage to the German king, Otto of Saxony. He was suffered to rule until 961, and then deposed; and in 962 Otto was crowned as king of Italy at Milan and as emperor at Rome. From this time the right to the crown of the Roman empire (two centuries later it was the Holy Roman empire) was held to accompany the German kingship. Except in name, there was no longer an Italian kingdom, and, with its foreign emperors occupied for the most part beyond the Alps, the country was in some degree left masterless. Its division into separate states was now but a question of time.

Moved by the scandals of the papacy and the constant revolts in the city, Otto took the election of the popes away from the Romans, chose a pope of his own, and put the city in his charge. Elsewhere he encouraged the rise of the communes as a check upon the great vassals. The towns had already been permitted to raise walls as a defence against the barbarians, and now the chief cities were freed from the jurisdiction of the counts. The death of Otto III. in 1002 was followed by a dispute for the crown; Rome, the papacy and the city, fell again into the hands of the Tusculan counts, while the Lombard cities gained in importance as their alliance was sought by one side or the other. Milan supported Henry of Bavaria, who had been elected in Germany; and he severely punished her rival Pavia, who had espoused the cause of the Lombard Ardoïn. Henry died in 1024, and was succeeded by Conrad of Franconia, who was invited into Italy and crowned with the iron crown at Milan, by Heribert, the

archbishop. Under this prelate Milan advanced greatly in power and independence. An effective militia was formed, and Heribert is said to have invented the *carroccio*, a car which carried into battle the city's banner and an altar, and round which the burghers fought as in defence of a sacred thing. The citizens had already formed themselves into a *parlamento*, and, while Heribert lived, the power of the smaller counts who had now come to dwell in the city was bridled. The other Lombard cities also were rising into some degree of independence. Pisa and Genoa, besides Venice (which acknowledged the nominal sovereignty of the Greek emperor), were becoming great by their command of fleets; and they succeeded to the rich carrying trade of the Mediterranean after the fall of the Greek cities in the south before the Normans. During the first half of the 11th century a body of Norman adventurers had gained a firm footing in Apulia, which they ultimately conquered as a county for themselves. The pope, Leo IX., marched against them, and was defeated and taken prisoner by Robert Wiskard or Guiscard at Civitella (1053); and Wiskard obtained from him the investiture of his present and future conquests, which he was to hold as a fief of the holy see. Robert extended his power on the mainland, and took the title of Duke of Apulia and Calabria in 1059. In 1060-90 his brother Roger conquered Sicily from the Saracens; in 1127 the family's dominions in Apulia, Calabria, and Sicily were united by his son Roger, who in 1130 assumed the title of king of Sicily.

Meanwhile the fierce struggle over Investitures (q.v.) had been fought out between emperor and pope. When the archdeacon Hildebrand became Pope Gregory VII. (1073) he enforced the celibacy of the clergy, as Leo IX. had already endeavoured to do; and in 1075 he condemned the investiture of ecclesiastics by lay lords. Otto the Great and Henry III. had appointed and deposed popes, and therefore this latter decree led to a quarrel with Henry IV. (q.v.). At a diet in 1076 Gregory was deposed. The pope replied by excommunicating the king, who was compelled by a rebellion in Saxony to submit and do penance at Canossa, the castle of the Countess Matilda of Tuscany, the pope's ally. Henry, however, soon renewed the strife, appointed an antipope, and in 1084 took Rome, was crowned, and besieged Gregory in the fortress of St Angelo. Thence the pontiff was delivered by Wiskard, who drove the emperor off, and carried Gregory away from his riotous subjects to end his days at Salerno. The struggle, however, was carried on by Gregory's successors, till by the concordat of Worms (1122) the emperor yielded the main principle at issue, surrendering to the cardinals the election of the pope, who was still to possess the right of conferring the imperial crown. By the death of the Countess Matilda, too, in 1115, the church had inherited her vast domains; and, although the emperor took possession of them, the popes retained their claim, to be revived in after years.

From this long struggle the northern cities emerged strengthened and practically autonomous. They still belonged to the empire; but they were governed by their own magistrates, called consuls, aided by an oligarchical council; and they enjoyed, and unhappily took frequent advantage of, the right to make war on their own account. The quarrel of the Guelphs and Ghibellines (q.v.) arose in Germany at this time, and before long these names were heard everywhere in Italy; but here they stood not alone for the pope's party and the emperor's, but also for the burning jealousy and hatred of rival cities, each struggling to rise at the cost of its neighbours. Arnold of Brescia (q.v.) for a time established a republic in Rome, but it

was suppressed by Frederick Barbarossa in 1154. In that year Frederick, who had been elected king in 1152, came into Italy to take away the self-government of the towns, and reduce them to their former subjection to the emperor. After punishing several hostile cities, he went on to Rome and was crowned by Adrian IV. (Nicholas Breakspear), the only pope of English birth; but he soon quarrelled with him, and on Adrian's death supported an antipope. In 1158 Frederick returned from Germany, and compelled Milan to surrender, after a month's siege. He now set in every town a podestà to administer justice, who should be chosen always from another city; and from cities and barons alike he took away the privilege of making war on one another without his permission. An attempt to appoint their consuls also drove the Milanese into a second revolt, in 1159; but Frederick was delayed by the heroic defence of Crema, and it was not till May 1161 that he again invested Milan. The city held out till March 1162, and was then destroyed by the vindictive imperialists, and the people driven from the ruins. Soon afterwards the cities of the Veronese march formed a league of defence against Frederick which he was unable to crush. In 1167 he besieged the pope, Alexander III., in the Coliseum; but the latter escaped to Benevento, while a terrible pestilence fell upon the German camp, and Frederick with difficulty led the remnant of his army north to Pavia. Only this city and the Marquis of Montferrat in all North Italy had held back from the great Lombard league, which had meanwhile been formed and had restored the Milanese to their city. In 1168 Frederick fled in disguise across the Alps; and in the same year the confederates founded a new city on the plain between Pavia and Montferrat, to be a check on these two. The league named it Alessandria, in honour of their ally the pope: *della paglia* ('of straw'), their enemies added in derision; but its ditch and rampart of earth held Frederick at bay all through the winter of 1174-75, till he was forced to raise the siege. Finally, the crushing defeat at Legnano (May 29, 1176), from which field he hardly escaped with his life, made him willing to treat for peace. In 1177, at Venice, the emperor came to terms with the pope, and agreed to a six years' truce with the Lombard towns; in 1183 a permanent peace was ratified, the cities retaining their right of war and of self-government, and the emperor his podestàs and his rights of sustenance and support against enemies outside the league. The rule of podestàs was soon adopted outside of Lombardy as well, for the settlement of nobles in the towns had introduced a lawless element and given rise to factions; so that a supreme judge who was not a townsman, who held office for a single year, and had then to render an account of his administration, was most likely to prove impartial. Yet from the podestàs to the despots was but a step, and this was taken a few years later.

Since the battle of Civitella the Normans had continued faithful allies of the popes, and it was with the object of depriving the latter of this powerful support that Frederick now had his son Henry VI. married to the heiress of Sicily. Frederick died in 1190, and in 1194 Henry was recognised as king, and the Norman rule in Southern Italy came to an end. He died in 1197, and the next year his wife, who had acknowledged the pope as overlord, died also, leaving their infant son Frederick to the guardianship of Innocent III. The papal territory had now become extensive, and the establishment of a Latin empire at Constantinople (1204), during the fourth crusade, added to the prestige of the Roman see. But the chief gainer by the capture of the Eastern capital was Venice,

who, as a reward for lending her fleet, was presented by the victorious crusaders with a large share of the divided empire, and was able to occupy at least a number of islands and coast territory: she was now supreme in the Levant. Frederick II., who was crowned emperor in 1220, was king of Italy, Sicily, Sardinia, Germany, Burgundy, and Jerusalem. So formidable a prince made popes and communes both uneasy. He was excommunicated by Gregory IX. in 1227, because he delayed his departure on a promised crusade; and afterwards, when he had gone to the East, while he was crowning himself at Jerusalem his enemies were still busy at home. The pope, whose hands were greatly strengthened by the newly-founded Franciscan and Dominican orders, stirred up the Lombard cities to revolt, and, after Frederick had crushed the Milanese at Cortenuova (1237), drew Venice and Genoa into the league against him. Frederick's cause was upheld in Northern Italy by Ezzelino da Romano, infamous for his cruelties. In 1245 Innocent IV., the emperor's personal enemy, had him declared dethroned by a council convened at Lyons; and after five years of harassing anxiety, his life the object of constant plots, Frederick died in December 1250. The cause of his son and grandson was upheld by his natural son Manfred, who in 1258 became king of Sicily. There was no abatement of fury in the fierce struggle between Guelphs and Ghibellines, but the balance of success so far inclined towards Manfred after the battle of Montaperto (1260), which restored Florence to the Ghibellines, that Urban IV. invited Charles of Anjou into Italy to head the Guelphic party. In 1266 Manfred was defeated and slain, and the Swabian line came to an end with his nephew Conradin, who was beheaded at Naples. The Guelphs were again supreme; but Gregory X. restored their banished rivals to their cities, and for a time made the two parties live in peace. Charles, who received the kingdom of Sicily as the gift of the popes, had promised that it should never be held along with the empire; and now, as a final check to the Angevin's possible ambition, the pope brought the dispute to a close which had kept the empire without a head, and crowned Rudolf of Hapsburg, who was elected in 1273. This emperor in 1278 recognised the popes as temporal sovereigns, and their power was henceforth firmly established over Rome and the Campagna, Emilia, the Romagna, and the March of Ancona; and, as Rudolf left Italy to itself, the Guelphic party was enabled to strengthen its power and to crush such hostile cities as Pisa. Charles lost Sicily by the rebellion which began in the Sicilian Vespers (q.v.), in 1282; and the island gave itself to the House of Aragon, which, as the popes were hostile, necessarily became Ghibelline. Meanwhile, in Tuscany the triumphant Guelphs had become broken up into factions, the Neri and Bianchi (Blacks and Whites), the former violent Guelphs, and the latter at first moderate Guelphs, until the fierce animosity of their opponents made them Ghibellines. For in 1301 Charles of Valois, who had been called in by Boniface VIII. to help the Neri, entered Florence, and gave the Bianchi up to the cruel vengeance of their enemies: among those banished from the city was the poet Dante. Under Clement V. the seat of the papacy was removed, in 1309, to Avignon, where it remained for the next seventy years. In the following year the new emperor, Henry VII., came into Italy to revive the Ghibelline party, and to restore peace and order. The task, however, was now beyond the power of any German master. Henry died in August 1313, having effected no lasting change except in Milan, which he had handed over to the Ghibelline Visconti.

We have now reached a period when the cities of Northern Italy had fallen under the sway of tyrants or despots. The feudal power of the rural counts had gradually been lessened by the communes, until the nobles had become citizens. But they merely exchanged their castles for fortified palaces in the cities; and, although the podestà had curbed their power for a time, his office eventually became not so much that of a dictator as of a judge, and the interminable wars had tended to give the nobles an undue predominance, since, being trained to arms, their military skill naturally placed them above the burghers. In some towns, such as Florence, where the democratic spirit was strongest, they were kept in check by a *gonfaloniere of justice*; but in most cities the *captain of the people*, who represented the party in the ascendant, and in these war-times was of course a noble, gradually raised himself to the position of master. It was then his aim to depress the others of his own order, both to win popularity with the people and to prevent possible rivalry. At the root of the wars fought between those in Italy who called themselves Guelphs and Ghibellines was the question whether the democracy or the aristocracy was to be supreme in the cities. Florence as yet preserved her republican independence; but, besides, a hereditary oligarchy in Venice, despots were now established in all the great northern cities, each of which was glad to submit to a master who would put an end to the strife that had hampered its commercial prosperity. Titles were bought from the German emperors or assumed, courts were formed, and armies were hired; for wars were now waged in another fashion than that which had prevailed in Barbarossa's time. Then it was an honoured custom for the artisans and traders of a city to devote a week or a month in the year to harrying the fields of a rival commune, to draw its defenders into an ambushade, or even to capture and ruin the town, provided it did not hold out too long; in any case, the citizen-soldiers returned home in a few days, and took up their ordinary work again. Now, however, war was a science and soldiering a trade; the iron panoply and ponderous lance of the man-at-arms were not for the craftsman or the clerk. Therefore, in the 14th century, bands of mercenaries, or companies of adventure, under condottieri, made their appearance, selling their services to the highest bidder, or plundering the lands of the weaker states. Their battles were almost bloodless, the campaigns indecisive. Bound by a common profession, they were chiefly formidable to the taxpayer; and, for that matter, in their commercial prosperity the cities were at this time receiving the reward for which they had bartered their independence. If we glance at England in this period, which followed hard on Bannockburn, we find commerce and manufactures still in their infancy, wool the staple export, houses of mud in the streets of the cities, and rushes strewn in the king's chamber: but the nation had now its constitution complete, and was moving in the broadening path of freedom. The condition of Italy was in sharp contrast to all this. Trade and manufactures were flourishing, art and literature were encouraged at the courts, and freedom was forgotten in present comfort and inglorious well-being. The result of the self-indulgent policy now begun was seen two centuries later, when Italy lay helpless beneath the feet of contending foreign armies.

The 14th and 15th centuries witnessed the division of Italy among five principal powers—the kingdom of Naples, the duchy of Milan, the republics of Florence and Venice, and the papacy. In Naples the Angevin line came to an end in 1435 with Joan II. She was succeeded by Alfonso V. of

Aragon, and the Two Sicilies, separate since 1282, were again united. At his death in 1458, however, Sicily remained to the kings of Aragon, while Naples was bequeathed to his natural son. In Milan the powerful Visconti dynasty survived till 1447. Archbishop Gian Visconti, who died in 1354, made himself master of more than twenty cities, and extended the family's power over the greater part of Northern Italy; and these domains were reunited by his grand-nephew, Gian Galeazzo, who purchased the title of duke, made himself lord as far as the borders of Venice, and was threatening Florence when the plague carried him off in 1402. The Visconti's possessions were confined within narrower limits under his son Filippo, and were seized in 1450 by Francesco Sforza, a famous general, who had married Filippo's natural daughter, and who proved a wise and able ruler. Florence had submitted in 1342 to a despot in Walter of Brienne, the titular Duke of Athens; but this soldier of fortune was expelled in 1343, and the city was ruled until 1434, except during a brief revolution, by an oligarchy. The presidency of the republic—practically the dictatorship—was then secured by Cosimo de' Medici, who for this end had courted the good-will of the common people; and his undefined power passed at his death in 1464 to his son, and reached its culmination under his famous grandson, Lorenzo the Magnificent. Florence was already mistress of great part of Tuscany, and Cosimo's alliance with Francesco Sforza helped to secure her position as one of the five great powers. Venice, which had until this period stood aloof from Italian politics, was in the hands of a hereditary grand council. Thirty years of contest with Genoa for supremacy in the Mediterranean had ended in victory for the republic of St Mark in 1381. The capture of Constantinople by the Turks in 1453 made Venice, who had been gradually stripped of her possessions in the Levant, now at last an Italian state; and her territory on the mainland was greatly extended under Francesco Foscari (1457) and his successors in the dogeship, although in 1477 a Turkish army ravaged her fields to within sight of St Mark's. Rome, except during Rienzi's brief rule, had obeyed her bishops, exiled at Avignon. In 1377 the papacy returned from the Babylonish captivity, and, in spite of the weakness caused by the Great Schism, the spiritual sovereign also was soon found among the despots. The schism ended in 1449, and Nicholas V. was enabled to establish firmly the temporal power of the papacy.

Italy now enjoyed a term of prosperity and comparative peace, broken only as Venice enlarged her borders, or by the family ambitions of the popes. But in 1494 Charles VIII. of France was induced by the Milanese regent, Lodovico Sforza, to invade Italy, and had himself crowned king of Naples. Meanwhile, Lodovico had murdered and succeeded his nephew, and he now raised Lombardy against Charles, who with difficulty got back to France in 1495. He had caused the expulsion of the Medici, and Florence was again a republic, in which for a time Savonarola's influence was all-powerful. But, of more consequence than this, Charles's expedition had shown the way to others, and inspired an ambition which, under his immediate successors, cost France dear. In 1499 Louis XII. subdued Milan; in 1501 Ferdinand the Catholic tricked him out of Naples, which the two had joined to conquer, and once more united the Two Sicilies under one crown.

The century thus begun is the most disastrous in Italian history. In Northern and Central Italy the French armies held their own against the pope and his allies until the year 1512, when their young general, Gaston de Foix, fell in victory before the

walls of Ravenna. They were then expelled for the moment; but Italy had no long rest. The rivalry of the Emperor Charles V. and Francis I., which makes the principal part of European history during this period, filled the land with the clash of foreign arms; while her own rulers, striving each to snatch an advantage from the confusion, added to the country's distractions. The papacy was a gainer from the struggle. The conquests of the Borgias passed to the holy see; and Julius II. succeeded in humbling Venice, and then in driving the French out of Lombardy in 1512. In 1515 Francis regained Milan, but in 1524 his forces were expelled from Italy by the emperor, and in 1525 the French king was taken prisoner at Pavia. In May 1527 occurred the sack of Rome by a body of troops of the empire, Lutherans and Spaniards. The Constable de Bourbon, who had led them, was killed in the assault, but not until February 1528 did the invading force retire. In September 1527 the Medicean Clement VII., who had fled to the castle of St Angelo, was compelled by hunger to surrender. The Medici, who had returned to Florence in 1512, were again driven out, but were restored by arms in 1530. Alexander de' Medici received from the emperor, who was his father-in-law, the title of duke; and in 1570 Cosimo, his successor, was made Grand-duke of Tuscany by the pope. By the peace of Cambrai (1529) Charles had been left master of Italy; his son Philip became its undisputed lord by the peace of Cateau-Cambrésis (1559), though Venice really, and Genoa, Lucca, and the little republic of San Marino nominally, remained independent. Besides Tuscany, there were the duchies of Modena and Ferrara and of Parma and Piacenza, and the rich States of the Church; Spain herself held all the rest of Italy, save Piedmont, which was restored to the dukes of Savoy in the person of Philip's cousin and general, Emmanuel Filibert. This prince also regained Savoy and the province of Nice, which his family had lost; but he removed his capital to Turin, and his house was henceforth Italian. The papacy had been strengthened by the founding of the Jesuit order in 1540, and the establishment of the Inquisition; and the Council of Trent (1545-63) defined the Catholic faith. The territory of the church was further augmented by the absorption of several lapsed fiefs, and the supremacy of the pontiffs was now acknowledged by Venice, who had hitherto recognised no superior to her own patriarch. But Venice was no longer the great state she had been. Her commerce had fallen off since the discoveries of Columbus and Da Gama, and most of her conquests were in the hands of the Turks, to whom, in spite of the victory of the allied fleet at Lepanto (1571), she had been compelled to give up even Cyprus. Her last great achievement, in a war that she had waged at intervals for five centuries, was the conquest of the entire Peloponnesus, in 1684; but in 1715 this fell again into the hands of the Turks. The power of Spain, too, had greatly declined, and besides Masaniello's revolt at Naples (1647) there were risings in Sicily, which gave the island to Louis XIV. for two years. But throughout this period, and until as late as the 19th century, Italy was disposed of by foreign powers, and partitioned as suited their policy. After each of the three European wars of succession, in the 18th century, Italy was subjected to a fresh re-division; but it is not necessary to notice more than the last of these in detail. The services rendered by the House of Savoy against the French, during the war of the Spanish Succession, won for it the island of Sicily and the title of king. The new monarch, Victor Amadeus II., was one of the liberal and enlightened despots of the time; and although in 1720 he was compelled to exchange

Sicily for Sardinia, from which island his successors took their title until 1861, he built up a real kingdom, took the schools away from the Jesuits, and did much to promote the welfare of his subjects. The last war, that of the Austrian succession, in which the Sardinians fought gallantly on the Hapsburg-Lorraine side, ended with the treaty of Aix-la-Chapelle (1748), which left Italy divided as follows: the House of Savoy held Sardinia and Piedmont, with Montferrat and Alessandria, Tortona and Novara; the Austrians retained Milan and Tuscany; the Bourbon Charles III. was king of the Two Sicilies, and his brother Philip, Duke of Parma; the papal territory stretched across the centre of the peninsula to the frontiers of Venice, which survived as a republic until 1797; and finally, Modena and Genoa were placed under the protection of France, to whom the Genoese ceded the island of Corsica in 1755. Italy now enjoyed a brief period of freedom from wars; but her numerous sovereigns were absolute, each within his petty domain, and the despotic policy of the Bourbons, who held nearly all the country, was generally adopted. An honourable exception was Peter Leopold, who was Grand-duke of Tuscany from 1765 until he succeeded to the Austrian empire as Leopold II. in 1790. He instituted many reforms, restricted the power of the priesthood, and suppressed the Inquisition; and to him is owing the reclamation of the fruitful Val di Chiana from a wilderness of pestilent marsh. To the rule of this prince the harsh, jealous oppression of the other sovereigns presents a pitiful contrast. For Italy the long reign of misery and darkness was at last about to pass away—but slowly; the night was not yet past.

The storm of the French Revolution burst in 1792. In 1796 Napoleon entered Italy; in 1797 the Cisalpine, Ligurian, Cispadane, and Tiberine republics, with their capitals at Milan, Genoa, Bologna, and Rome, were formed out of Northern and Central Italy, and Venice and her territory beyond the Adige were bestowed on Austria. The next year Naples surrendered, and was made the capital of the Parthenopæan Republic. The democrats in the cities joyfully welcomed the new doctrines brought by the invading army; but even they soon wearied of a nominal freedom that bestowed chiefly the privilege of sharing the heavy costs of the French wars, and in 1800 Napoleon had to win the peninsula afresh by the victory of Marengo. In 1804 he made himself emperor, and in 1805 he was crowned king of Italy at Milan. The Bourbons were permitted to retain Tuscany and Naples, and the pope was reinstated in the possession of Rome. Naples, however, was given to Joseph Bonaparte in 1806, and to Joachim Murat in 1808; in 1809 Rome was annexed to the French empire, and the emperor's sister Eliza was made Duchess of Tuscany. The Congress of Vienna (1815) restored the map of Italy very much to its former appearance; but the advantages of the new distribution fell nearly all to the House of Austria. Venice was added to the Austrian crown, and Lombardy retained; an Austrian duke was set over Modena; and the Austrian Ferdinand III. received back Tuscany, to which Lucca was to be added whenever the death of Napoleon's Austrian wife, Maria Louisa, should give Parma again to its former Bourbon masters. The only other lasting change was the transference of Genoa to Victor Emmanuel I. of Sardinia. Naples and Sicily were restored to the Bourbons, and the pope was once more put in possession of the States of the Church. The little republic of San Marino was also recognised by the congress.

The period following (1815-70) was in the main a period of absolutism and rigid repression, but

it was the period also of the *Risorgimento* ('re-awakening'). The returned princes adopted in full the policy dictated from Vienna, and strove by all means to crush the rising spirit of independence. The Jesuits, whose order had been suppressed by the pope in 1773, were restored and elementary education placed in their hands, where it was effectually strangled. The legions of Austria filled Lombardo-Venetia, and were at the service of all the petty despots in the other parts of Italy; while a yet larger army of spies was at work in every corner of the unhappy country. The general misery provoked conspiracy, and the revolutionary Carbonari societies sprung up everywhere. But the movement had as yet no directing head. There were risings in Southern Italy in 1820, but they were suppressed in the following year, and the leaders executed; and numerous less important insurrections there, in the period preceding 1846, were easily put down. Other abortive attempts were made in Piedmont, in Lombardy, in Modena and the Romagna, the only result of which was to make the rulers' hands yet heavier on the people. Nor was there thorough unanimity or common action among Italian liberals. The extreme republicans, represented by the party of Young Italy, were headed by Mazzini, whose fiery eloquence and enthusiasm transformed the vague desires of his countrymen into a passionate hope; but his policy-sanctioned methods from which more sober patriots shrank. From Geneva he led a band of refugees to the invasion of Savoy, in 1833, because the new king, Charles Albert, would not enter on a war with Austria; but this wild raid proved an utter failure. Already the wiser minds in Italy looked to Sardinia for deliverance; but the dream of a confederacy, with perhaps the pope as president, was not yet dispelled. Nay, it seemed about to be realised when, in 1846, Pius IX. assumed the tiara, and initiated a series of liberal reforms. Constitutions were granted in 1847 by all the rulers save Austria and Ferdinand II. of Naples; and from the latter a constitution was wrung in the following year. The year of revolutions, 1848, opened with a street massacre by the Austrians in Milan, on 2d January. In February the French Republic was declared, and then in Italy the party of Mazzini was for a moment supreme. Sicily revolted from Ferdinand, and in March Charles Albert declared war on the Austrians, who had been driven out of Milan and Venice. He passed the Ticino, and defeated Radetzky at Goito; but on 25th July the Austrians won the decisive battle of Custoza, re-entered Milan, and placed the country under martial law. In Naples there had been a massacre in May, and on 30th August Messina was bombarded. Meanwhile the pope's heart had failed him. His troops had gone to the help of the Sardinians, but before their surrender he had declared their advance to have been without his leave. The republicans, who had regarded his liberal measures with suspicion and jealousy, now denounced him as a traitor to the cause of Italian freedom. On 15th November his wisest minister, Count Rossi, was assassinated, and Pius fled to Gaeta in disguise. A republic was set up in Rome on 9th February 1849, under Mazzini and two other triumvirs. The Grand-duke Leopold had fled from Florence, but Tuscany refused to join herself to the republic; yet when the sovereign she had invited back returned, his first act, supported by the presence of Austrian troops, was to suppress the constitution. In Piedmont the ultra-radicals, headed by Rattazzi, were now in power, and a fresh campaign against Austria was begun—this time lasting less than four days. On 23d March Radetzky defeated the Piedmontese at Novara. Charles Albert gave up his throne to his

son, Victor Emmanuel II., and died, broken-hearted, at Oporto four months later. Efforts were now made to reduce Rome and Venice. In vain did Garibaldi, who had been called to the defence of Rome, defeat the Neapolitans at Palestrina and Velletri. A French army, under General Oudinot, took the city, after a four weeks' siege, on 2d July. Venice, under the heroic Daniel Manin, bravely kept her enemies at bay until 22d August. The petty sovereigns now came back—the pope last, in April 1850. Rome, occupied by a French garrison, was kept in a state of siege for seven years, and the city never quite recovered its freedom until 1870. Italy's first general effort for freedom had ended in failure: 1848 was a year of unfulfilled visions. But one important gain was effected: the dream of federation was ended, and all men looked now to the House of Savoy, save the few idealists, like Mazzini, who afterwards stood sternly apart from the triumph of compromise.

Victor Emmanuel was faithful to the Italian cause, and persevered in the path of reform on which his family had entered. Sardinia was relieved, by the law which gave the government power to abolish monasteries, from the incubus of an army of idle and ignorant ecclesiastics; a liberal constitution was in force, the press was free, education was spreading, and a measure of religious liberty was enjoyed. In 1853 the Sardinian prime ministry passed into the hands of Cavour, the brain, as Garibaldi was the arm, of the coming struggle. Henceforth he inspired and guided the national movement, until his death in the moment of victory. The Sardinian troops, reorganised by La Marmora, were sent under that general to the Crimea, where they won for themselves honour, and for their country allies amongst the great powers. Cavour made terms with Louis Napoleon, and in 1859 war was declared once more against Austria. The French and Italians won the battles of Magenta and Solferino in June, and then the French emperor, acting independently, agreed to a treaty which left the Austrians in possession of Venetia, from the Mincio eastward. The indignation of the Piedmontese, whose sovereign had, under Cavour's agreement with Louis Napoleon, to give up Savoy and Nice in return for this assistance, was intense; but the states of Central Italy voted their union to the kingdom of Victor Emmanuel, and were annexed in March 1860; and a few days after Southern Italy revolted from Francis II., the son of Ferdinand, the detested Bomba. Garibaldi and his volunteers, their expedition secretly favoured by Cavour, went to the support of the insurrection in May, and in September entered Naples. Cavour, with the consent of Louis Napoleon (who, however, maintained the pope in Rome, because his own position in France was strengthened by his championing the head of the Catholic Church), now sent an army into the papal states, which defeated the pope's troops at Castelfidardo, joined Garibaldi, and helped him to defeat the Neapolitan generals on the Volturno. In October Victor Emmanuel entered the Abruzzi, and Garibaldi resigned his dictatorship and retired to his island-farm. In February 1861 the first Italian parliament met at Turin, and Victor Emmanuel was proclaimed king of Italy. But Rome and Venice were not yet freed, and Cavour died in June of this year. In 1862 Garibaldi raised a body of volunteers to liberate Rome, and, having crossed to the mainland, was defeated at Aspromonte; the blame, however, fell chiefly on Rattazzi, who was then minister, and who had sought to follow Cavour's policy, and to reap the advantage of Garibaldi's expedition, but had neglected to first come to an understanding with France. The expressed sympathy of Europe brought about the

September Convention of 1864, by which Louis Napoleon agreed gradually to withdraw the French troops on Italy's stipulation not to allow an attack on the pope's territory. By the last article of the convention, the capital was removed a step nearer Rome—from Turin to Florence. In 1866 the Austro-Prussian war, in which Italy took but an inglorious part as the ally of Prussia, added to the kingdom the coveted territory of Venice. In the same year the French garrison was withdrawn from Rome, and Mazzini demanded that the city should be captured. In 1867 Garibaldi and his volunteers gained a victory near Rome, and the French returned; the volunteers surrendered in November, and the general was arrested. But after the fall of the empire, in 1870, the new foreign minister of France, Jules Favre, declared the September Convention at an end, and the king, who had only prevented the democrats from moving by arresting Mazzini, was at length free to act. On 20th September he entered Rome, and the emancipation of Italy was completed. The pope retained the Vatican, the church of Sta Maria Maggiore, the Lateran palace, the villa of Castel Gandolfo, with their precincts, and was voted an income of £129,000 out of the revenues of the state.

From 1870 onwards Italy at last free and united began to take her place as one of the great Continental Powers. But initial difficulties stood in the way. Thus a marked inferiority among the people of the south in economic, cultural, and social conditions, and a general deficiency in training for self-government complicated the task of political organisation and consolidation. Beyond this, dissension between Vatican and Quirinal—the spiritual sovereign bearing ill the loss of his temporal power—was a hindrance to security and real unity; as the 'prisoner of the Vatican' the pope might still furnish cause for foreign intervention, while so long as the adherents of the Roman Church were forbidden to take part in national politics—a state of affairs the virtual ending of which only in 1905 was not fully signalled till the appearance in 1919 of the Catholic Italian Popular Party, known after 1924 as the National Catholic Society—there could be no common purpose in the nation. Last of all, almost as a necessity if her independence were to be maintained, Italy was involved in large expenditures for the maintenance of an efficient naval and military force, while scarcely less burdensome were the expenses incurred in building up almost from the beginning a state machinery—ports and railways, roads and canals, drainage and irrigation systems, schools and law courts—to secure the administration, the safety, and the welfare of the nation. But the achievement of political unity, if onerous in certain respects, provided conditions in which economic advance became possible. And the period following 1870 was one of remarkable material progress. As Italy grew in strength so her territorial ambitions developed. In Europe the Irredentists (see *ITALIA IRREDENTA*) sought to achieve a wider unity by adding to the kingdom all those districts where the Italian speech prevailed. In Northern Africa a field was sought for colonial expansion—for a reoccupation of those territories once held in sway by the Roman Empire. Tunis was the national ambition, and its seizure by the French in 1881 threw Italy in exasperation into the arms of Austria-Hungary and of Germany, there being formed in 1882 the Triple Alliance, which, renewed at various times, dominated till the time of the Great War most of the political crises of Europe. By failure in Tunis, however, Italy was not balked of African expansion. In 1885 she seized the port of Massowah on the Red Sea, and established the colony of Eritrea in East Africa, while in 1889 she

set up a protectorate over Abyssinia, and in 1889-92 another over Somaliland. These colonies, however, proved for the most part valueless, and led to war with Abyssinia, the disaster of Adowa in 1896 putting an end to the Abyssinian protectorate. In the next century, nevertheless, Italy persisted in her policy of African expansion, and on a wave of nationalism, claiming that her enterprise was hampered, went to war (1911-12) with Turkey for the possession of Libia (Tripoli and Cyrenaica). By the treaty of Ouchy (1912) she achieved her aim, while Rhodes and the Dodecanese, which islands Italy had occupied in the course of hostilities, she continued to hold as a pledge for Turkey's fulfilment of treaty obligations.

On the outbreak of the Great War Italy refused her active assistance to the Central Powers mainly on the ground that she was obliged to aid her allies of the Triple Alliance only in a defensive war. Maintenance of neutrality, however, she offered to Austria-Hungary in return for the cession of various territories, the greater part of Austrian Irredentist lands figuring prominently in her demands. For promise of similar but more comprehensive rewards she expressed her willingness to join the Entente arms. These conditions, rejected by Austria-Hungary, were accepted by the Allies in the secret Pact of London (1915)—the pact promising also, among other things, recognition to Italy's territorial aspirations in Africa—and on 23d May 1915 Italy entered the war. Partial initial successes were followed by various reverses, and these again by gains on the Carso-Isonzo front in the region beyond Italy's eastern frontier, but no decisive victory was won. Then in October 1917 the Italians suffered disaster at Caporetto, and were driven back to the Piave, from which, however, following their victory with Allied assistance in the battle of Vittorio Veneto (October 1918), they returned to impose terms (4th November) on the Austro-Hungarian armies, whereby not only was all Italian territory to be evacuated but also all the territory named in the Pact of London. The subsequent delimitation of Italian territorial gains resulted in protracted and disturbing negotiations, the counter-claims of Yugoslavia presenting in especial questions of peculiar difficulty. The treaties of St Germain (1919), Rapallo (1920), and Lausanne (1923) in the main determined the position. By these agreements Italy obtained Southern Tyrol ('the Trentino'), Gorizia and Gradisca, Trieste and the greater part of Istria, thus gaining her Irredentist territories and achieving incidentally her natural frontier of the Alps, while she also acquired Zara and district on the Dalmatian coast together with various islands in the Adriatic, and was confirmed, moreover, in her possession of Rhodes and the Dodecanese. In 1924, by agreement with Yugoslavia, Fiume was finally ceded to Italy, while in the same year a treaty was signed with Britain, handing over to Italy the greater part of Jubaland, in accordance with the provision of the Pact of London promising territorial compensations in Africa. Viewed as a whole these gains, though important from the point of view of national defence and patriotism, were of no more than slight economic value.

In the period immediately following the Great War the history of Italy is bound up in the main with the fortunes of Socialism (q.v.). As a force to be reckoned with Socialism in Italy had its origin in the last decade of the 19th century, when, as also later, burdensome taxation and generally onerous economic conditions, especially in the agricultural but also in the manufacturing industries, produced widespread social unrest. Persecution in legal guise was at first the lot of the movement, but in spite of repression, and in the

midst of a growing industrialism, the movement gained in power, and in the early 20th century, under the Liberal governments of Giolitti, who first among Italian statesmen recognised the advent of the *quatrième état*, it added very greatly to its strength. During the Great War the Italian Socialists took up for the most part a strong neutralist and anti-war position, and were emboldened in their attitude as a result of the Russian Revolution (1917). But suppression followed Caporetto, to which military disaster the pacifist propaganda of Socialism was held to have largely contributed, and in the later wave of patriotic feeling which accompanied the recovery and final triumph of Italian arms there was little of countenance for Socialism. The subsequent higgings and bickerings of the Peace Conference, however, not to speak of its disappointments, all added to the economic sufferings and dislocations of post-war days, seemed to many to present an obvious justification of pacifist prophecy by the event, and Socialism in these circumstances achieved a new ascendancy. It was a Socialism infused with Bolshevism, and with repeated strikes, some in the public service. There were riots, lootings, burnings, murders. Large Socialist gains at the 1919 elections, where, as a step towards a complete Communistic régime, the establishment by violence of a dictatorship of the proletariat had been promised, served greatly to aggravate the position. Something in the nature of a terror was established, the country becoming utterly disorganised. Apart from a continuance of former methods of disorder, expropriatory finance was practised in many communes which had been captured for Socialism, while as the culminating point of revolutionary effort an attempt, unsuccessful as it proved in the issue, was made in various industries, both manufacturing and agricultural, to give practical application to the principles of soviet rule. In the face of this situation the government, though prepared to introduce into industry a measure of Socialist control, was passive as a whole, and all the circumstances were present in which Fascismo (q.v.) representing reaction rose to power. With Mussolini (q.v.) as their leader, bands composed for the most part of former soldiers, who had in the first instance (from March 1919) been organised to protest against the 'mutilation' by Socialists and Neutralists of Italy's victory in the Great War, onwards from October 1920 made active war throughout Italy upon Socialism, and in less than a year, by methods outravelling those of their opponents in violence, reduced the Socialist party, already suffering eclipse from its seeming failure to produce the promised revolution, to utter impotence. Thereafter Fascismo, its work of destruction completed, aspired to reconstruct the state. Denouncing the incompetence of the government, it summoned the ministry to resign, and mobilising everywhere its forces, marched (27th October 1922) on Rome to carry its aims by force. A state of siege was proclaimed, but the order was later revoked by the king, revolution being in this way averted. Thereupon Mussolini being sent for by the king, and having formed at his request a government, Fascismo became master of the state. In the first instance Mussolini himself had been a revolutionary Socialist, and Fascismo in its beginnings was a political-revolutionary movement. But in the struggle in which it later engaged with Socialism its character was entirely changed. So its programme when it came to power was nationalist and imperialist, and in the main conservative. More important, its methods were essentially autocratic and undemocratic, a virtual dictatorship was established, government was by order in council and parliament was held in con-

tempt, an armed political force was maintained, freedom was denied to the press, constitutional form and the forms of liberty were ignored—a party conquered the state. Later the pressure of reaction brought promise of return to constitutional rule, but in the event it was by a more rigid enforcement of its order that Fascismo maintained its sway.

The principal materials for Italian history during the Middle Ages will be found in Muratori's *Rerum Italicarum Scriptores* (25 vols. 1723–51; useful 'Indices Chronologici' appeared in 1885), and in the *Archivio storico Italiano* (vols. i. xvi. 1835–51). See also Guicciardini's *Istoria d'Italia*, continued to 1814 by Carlo Botta; Muratori's *Annali d'Italia*; Cesare Balbo's *Sommario*; Bryce's *Holy Roman Empire*; and Villari's *Storia politica d'Italia* (8 vols. 1883 et seq.). For separate periods see Hodgkin's *Italy and her Invaders* (1880–99); Villari's *Barbarian Invasions* (Eng. trans. 1902) and *Medieval Italy from Charlemagne to Henry VII.* (Eng. trans. 1910); Sismondi's *Républiques italiennes du moyen-âge*; Troya's *Storia d'Italia del Medio Evo* (1839–59); Reuchlin's *Geschichte Italiens von der Gründung der regierenden Dynastien* (1859–73); Maurice's *The Revolutionary Movement of 1848–49* (1887); Lemmi's *Origini del Risorgimento* (1906); Bolton King's *History of Italian Unity* (1899); Stillman's *Union of Italy* (1898); Underwood's *United Italy* (1912); Niseco's *Storia civile*; Orsi's *Modern Italy, 1745–1922* (1923); Page's *Italy and the World War* (1921); and Gorgolini's *The Fascist Movement in Italian Life* (1923); Symond's *Renaissance in Italy*, and Von Ranke's *History of the Popes* are important, and as general surveys the works of W. Hunt (1873, in Freeman's 'Historical Course'), and J. P. Trevelyan (1920), and the volume (1923) in 'Nations of To-day' (ed. J. Buchan) are useful. See also the articles on the separate provinces and the great cities (Naples, Venice, &c.), and the works cited there; also the articles on the principal characters in Italian history, and ART, DRAMA, PAINTING, RENAISSANCE.

LANGUAGE AND LITERATURE.—Latin is the subject of a special article. The other ancient languages of Italy have been treated above. Italian is one of the group of Neo-Latin or Romance languages—the direct offspring of the Latin tongue spoken by the Romans. The chief subdivisions of the Neo-Latin group are French, Spanish and Portuguese, Provençal, Rumanian, and Italian. This last retains the closest resemblance to its prototype. The affinity between the Romans and the races of the Cisalpine Peninsula being closer than in the case of the other Latinised peoples, the phonetic changes introduced by them are less profound. The question as to whether the Neo-Latin idioms were much modified by the frequent Teutonic invasions of south-western Europe has given rise to prolonged discussion among philologists; but more recent methods of research seem to establish the fact that the influence of these invaders was slight, the more perfect language of the vanquished having imposed itself on the intellectually inferior conquerors. Neither is modern Italian derived entirely from the so-called 'rustic Latin,' or incorrect speech of the lower orders. The origin of the words which compose the modern tongue may be traced in as many cases to the speech of Cicero and Virgil as to that of the common folk. The differences between the ancient and modern languages are the outcome of the natural evolution of all living organisms which must undergo such changes as are necessary to life and growth. But so overwhelming was the prestige of Latin literature that this natural evolution was looked on with contempt by the learned everywhere. The struggle between the written but dead language and the various forms of the living speech was nowhere so protracted as in Italy, where the influence of Roman traditions and culture was supreme.

During this long period of evolution many dialects sprang up which still preserve their individual

peculiarities. The conformation of the peninsula, its varying climates and soils, and the different origins of the races which inhabit it account for the variety and differences of these dialects. Their seemingly wide divergences are in reality mostly caused by pronunciation and not by structural changes. According to the classification of Caix (in his admirable study *Sui Dialetti d'Italia*), their principal divisions are: (1) In the north and north-west the *Gallic-Italian*—viz. Piedmontese, Lombard, and Emilian or Bolognese, in close affinity to the French in their mode of pronunciation and truncated terminations; (2) the *Venetian*, spoken also in the Italian Tyrol and parts of Dalmatia and Istria. This dialect is soft, harmonious, and more purely Italian. The subdivision of it is the Friulian, which preserves a close resemblance to the ancient Rhetian. (3) In the centre the pure *Italian* dialects—viz. Tuscan, Roman, with the nearly-related dialects of Umbria and the Marches, Campanian, in which Abruzzese and Apulian are included. (4) In the south and south-west the *Ibero-Italian*—viz. Sicilian, spoken also in the extreme south of Calabria and part of Sardinia; Corsican, Sardinian, and Ligurian, or the dialects of the Genoese sea-coast. This last group presents marked traces of the close commercial intercourse with Spain and her long dominion in these parts of Italy.

As early as the 11th century the earlier-matured idioms of France and Provence had already taken shape in an abundant literature of their own which invaded the Italian peninsula, and the much-admired poetry of the troubadours threatened to stifle entirely the humbler growth of the soil. However, in the early part of the 13th century, in the famous centre of social life and culture formed by the brilliant court at Palermo of the Emperor Frederick II. of Hohenstaufen, a school of Aulic (or court) poets sprang up headed by the emperor himself and his friend and secretary, Piero delle Vigne (died 1249). The Sicilian dialect formed the basis of the idiom used, but the large mixture of Latin words, and the too evident imitation of Provençal models, mark this school of poetry as an artificial product. After the death of Manfred, Frederick's unfortunate son (1266), the Sicilian school soon ceased to exist.

In various parts of the mainland more or less successful attempts were now being made to write in the vulgar dialects. Noteworthy is that of St Francis of Assisi and his followers to use the Umbrian dialects in religious lyrics during the 13th century, the most distinguished among this group being Jacopone da Todi (died c. 1306). The sacred dialogues, a primitive form of the mystery play, produced by this same school, may be regarded as the earliest germ of the national drama. An important group of lyric poets flourished in Bologna, then a centre of European learning and civilisation; their chief was Guido Guinicelli (died 1276), praised by Dante (*Purgatorio*, xxvii.) as the father of himself and all other singers of love. The contemporary Tuscan poets wrote philosophical lyrics full of overstrained sentiment, but in wonderfully pure Italian. Chief among them were Guido Cavalcanti (died 1300), the beloved friend of Dante, and the immediate precursor of the latter's lyric style; and Cino da Pistoia, a distinguished jurisconsult and admired sonnet-writer, whose death (1336) was bewailed in verse by the young Petrarch. Fra Guittone d'Arezzo (1215–94) and Francesco da Barberino (1264–1348) wrote didactic allegorical poems and songs; the epistles of the former are noteworthy as the earliest prose writings in the vulgar tongue. Among the leading political and learned men of Florence was Brunetto Latini (1210–94); his best-known work is *Il Tesoretto*,

a kind of allegorical encyclopædia in verse, showing immense erudition. Dante speaks of him as his instructor and master (*Inferno*, xv.). To this time belongs the earliest important collection of prose tales, the *Cento Novelle Antiche*, collected by an anonymous but probably Florentine writer. It is in Tuscany, in the central zone of the peninsula, that the idiom at last takes definite shape in which the varied dialects of north and south are to find their representative type. The man who is to harmonise in a great masterpiece these varied elements of style and language, and to reveal to Italy and the world all the power and compass of the living speech, growth of his native soil, is the Florentine Dante Alighieri (May 1265–1321). Dante's supreme poetic genius and the strength and individuality of his noble character made his influence as great among his contemporaries as it has continued to be through all succeeding ages. Almost contemporary with Dante, and forming with him the triumvirate which makes the 14th century, or 'Trecento,' the golden age of Italian literature, stand Petrarch (1304–74) and Boccaccio (1313–75). Thus Italian literature presents the strange phenomenon that it attains its zenith in its opening period. Petrarch, the precursor of the revival of classic studies which was to give the distinguishing mark to the following century, lives in fame, not by his voluminous Latin works, but by reason of the unequalled beauty of his songs and sonnets written in the despised idiom of the people. If we may say of him that he brought to perfection the language of lyric poetry, so may Boccaccio have the honour of giving form to prose by the language in which he clothed his tales. Around this imposing trio are grouped many lesser stars whose works, though inferior as to substance, are all distinguished by the same simple beauty of style. Francesco Stabile, known as Cecco d'Ascoli, is the author of a strange, semi-scientific poem, *L'Acerba*, in which he severely censures Dante's *Divine Comedy*. He was professor of Astrology at Bologna, and was burned for heresy in 1327. The Florentine Fazio degli Uberti produced, in imitation of the *Divine Comedy*, a long poem, *Il Dittamondo*, a wearisome versified account of imaginary travels; more successful were his graceful lyrics. The imitators of Petrarca during this century are of little importance, the most noted being Giusto da Valmontone (died 1449), author of a collection of lyrics, *La Bella Mano*. Among Boccaccio's followers are Ser Giovanni Fiorentino, author of a collection of tales called *Il Pecorone*, written about 1378, and the more original Franco Sacchetti (1330–99), who gives in his book of anecdotes a familiar and spirited picture of contemporary customs.

The earliest undoubtedly authentic historical work in Italian is the *Chronicle* written by Giovanni Villani, a leader in the commercial and political life of Florence, whose history he relates with vigour and simplicity. He died of the plague (1348), but his chronicle is continued till 1364 by his brother and nephew. The important *Cronaca dei suoi tempi*, by Dino Compagni, describes minutely the party strife in Florence (1300–1). Especially noteworthy for their graceful and pure diction are the letters of the famous St Catharine of Siena (1347–80), and the *Fiorette* of St Francis, a selection by an anonymous author of the sayings and doings of that holy man and his followers.

Though classic antiquity was naturally the source of all culture during the 14th century, still the great men of that age drew their more immediate inspiration from the religious and political movements of their day. The distinguishing mark of the 15th century, on the other hand, is the withdrawal of the cultured class from interest in popular events, and their contempt of the national language

for literary uses. Latin becomes the only acknowledged literary medium. For a more detailed account of all the celebrated Humanists and their various patrons, see Symonds's *Renaissance in Italy*, and Roscoe's *Lorenzo the Magnificent* and *Leo the Tenth*.

This great revival or 'Renaissance' of Greek and Roman culture, which from Italy outwards affected the whole of Europe, was fostered by the splendid protection of the numerous princes whose rule was now gradually taking the place of the turbulent but life-inspiring freedom of the small republics. These patrons and their erudite courtiers have conferred a lasting benefit on posterity by the priceless libraries in whose collecting they vied with each other. Foremost amongst artistic and literary centres was Florence, under her Medici rulers, Cosimo, called Pater Patriæ, and his grandson, Lorenzo the Magnificent, who were the first also to encourage a return to the use of the vulgar tongue among the distinguished writers of their court. Leon Battista Alberti (1406–72) was one of the most zealous advocates for the restoration of Italian. A wonderfully versatile genius, he excelled as architect, poet, and prose-writer both on art subjects and moral philosophy; his most important Italian work is a treatise 'On the Family,' of which the well-known dialogue on the same subject ascribed to Agnolo Pandolfini is supposed to have formed part. Angelo Politian (1454–94), one of the most brilliant ornaments of this court, wrote an exquisite eclogue, *L'Orfeo*, the first secular drama in Italian, although the *Canto Carnascialesco*, or rhyming dialogues sung by masqueraders at carnival time, may be considered an earlier form. Side by side with these are the friends Pico della Mirandola (1463–94), who has, however, left little but the fame of his vast erudition, and Girolamo Benivieni, author of much didactic and devotional poetry, which reflects the teachings of the great reformer and orator Savonarola, the opponent of Pagan culture, whose influence was supreme in Florence from 1489 till his execution in 1498. The two Florentines, Giovanni Rucellai (1475–1526) and Luigi Alamanni (1495–1556), wrote graceful poems in imitation of the Georgics. The revival of classic rhythms, attempted by Claudio Tolomei, has been more successfully carried out in modern times by Carducci (q.v.). In Naples a brilliant school of Latin poets flourished. Pontano (1426–1503) enjoyed much contemporary fame and influence; his more celebrated follower, Jacopo Sannazzaro (1458–1530), is remembered by his pastoral romance, with lyric interludes, *Arcadia*, written in Italian.

But the popular and typical product of this age is the narrative poem, or romantic epic. Rude translations of chivalrous poems from the French and Provençal had long been in use among the populace; the first, however, to ennoble the narrative poem was the Florentine Luigi Pulci (1432–84). His style is comparatively simple and free from Latinisms, and one of the distinctive marks of the romantic school in his work, as in all other literatures, is the breaking down of the classic barrier between the serious and the humorous. Contemporary with him was his more famous competitor, Matteo Boiardo (1434–94), an adherent of the dukes of Ferrara. To the same brilliant court belonged the famous Ariosto (1474–1533), who brought to perfection the romantic epic. In close connection with this new school are the burlesque-writers of the early 16th century. Most polished of these was Francesco Berni (1497–1535); he lived in the service of the Medici popes, and is said to have died of poison given by order of the notorious Duke Alexander de' Medici. Florence was the special home of these flippant and licentious poets, whose wit gave expression to the all-pervading scepticism

and corruption of the age. Antonio Francesco Grazzini, called Il Lasca (1503-84), was the most brilliant of the 'Bernesque' imitators. He excels also as a writer of prose tales in the style of Boccaccio, while his contemporary, Matteo Bandello (c. 1480-1562), is the chief story-teller in Lombardy. A strange variety of serio-comic verse is that written in 'Lingua Macaronica,' or burlesqued Latin, by a monk of Mantua, Teofilo Folengo (1492-1544), under the pseudonym of Merlinus Cocajus. Now mere literary curiosities, these humorous poems were immensely popular in their day.

In the 15th century the corruption and dissensions of her many rulers had reduced Italy to a state of dissolution, which left her an easy prey to foreign invaders, and the 16th century saw the completion of her political ruin. Her literature is trammelled by classic imitation and court servility. A corroding cynicism and want of moral sense are the characteristic note of the greatest writers, foremost among whom is Machiavelli (1469-1527); but his great genius and far-seeing patriotism redeem his defects and ennoble his work. Next to him as historian comes his fellow-citizen, Francesco Guicciardini (1483-1540), who is a model of order and elegance. Every court in Italy had its chroniclers, but many of them wrote in Latin. Among these the most quoted is Paolo Giovio (1483-1552), attached to the papal court for many years.

The secret despatches of the Venetian ambassadors to their senate, from 1500 onwards, form a copious store of vivid and accurate historic information. Paolo Paruta (1540-98) has written a remarkable history of Venice. The growth of the secular drama was rapid at this time. Moulded entirely on classic models as to form, comedies now begin to represent living types and customs, while the tragic style remains stilted and artificial. The great names of Machiavelli and Ariosto are foremost amongst these comedy-writers. Full of wit and originality, mixed with obscenity, are the comedies of the infamous Pietro Aretino (1492-1557), whose celebrated Letters were used by him as a means of blackmailing the princes whom he attacked. One of the most applauded and licentious comedies was written by the Cardinal Dovizi of Bibbiena (1470-1520), *La Calandra*, and represented before Pope Leo X. In the didactic works *Il Cortigiano* of the Mantuan Castiglione (1478-1529), and the *Galateo* of the Tuscan G. della Casa (1503-56), we have models of elegant prose, which preserve for us pictures of the court-life of the times. The learned Cardinal Bembo (1470-1547), who during his lifetime gave the law in all matters of literary taste, did much by example and precept to help in the restoration of the vulgar tongue.

Two biographers are especially famous. Giorgio Vasari (1512-74), himself an indifferent artist, has left us a precious mine of information in his much-quoted *Lives of the Artists*; and unique of its kind is the graphic and picturesque autobiography of the great artist, Benvenuto Cellini (1500-71).

The end of the 16th and beginning of the 17th centuries saw political and religious liberty in Italy crushed under the dominion of the foreign invaders, and the increasing power of the popes. It is an age of decadence in art and literature, language is pompous and verbose, and the themes treated unreal. One name of enduring fame illumines this period, that of the unhappy Tasso (1544-95), a pure and earnest genius, and with him ends the pre-eminence of Italian literature in Europe. The pastoral drama, perfected by Tasso in his *Aminta*, and by his rival Guarini (1537-1612) in his *Pastor Fido*, became widely popular. In 1594 the *Dafne* of Rinuccini

was produced with music, the earliest specimen of the musical drama.

The prolixity of description and abuse of metaphor, already in vogue towards the end of the 15th century, grew to such heights in the 17th century that 'Seicentismo' has remained a synonym for all that is false and exaggerated in style. The Neapolitan Giambattista Marini (1569-1625) is the leader of this school. His great poem, *Adonis*, amid all its grave defects, shows a powerful imagination and masterly ease in versification. Among a crowd of mediocre and servile lyrists, the Florentine Vincenzo Filicaja (1642-1707) is noteworthy for dignity and patriotic feeling. Gabriello Chiabrera of Savona (1552-1637) and his followers, Fulvio Testi of Ferrara (1598-1646), and Francesco Redi of Arezzo (1626-98), imitated with success the Greek lyrists. The imitations of Tasso's great epic were less successful than the parodies. A mock-heroic masterpiece is *La Secchia Rapita* ('The Stolen Pail'), by Alessandro Tassoni of Modena (1565-1638). Of a less playful humour are the satires of the well-known Neapolitan artist, Salvator Rosa (1615-73), conspirator with the famous Masaniello against the Spanish oppressors. The greatest names of this age belong to science. The writings of the foremost of all, Galileo, are models of clear exposition and choice diction. The works of the advanced thinkers of the time, nearly all natives of Southern Italy, and the best known amongst whom is Giordano Bruno (c. 1550-1600), belong to the history of philosophy. Venice still cherishes the name of Fra Paolo Sarpi (1550-1623), the scientist, historian, and opponent of Jesuit doctrines.

The dawn of the 18th century shows a dull level of mediocrity, and a false and affected literary taste, which the authority of the Roman 'Academy of Arcadia' did much to foster. Opponents of the prevailing fashion were the Venetians, Gasparo and Carlo Gozzi, the latter (1722-1806) being especially remembered by his graceful dramatised *Fiabe*. The more important Lombard poet, Giuseppe Parini (1729-99), writes with simple elegance in his satires. Most admired of his own contemporaries was the dramatic poet, Pietro Trapassi, known as Metastasio (1698-1782), poet-laureate and favourite at the imperial court of Vienna; but much greater is now the renown of his contemporary Goldoni (1707-93), who, by a return to the study of popular life and existing surroundings, became the reformer of the stage. To the end of this century belongs also Alfieri (1749-1803), the only great tragic writer whom Italian literature possesses. Roused to a hope of liberty by the great Revolution, Italy was again plunged into despair after the fall of Napoleon by the loss of the semblance of unity which had been given her, and, animated by hatred of the petty tyrants who returned to rule her, she began the long struggle for freedom. All the eminent literary men of this period helped the patriotic cause with their pen, and many suffered exile and imprisonment.

The talented Vincenzo Monti (1754-1828) was the leader of a new return to classic models in his eloquent and flowing poems. Pindemonte (1753-1828) is a noted follower of this school, and the more famous Ugo Foscolo (1778-1827). The most illustrious of the classicists is, however, Leopardi (1798-1837), the greatest Italian lyricist since the days of Petrarch. The tragedies of G. B. Niccolini (1782-1861), full of fiery patriotic allusions, were immensely popular. This classic school in turn gave place to the romantic. The centre of this movement was Milan, and its chief Manzoni (1785-1873), whose *Promessi Sposi* is the only really great historical novel in Italian. Two other noteworthy historical novelists are F. D. Guerrazzi (1804-74),

who took a leading part in the Tuscan revolution of 1848; and Massimo d'Azeglio (1798-1865), one of the foremost political men of his time. More modern and original in style is the interesting novel of Nievo (1831-61), *Confessione di un Ottuagenario*.

Silvio Pellico (1789-1854), who wrote many dramas, is better known by the touchingly natural account of his imprisonment by the Austrians. The romantic school produced no remarkable lyrics but those of Manzoni himself, and, although all over Italy fervent poets sang of freedom, only the satires of the Tuscan Giusti (1809-50) are of permanent value. The more noted of these minor poets are Berchet, Prati, Aleardi, Poerio, and Gabriel Rossetti, connected with English literature through his illustrious children. Belli (1791-1863) in Rome, and Porta (1776-1821) in Milan, are noted poetic writers in dialect. The *Summary of the History of Italy*, by Cesare Balbo (1789-1853), the *History of the Florentine Republic*, by Gino Capponi (1792-1876), the *Universal History*, by Cesare Cantù (1804-95), are noticeable works. Rosmini (1797-1855), Gioberti (1801-52), Mamiani (1800-85) are well-known metaphysical and theological writers. Niccolò Tommaseo (1802-74) is noticeable among critics and essayists for the vast extent of his learning. The eloquence and purity of style of Mazzini's political writings give them also literary value, and along with him among advanced thinkers must be mentioned Romagnosi (1761-1835).

Since the stormy times of her struggle for life, united Italy has produced few literary works of character and originality. The name of the poet Carducci (1835-1907) is, however, one of great distinction. Among the minor lyrists are Rapisardi (1844-1912), Guerrini (Stecchetti, 1845-1918), and Pascoli (1855-1912). Dialect poets of note are Fucini (b. 1843), Pascarella (b. 1858), and Di Giacomo (b. 1860). Arturo Graf (1848-1913) and Ada Negri (b. 1870) are also lyrists. Gabriele d'Annunzio (b. 1864), both in poetry and prose, and Matilde Serao (b. 1856), and Giuseppe Verga (b. 1840), in their novels and stories, belong to the extreme school of realism, while the novelists Farina (b. 1846), Barrili (1836-88), and Fogazzaro (1842-1911) show moderate tendencies. Grazia Deledda (b. 1875) writes stories of Sardinia, and Gerolamo Rovetta (1851-1910) novels of the business class. The vivid work of E. de Amicis (1846-1908), and the charming *Autobiography* of the sculptor Dupré (1817-82) are worthy of notice. Among dramatists are Cossa (1830-81), Ferrari (1822-89), Giacosa (1847-1906), and Cavallotti (1842-98). Arrigo Boito (1842-1918), the composer, was no mean poet. The versatile R. Bonghi (1826-95) wrote interesting essays on various historical and political subjects. The masterly historical works of P. Villari (1827-1919) are well known, as are the philosophical and critical writings of Benedetto Croce (b. 1866). Among later prose-writers of note are Papini (b. 1881), Morselli (b. 1883), and Soffici (b. 1883). In the poetry of Marinetti, Futurism (q.v.) had its origin in 1909.

There is a bibliography by Afstanger, *La langue, la littérature, et les écrivains italiens* (Brussels, 1918). For the language, see D'Ascoli, *Archivio Glottologico*; Caix, *Sulla Storia dei Dialetti d'Italia*; Rajna, *Le Origini dell'Epopea Francese*; Littré, *Histoire de la Langue Française*; Max Müller, *Lectures on the Science of Language*, No. vi.; Petrocchi, *La Lingua d'Italia* (Rome, 1908); Trabalza, *Storia della grammatica italiana* (Milan, 1908); Bertoni, *Italia dialettale* (Milan, 1916); and Hoare, *Italian Dictionary* (1915). For the literature, see Sismondi, *Literature of the South of Europe* (trans. by Roscoe); Hallam, *Literature of Europe*; Adolf Gaspary, *Italienische Literatur* (partly translated by Oelsner); De Sanctis, *Storia della Letteratura Italiana*; Garnett,

History of Italian Literature (1898); the monumental *Storia letteraria d'Italia* (published by Dr F. Vallardi, 1900-18); D'Ancona and Bacci, *Manuale della letteratura italiana* (1903-11); Collison-Morley, *Modern Italian Literature* (1911); Vossler, *Italienische Literatur der Gegenwart* (1914); Croce, *La Letteratura della Nuova Italia* (1914-15); Foligno, *Epochs of Italian Literature* (1920); Grillo, *Early Italian Literature* (2 vols. 1920); and other works in Italian by Rossi (1910), Flamini (1919), Scherillo (1919), and in French by Étienne (1884), Hauvette (1906).

Itasca Lake. See MISSISSIPPI.

Itch, or SCABIES, a skin disease produced by a minute mite (*Sarcoptes scabiei*), which burrows in the epidermis of most parts of the body, but especially about the hands. Its presence is marked by a small scaly elevation of the skin, by eruptions as the papillæ of the cutis are perforated, and by the irritating itching sensation.

The mite itself is white or yellowish, broad and flat, with two pairs of mouth parts, and four pairs of appendages. The males are scarcer and much

smaller than the females, which are just visible to the naked eye. When they have entered the skin they do not leave it, but form tortuous burrows, through openings in which the embryos escape. The mites are passed by contagion from person to person, either by direct contact or by clothes or bedding. It is probably the embryos or larvæ which are usually thus transmitted. The above species also occurs on the horse, Neapolitan sheep, and lion; *S. squamiferus* occurs (causing mange) on dogs, pigs, goats, sheep,

Itch-mite :
Abdominal view of female
itch-mite, magnified 65
diameters.

and apparently also for a short period on man; *S. minor* is also distinguished on cats and rabbits.

The itch was for a while regarded as a specific disease, the mite being unknown. Avenzoar, an Arabian physician of the 12th century, is said to have recognised its true nature. So does Scaliger (1557); and Adams figures the animal in a paper read in 1805 before the Royal Society. Amid some scepticism as to the mite in the early part of the 19th century, M. Gales hoaxed the public by figuring as a substitute for the itch-mite the familiar denizen of cheese. His trick was discovered by Raspail, and the existence of a real mite was more distrusted than ever, till in 1834 Renucci, a Corsican student, again demonstrated its presence and characters. It has been often studied since.

The usual cure for itch is found in baths, with abundant soap, or in rubbing with sulphur ointment. If these be not resorted to, the multiplication of the mite may give more serious trouble.

See ARACHNIDA, ACARINA, PARASITIC ANIMALS, SKIN; Canestrini and Kramer, 'Sarcoptidæ' in *Das Tierreich*, 7 Lieferung (1899); and treatises on Parasites by Leuckart, Küchenmeister, &c.

Ith'aca, now THIAKI, one of the Ionian Islands (q.v.), is a long, narrow strip of land off the north-east of Cephalonia, and lies 20 miles W. of the mainland of Greece. The surface is mountainous (2648 feet), and the coast steep and rocky. Area, 37 sq. m. Wine, currants, and olive-oil are largely grown. Goats are kept. Sponges and coral are fished for. The island is celebrated as the principality and home of Ulysses; but Dörpfeld identified the Ithaca of the *Odyssey* with Leukas (q.v.). Chief town, Vathy.

Ithaca, capital of Tompkins county, New York, is picturesquely situated on Cayuga Lake, near

the southern extremity, and on the slopes of the neighbouring hills, 35 miles NNE. of Elmira by rail. It has a large trade in coal, and a number of foundries, mills, and factories. Ithaca is the seat of Cornell University (q.v.). Pop. 17,000.

Itinerary (Lat. *itinerarium*, derived from *iter*, 'a journey'), the name given by the Romans to a written or pictorial account of the principal roads and routes in the empire, with the stations and distances between them. Of the former class the most important are the *Itineraria Antonini* and the *Itinerarium Hierosolymitanum*. The *It. Antonini* are two in number, one containing the routes through the Roman provinces in Europe, Asia, and Africa, and the other the principal sea-routes. They take their name from the Emperor Antoninus Caracalla, under whom they were published, as corrected up to his time, but they seem to have been originally prepared at an earlier date.—The *It. Hierosolymitanum* was drawn up in the 4th century A.D. for the use of pilgrims from Burdigala (Bordeaux) to Jerusalem. The *It. Alexandri* shows the march of Alexander the Great through Asia. See D'Urban's collected edition of ancient *Itineraria* (1845); and PEUTINGER.

Ito, HIROBUMI, born in 1838, was originally a retainer of the Daijio of Chōshū, worked his way before the mast to London in 1863, and returning two years later, was thenceforward the leading spirit in the transformation of Japan into a great power. He repeatedly visited Europe and the United States, and drafted the constitution (1889). He was four times prime-minister, and was made marquis, prince, and President of the Privy Council. He was assassinated by a Korean at Kharbin, 26th October 1909.

Iturbide, AGUSTÍN DE, was emperor of Mexico (q.v.) in 1822-23.

Itzehoe, the oldest town in Holstein, 40 miles NW. of Hamburg, has an active trade, miscellaneous manufactures, and a pop. of 16,000.

Ivan (i.e. John), the name of four tsars of Russia (q.v.), of whom the fourth, Ivan the Terrible (1530-84), did much for the advancement of his country in arts and commerce, as well as for its extension by arms. He was the first Russian sovereign to assume the title of tsar. He subdued Kazan and Astrakhan, and from his reign dates the first annexation of Siberia. He concluded a commercial treaty with Queen Elizabeth, after the English had discovered (1553) the way to Archangel by sea. But his hand fell with merciless cruelty upon the boyars of his kingdom, and upon some of his towns, as Moscow, Tver, and Novgorod. In the last named some 60,000 people were slain in six weeks. This was, however, during the third period of his reign. The first marks the time during which he was under his mother's guardianship; and the second the era of commercial enterprise and territorial consolidation. Ivan died of sorrow for his son, whom three years before he had slain in a mad fit of rage. See Waliszewski, *Ivan the Terrible* (trans. 1904).

Ivanovo, or IVANOFF VOZNESENSK, the 'Manchester' of Russia, in the government of Vladimir, 210 miles by rail NE. of Moscow. It has been the centre of the Russian cotton industry since the middle of the 18th century. Machinery is also made. Pop. 76,000.

Ivinghoe, a market-town of Buckinghamshire, 38 miles NW. of London. Ivinghoe Beacon (904 feet) belongs to the Chiltern Hills.

Iviza, or IBIZA (anc. *Ebrosus*), the most south-westerly of the Balearic Isles (q.v.), lies 56 miles from the Spanish mainland. It is mountainous, and its coasts are indented by several bays. Area, 228

sq. m. Products are salts, fruits, and fish, with a little lead. The chief town, Iviza, which is fortified, is the see of a bishop. Pop. 6000.

Ivory is the name properly given to the tusks of elephants, a material which consists of that modification of *dentine* or tooth-substance showing in transverse sections lines of different shades running in circular arcs, and forming by their decussation minute lozenge-shaped spaces. By this character, which is presented by every portion of any transverse section of an elephant's tusk, true ivory may be distinguished from every other kind of tooth-substance, and from bone and all artificial imitations of ivory. Although no other teeth except those of the elephant present this characteristic, many other animals, such as the walrus, narwhal, hippopotamus, sperm-whale, &c., possess teeth or tusks which from their large size and from their density can be used for many purposes in the arts for which true ivory is employed. A small proportion of the ivory of European commerce comes from Ceylon, India, Burma, Cochin-China, and the islands of the Eastern Archipelago; but the greater part of the produce of the East is used in the regions of its production. The bulk of the ivory sold in the markets of London, Liverpool, and Antwerp is from the African elephant. A small amount, brittle in quality, is also obtained from northern Siberia under the name of fossil ivory, being the tusks of the extinct mammoth embedded in the frozen soil. African ivory is held in the highest estimation by the manufacturer, on account of its superior density and whiteness. The tusks are of all sizes up to about 180 lb., but some have exceeded 200 lb. in weight.

It has been assumed because of the large slabs of ivory used by ancient artists, some of which are still extant, that they possessed a method of softening, bending, and flattening the substance, the secret of which is now lost. One ancient author indeed mentions a means of softening and bending ivory by means of acid solutions, and various recipes are given by mediæval writers for that purpose; but these are not found practicable. It is alleged that immersion in a solution of phosphoric acid renders ivory pliant and translucent; but that is done at the expense of its texture and elasticity—in short, such treatment deprives the substance of the very qualities which render it valuable.

The use of ivory can be traced to Palæolithic times. On fragments of mammoth tusks which have been picked up in the caves of Dordogne and elsewhere have been found incised drawings of many animals, some now extinct and others no longer inhabiting Europe, executed with marvellous spirit and fidelity. It was a substance distinctive of royal state and authority in ancient monarchies. There still exist examples of ancient Egyptian inlaid ivory and Assyrian ivory carvings. When culture and art were at their height in ancient Greece ivory was lavishly used for carvings, sculpture, and objects of luxury; and many of the greatest and most famous works of Phidias and his fellow-artists were 'Chryselephantine' (q.v.) statues—gigantic works built of plates of ivory and gold, some of the figures reaching a stature of 40 feet. Among the Romans the use of ivory for purposes of luxury was equally extensive; and by them plates of ivory, joined as diptychs or triptychs, were used as writing-tablets. Presents of such diptychs were commonly made by consuls on their appointment to officials within their jurisdiction, and among the treasures of classical times which yet exist are many remains of consular ivories. In the middle ages ivory came into use for ecclesiastical purposes in the form of tablets and diptychs for keeping registers and records, for crucifixes, statuettes of saints, caskets, reliquaries,

croziers, and book-covers; it was also carved into chess-men, combs, and hunting-horns. See books by Maskell (1905); Cust (1908), and Dalton (1909).

Ivory, VEGETABLE, is furnished by the palms, *Phytelephas macrocarpa* and *P. microcarpa*, inhabiting chiefly Ecuador and Colombia. They show affinities to the Screw Pines. The plant throws up a magnificent tuft of light-green pinnate leaves of extraordinary size and beauty, like immense ostrich-feathers, rising from 30 to 40 feet in height. The fruit, which is as large as a man's head, consists of many 4-celled leathery drupes aggregated together, and contains numerous nuts of a somewhat triangular form, each coroso or corozo nut being nearly as large as a hen's egg. The kernels of these nuts when ripe are exceedingly hard and white, in fact they resemble ivory so completely that few names have ever been better applied than that of vegetable ivory. They are in extensive use by turners in the manufacture of buttons, umbrella-handles, and small trinkets. Since 1903 the nuts of the Dum (q.v.), or Doom, Palm (*Hyphene thebaica*), of the Sudan, have been imported for like uses, and found very serviceable.—For another ivory substitute, see CELULOID.

Ivory-black. See CHARCOAL.

Ivory Coast is a term now restricted to the French dependency on the Gulf of Guinea, between Liberia and the (British) Gold Coast, and extending inland to the French Guinea, French Sudan, and upper Volta. It has an area of about 122,000 sq. m., and a pop. of 1,500,000. Bingerville is the capital; Grand Bassam (formerly the capital) is an important trading centre, as is also Assinie.

Ivrea, a town of Piedmont, in the Val d'Aosta, 38 miles NNE. of Turin. Founded in accordance with an injunction contained in the Sibylline Books about 100 B.C., it has a cathedral which is supposed to occupy the site of a temple to Apollo. It was the seat of a Longobard duchy, and under the Carolingians of a marquisate. One of the marquises of Ivrea, Berengar II., became titular king of Italy (q.v.) in the 10th century, and his grandson founded the line of the dukes of Burgundy. Incorporated with the empire in 1018, the town and marquisate were given by Frederick II., in 1248, to the House of Savoy. Pop. 11,000.

Ivry, a village in the French department of Eure, 16 miles NNW. of Dreux. On the Plain of Ivry was fought, 14th March 1590, the famous battle between Henry of Navarre and the armies of the League.—**IVRY-SUR-SEINE**, a south-eastern suburb of Paris, on the Seine, manufactures glass, earthenware, and chemical products; pop. 44,000.

Ivy (*Hedera*), a genus of plants of the natural order Araliaceæ, consisting of shrubs and trees, mostly natives of tropical countries. The flowers have five or ten petals, and five or ten converging or consolidated styles. The fruit is a berry with five or ten cells.—The common Ivy (*H. Helix*) is a well-known native of Britain, and of most parts of Europe, although it is more rare in the northern countries. Its long, creeping, branched stem, climbing on trees and walls to a great height, and closely adhering even to very hard substances by means of aerial rootlets, which it throws out in great abundance along its whole length, acquires in very aged plants almost the thickness of a small

tree. Its 5-lobed, shining, stalked, evergreen leaves, clothing bare walls with green luxuriance, serve to throw off rain, and thus render damp walls dry, contrary to a common prejudice, that ivy tends to produce dampness in walls. In order to accomplish this, however, it requires to be pruned annually, for if allowed to run wild it admits rain to the walls by its projecting branches, and so renders even dry walls damp by preventing evaporation. It injures living trees by constriction when permitted to grow upon them. The flowering branches of ivy have ovate, entire leaves, very different from the others, and do not climb, but project from the climbing branches. Its small greenish flowers are produced in the beginning of winter, and the small black berries swell during winter and ripen in the following April. The berries are eagerly eaten by many birds, although they have a pungent taste, and contain a peculiar bitter principle called *hederine*, and an acid called *hederic acid*; which are also found in a gummy exudation obtained by incisions from the stem, and occasionally used in medicine as a depilatory and a stimulant, and in varnish-making. An ointment made from the leaves is used for curing burns; the application of bruised leaves is serviceable for removing corns. In Egypt the ivy was sacred to Osiris, in Greece to Bacchus (Dionysos), whose thyrsus was represented as surrounded with ivy; the Romans mingled it in the laurel crowns of their poets.

There are numerous varieties of common ivy often planted for ornamental purposes, of which that generally known in Britain as *Irish Ivy*, and on the Continent as *English Ivy*, is particularly esteemed for its large leaves and luxuriant growth. They are distinguished from each other by the form of their leaves, and also by their colour, there being many shades of green and bronze, and not a few with gold and silver blotched leaves. Ivy grows readily from cuttings.—*Osmoxylon amboinense* (*H. umbellifera*), a native of Amboyna, is said to produce a finely aromatic wood; and *Heptapleurum stellatum* (*H. terebinthacea*), a Ceylonese species, yields a resinous substance smelling like turpentine. See Dr F. Tobler, *Die Gattung Hedera* (1912). The POISON IVY is a Sumach (q.v.).

Ixi'ón, a king of the Lapithæ, the father of Pirithous. Unable to find purification on earth for the treacherous murder of his father-in-law, he was taken up into heaven and purified by Zeus. But for attempting to seduce Hera he was chained to a fiery wheel, which rolled for ever in the sky.

Izard, the Pyrenean Ibex. See GOAT.

Ivy, showing the aerial Rootlets.

J

the tenth letter of the English and other modern European alphabets, is an altered form of I. Until modern times the letter I, in all languages written in the Roman character, had stood both for a vowel and a consonant. In Latin, as was stated in the article on I, its consonantal value was that of *y* in *year*. In the earliest Old English MSS. the *y* sound was expressed by I, as in *iung*, young; but in later Old English it was written with G (as *giung*, *geong*, young; *gear*, year), except in foreign proper names, as *Iosep*, Joseph; *Iudeas*, Jews. In German, Dutch, and the Scandinavian languages I as a consonant retained its Latin value. In late vulgar Latin the *y* sound was changed into a sound identical with that expressed by G before *e* and *i*; and this sound underwent various developments in the several Romanic languages (see the article G). As the spelling with I was (except in Italian) retained notwithstanding the change in the sound, and as J has been substituted for consonantal I, the modern pronunciation of J in French, English (which adopted Old French orthography in the 12th century), Spanish, and Portuguese is identical with that of the so-called 'soft *g*'—i.e. it is in English *dzh*, in French and Portuguese *zh*, and in Spanish *ch* (as in German *bach*, English *loch*). In German, Dutch, and the Scandinavian, for similar reasons, the letter is pronounced *y*. In Italian, the *dzh* sound etymologically representing the Latin consonant, I is not expressed by J, but by *gi*, as in *già*, *giusto*; but the letter was formerly (and is still by some writers) used for the *y* sound between vowels, as in *gioja*, now commonly spelt *gioia*. In standard Italian orthography the letter is employed only as a substitute for a double *i* at the end of the words, as in *vizj*.

Although the differentiation in form between J and I now serves to express an important phonetic distinction, it was not invented for that purpose. Its history goes back to the 11th century. In mediæval handwriting, as was said in the article I, the small *i* had a troublesome liability to be confused with one of the strokes of a preceding or following *u*. One expedient for obviating this inconvenience was to put an oblique stroke (afterwards a dot) over the *i*; another was to prolong the letter below the line. The tailed form of *i*, as it did not admit of being joined to a following letter, was naturally used chiefly at the end of words, especially after another *i*; but some scribes used it initially, often before *u*, *n*, *m*. The stroke or dot over the small *i* came to be regarded as an essential part of the letter, and therefore was (needlessly) applied to the tailed form. Hence the tailed *i* was adopted by the printers as *j* (black-letter) and *j*, *j* (roman and italic). In English printing before the 17th century it was rarely used except for Latin, chiefly for the second of two consecutive *i*'s, as in *radij*, *conijcio*. In never occurs in the Bible of 1611, and it is said that the only example in the Shakspeare folio of 1623 is in the word *Ijgge* (*jig*). A capital corresponding to the small

j was unnecessary so long as *j* was never used initially; the roman J and the italic *J*, *j* were invented when *j* was beginning to be appropriated to the consonantal function. In black-letter, and in modern German type, the capital I and J have the same form, though the small letters are distinguished. In English handwriting *J*, the script form of I, is still often used instead of *J* for J.

The practice of using *j* for the consonant and *i* for the vowel was introduced by German and Spanish printers at an early period. It became established in France late in the 16th century, and appears in a few English books printed before 1600; but it did not become general in England until about 1630. The Shakspeare folio of 1623 has only I *i* in the text, but *J* or *J* (always as a consonant) in the large italic of the table of contents, lists of *dramatis personæ*, and page headings. The *Halleluiah* of the Bible of 1611 was changed by later printers into *Hallelujah* (though the New Testament form *Alleluia* was left unaltered); this is the only word in which the English pronunciation of J is *y*. In the alphabetical arrangement of dictionaries, it was in England not till about 1820 that I and J were treated as distinct letters; thus in Johnson's Dictionary *Jam* is followed by *Iambick*. The name of J is in French *ji*; this was adopted in English, but has been altered to *ja*, rhyming with the name of the following letter K. The Spanish name is *jota*, from the Greek *iota*. This is sometimes used also in Italian, but usually the letter is called *i lungo* (long I), from its form. The German name *jot*, formerly *jod*, was adopted from Hebrew.

Jabalpur (*Jubbulpore*), chief town of Jabalpur district, Central Provinces, India, 228 miles by rail SW. of Allahabad. Standing at the junction of the East Indian and Great Indian Peninsula systems, Jabalpur is one of the most important railway stations in India. It is the second commercial town in the Central Provinces, manufactures cotton, carpets, pottery, and ornaments from agate pebbles. Pop. (1877) 55,188; (1921) 108,793. The district of Jabalpur has an area of 3912 sq. m., and a population of 745,685.—The *division*, one of the four into which the Central Provinces are broken up, has an area of 18,965 sq. m., and a pop. of 2,296,508, of whom three-fourths are Hindus.

Jabiru (*Mycteria*), a genus of birds of the Stork family (Ciconiidae); the chief distinction from the storks being that the bill is a little curved upwards. There are four species, which are found in Africa, India, Australia, and South America. The best known is the American Jabiru (*M. americana*), which is found from Mexico southwards to the Argentine Republic. It is a large bird, measuring from 4 to 5 feet in height, with white plumage, except on the head and neck, with a massive bill. The Jabirus of India and Australia are sometimes elevated to the rank of separate genera.

Jablonec. See GABLONZ.

Jaborandi. Under this name a number of drugs, used for their sialagogue and diaphoretic actions, are known in Brazil. In Europe, however,

only the leaflets of *Pilocarpus microphyllus* and other species of *Pilocarpus* are recognised as jaborandi. It is a shrub about 4 or 5 feet high, slightly branched, the branches erect, leaves alternate, long-stalked, imparipinnate, and 1 to 1½ feet long; leaflets opposite, in two up to five pairs, with a terminal leaflet. Each leaflet is about 4 inches long, oval-oblong, very obtuse or emarginate at apex, entire, coriaceous, and containing a number of glands which show as dots against the light. The flowers are in racemes. This species is a native of Brazil. The leaflets contain an alkaloid, pilocarpine, $C_{11}H_{16}N_2O_2$ (the nitrate of which is official), to which the effects of the plant are chiefly due, another alkaloid, jaborine, and two decomposition products of these, named respectively pilocarpidine and jaboridine. There are also present a volatile oil and a bitter substance. Jaborandi was first brought to the notice of medical men in Europe by Dr Coutinho of Brazil in 1874, and since then its action has been very fully investigated by numerous physiologists. When pilocarpine is taken internally there ensue very profuse salivation and perspiration, with depression of the circulation and disturbance of vision. Large doses cause in addition nausea, vomiting, and great muscular relaxation. The salivation and perspiration may be completely arrested or prevented by the administration of atropine. Locally applied to the eye it causes contraction of the pupil, and interferes with accommodation and vision. It is used in iritis, in Bright's disease, and in various conditions where its sialogogue or diaphoretic effects are desirable.

Jacamars, small insectivorous birds of the family Galbulidae, closely related to the Puff-birds or Bucconidae. They have a sharply pointed bill, weak feet with the fourth toe reversible, and brilliant soft plumage. Their headquarters are in tropical S. America. They are in the habit of sitting quietly on the branches and making sudden darts at passing insects, returning to their perch with their capture after the fashion of Flycatchers. The white eggs are sometimes laid in holes in banks, but little is known of this. See P. L. Slater's *Monograph of Jacamars and Puff-Birds* (London, 1879-82).

Jacana, a name applied to birds of the family Parridae, distinguished by the extraordinarily long toes and claws which enable them to walk about on the broad floating leaves of water-lilies and other

aquatic plants. They are widely distributed in the tropics, and always frequent lakes and swamps. There are usually spurs at the wrist. The common Jacana (*Parva jacana*) ranges from Ecuador and Guiana to Bolivia and Argentina, a finely coloured bird, interesting in many ways. It feeds gregariously, and has a remarkable dance-like social display. The male warns the female from the

Common Jacana (*Parva jacana*).

threatened nest, and both parents 'sham wounded.' Among the many other forms are *Hydrallector*,

from Borneo to Australia, which shows in perfection the diving capacities of the Parridae, and the long-tailed Indian Jacana, *Hydrophasianus*, which sometimes occurs at considerable elevations. The eggs of Parridae are characteristically of a glossy olive-brown, buff, or green colour, with close dark lines in a curious scrawl. The *c* in *jacana* is soft.

Jacaranda Wood, a very hard, heavy, brown wood, also called *Rosewood*—though not the true Rosewood of commerce—from its faint, agreeable smell of roses. It is brought from South America, and is produced by several trees of the genus *Jacaranda*, of the natural order Bignoniaceae. Several species of this genus are called *Caroba* in Brazil, and are there accounted anti-syphilitic. Several species of the nearly-allied genus *Tecoma* also have an extremely hard wood, as *T. pentaphylla*, a native of the Caribbean Islands. The Brazilian Indians make their bows of the wood of *T. tozophora* or *Pao d'arco*.

Jacare. See ALLIGATOR.

Jachymov. See JOACHIMSTHAL.

Jacinth, or HYACINTH (Ital. *giacinto*, Lat. *hyacinthus*), a transparent, bright-coloured variety of Zircon (q.v.), of various shades of red, passing into orange and poppy-red. A perfect stone has a peculiar golden lustre mixed with its rich orange, and would formerly have fetched a high price; but the jacinth is no longer in fashion. By the ancients it was highly prized, and many fine intagli were executed in it, notwithstanding its hardness, which exceeds that of chalcedony and its varieties. Antique intagli in jacinth, however, almost invariably exhibit a somewhat rubbed or worn surface, which is believed to be due to the somewhat porous texture of the gem. Jacinth occurs in many basalts, tuffs, and some granitoid plutonic rocks, as, for example, near Expailly in Auvergne, and at Unkel on the Rhine, in Bohemia, Saxony, Tyrol, Norway, the Urals, Tasmania, &c. It is likewise met with in the form of granules and rounded crystals in the beds of certain streams, and in alluvial deposits, as near Expailly, in the Iserwiese, and in certain streams in Ceylon. The jacinth or hyacinth of jewellers is not a zircon at all, but some variety of garnet—generally Cinnamon-stone (q.v.); and sometimes ferruginous quartz, which, from its abundance in gypsum at Compostella, in Spain, is called *Hyacinth of Compostella*.—*Jargoon* is the name given by the Singhalese to another variety of zircon. It is usually gray or colourless, but often shows more or less ill-defined tinges of green, blue, red, and yellow. The surfaces of the crystals have a lustre almost rivalling that of the diamond. It was at one time supposed to be an inferior variety of the diamond, and is still occasionally sold as such.

Jack has been from the beginning generally used in England as the equivalent of John, the most common of Christian names, but it is not a little curious that it is really the French *Jacques* (till the 17th century pronounced as a dissyllable), and so through the Latin *Jacobus* and Greek *Iakōbos* from the Hebrew *Ya'aqōb*, Jacob. Others, however, explain it as a shortened form of *Janikin*, an old diminutive of *Johan*, *Jehan*, or *John*; from the northern forms of which again, *Johnkin* or *Jonkin*, we have *Jockey* and *Jock*. The contempt that follows on excessive familiarity attaches itself in most European languages to the name John and its equivalents; thus we find the Italian *Giovanni*, whence *Zanni*, our *Zany*; the Spanish *Juan*, as *bobo Juan*, 'a foolish John'; the French *Jean*, with its signification in compound terms of fool, cuckold, and the like; and our own vulgarisms, 'every man *Jack*' for all men without distinction, a '*Jack-of-all-trades*,' and '*a Johnny*'

for a man of no particular account. Again, such compounds as '*Jack-fool*,' '*jack-ass*,' a '*jack-pudding*,' '*jack-an-apes*' (with intrusion of *n* for *Jack-o'-apes*), point in the same direction. From the sense of familiarity it came to be used of various implements which served instead of a boy or personal attendant, as in '*boot-jack*' and the kitchen '*jack*' which turns the spit. Somewhat similar are such usages as drinking *jack*, the '*jack*' for the small bowl aimed at in a game of bowls, and for the *knaves* in a pack of cards, as well as for a small pike as opposed to the full-grown fish. Compare '*Jack-a-lantern*,' *Jack* the Giant-killer and *Jack* and the Bean-stalk again show the same sense of familiarity without the accompanying contempt. '*Spring-heeled Jack*' was a name for the Resurrectionists (q.v.); '*Jack the Ripper*' was the undiscovered perpetrator of a series of brutal murders of loose women, who terrorised the east end of London in 1888 and 1889.

Jack, or JACA (*Artocarpus integrifolia*), is a kind of Bread-fruit (q.v.) tree.

Jack. See FLAG.

Jackal (Persian *shaghāl*, Fr. *chacal*), the name of a number of species of the genus *Canis* (see DOG), which are in many respects intermediate between the wolves and foxes. *Canis aureus*, being the most typical and widespread form, sometimes goes under the name of the Common Jackal. It

Common Jackal (*Canis aureus*).

measures about 3 feet in length, one-third of which is occupied by the tail, whilst the height is about 18 inches. The animal's build is strong, the muzzle is more acute than that of the wolf, blunter than that of the fox, and the bushy tail hangs down as far as the heel. The ears are short, less than one-fourth the length of the head, and far apart; the pupil of the eye is round. The colour is difficult to define: its ground-tint is a dirty fawn or grayish-yellow, becoming blacker on the back and sides; the under surface is white, reddish-yellow, or gray, and there are not unfrequently ill-defined dark bands on the shoulders and hind-quarters. The home of this species is the southern part of Asia, from India (including Ceylon) over Persia, Arabia, Palestine, and Asia Minor. Hence it has spread, perhaps following the track of armies, to North Africa, the Morea, and Dalmatia. In its habits as well as in its structure it exhibits characters intermediate between the wolves and foxes; like the former it hunts in packs, like the latter it is nocturnal. When on the chase these animals howl most dismally, and make the night hideous in regions where they abound. The singularly appropriate Arabic name *Deeb* ('howler') has reference to this habit. So far from avoiding the proximity of man, they penetrate into villages in search of offal and carrion, and they will also enter yards, houses, or tents in the most shameless manner, and

carry off whatever takes their fancy, sometimes articles absolutely uneatable. They render a certain amount of service as scavengers and by killing vermin, such as mice, but this is by no means an equivalent for the damage they cause by their depredations in sheepfolds and poultry-yards, as well as orchards and vineyards. In many districts they constitute a veritable scourge, and can only be held in check by their congeners the dogs. They follow the larger carnivores to feed upon their leavings, a habit which has given them the reputation of being 'the lion's providers.' They are extremely cunning, and in oriental fable and proverb take the place of our reynard in this respect. The word 'fox' in the Old Testament probably refers in many cases to them. According to Sir Emerson Tennent, they habitually hide their booty, and if observed will seize some indifferent article and make off with it, as though that were the object of their solicitude, returning to their real spoil at the first convenient opportunity. The skull of certain jackals has a horny outgrowth some half-inch in length, eagerly sought for as a charm. Jackals are readily tamed, and the likelihood that they have given rise to some of the domestic dogs has already been alluded to (see DOG). The Striped Jackal (*Canis lateralis*, *C. adustus*) is a connecting link between the wolf and jackal. The extreme length is a little over a yard, and the height rather less than half this; the pupil of the eye is somewhat elliptical and oblique, the ears widely separated. The species is rather rare, but has a wide distribution in Africa south of the Sahara. The Jackal-wolf (*Canis anthus*) is even more wolf-like than the last, and has been classed by different authors among the wolves or jackals. It is much smaller than the wolf, and inhabits Northern Africa. The Black-backed Jackal (*Canis mesomelas*) is somewhat more fox-like than the others, especially in the form of the head. The general build is low. The ears are large and close together, recalling those of the Fennec (see FOX). The area of distribution of this species extends from Middle Nubia down the east side of the continent to the Cape, and perhaps across to the west coast also.

Jack-a-lantern. See IGNIS FATUUS.

Jackass, LAUGHING. See LAUGHING JACKASS.

Jackdaw (*Corvus monedula*), a species of crow, smaller than the rook and carrion crow, its utmost length being only about fourteen inches. It is black, with purplish wings and tail, and a dark-gray neck. It is a common resident in the British Islands, and is found nearly all over Europe, in many parts of which, however, it appears to be migratory; also in Asia and the north of Africa. It is not found in America. Its food consists of insects, snails, and worms. It builds its nest in holes of cliffs, ruins, and old trees. It frequents towns and villages, often making its nest in a chimney, by dropping down stick after stick till some of them become fixed in their oblique descent; and on these others are piled, affording a firm base for a nest of wool or other soft substance. The jackdaw lays from four to seven (usually five) bluish-white eggs, which are covered with small dark-brown spots. The jackdaw is a social bird. It is easily domesticated, and becomes very pert and familiar. It has considerable powers of mimicry, and may be taught to imitate very exactly the human voice.

Jackson, (1) a flourishing city of Michigan, capital of Jackson county, is on both sides of Grand River, which is here crossed by seventeen bridges (five of iron), 76 miles W. of Detroit, and 37 miles S. of Lansing, at the intersection of several rail-

ways. It has the Michigan Central locomotive-works; and manufactures of automobiles, machinery, farming implements, corsets, &c., besides boots and shoes at the state-prison. There is a flourishing general trade. Within the city limits, and close by, there are several mines of bituminous coal. Jackson was settled in 1830, and became a city in 1857. Pop. (1860) 4799; (1870) 11,447; (1920) 48,374.—(2) Capital of the state of Mississippi, on Pearl River, 45 miles E. of Vicksburg by rail, with regular streets, and houses standing for the most part among gardens. Here, besides the state-house, with a valuable library, are the usual state charitable institutions, and the penitentiary. There is a considerable trade in cotton. Pop. 23,000.—(3) Capital of Madison county, Tennessee, on the South Fork of the Forked Deer River, 107 miles by rail S. by E. of Cairo, Illinois. It is the seat of the Union University, is of some importance as a cotton market, and has planing and other mills and railway shops. Pop. 19,000.

Jackson, Andrew, an American general and seventh president of the United States, was born at Waxhaw on the southern border of North Carolina, March 15, 1767. His father, also Andrew Jackson, was an immigrant from the north of Ireland, who died a few days before his son's birth, and his mother and brother succumbed to the hardships of the revolutionary war. After being admitted to the bar at Salisbury, North Carolina, Andrew removed in 1788 to Nashville, then a frontier settlement, and was appointed public prosecutor. In 1791 he married Mrs Rachel Robards, daughter of Colonel John Donelson, supposing that she had been divorced from her former husband. But the divorce not being legally granted until 1793, Jackson had the marriage ceremony repeated. These circumstances furnished material for malignant attacks, and the irritable Jackson fought several duels, in one of which, after he had a rib broken, he killed his antagonist. In the new state of Tennessee Jackson was a leading man; after helping to frame its constitution, he became its representative in congress in 1796, its United States senator in 1797, and a judge of its supreme court in 1798. This position he held until 1804, when he resigned. He gave some support to Aaron Burr's half-revealed schemes of conquest in the south-west, and when Burr was tried at Richmond in 1807 was still his steadfast partisan.

When war was declared against Great Britain in 1812, Jackson, being major-general of the state militia, offered his services and led 2500 men to Natchez, but General Armstrong, the new secretary of war, ordered him to disband them. Jackson, however, marched them in a body back to Nashville, where soon afterwards, in an affray with Colonel T. H. Benton, he was severely wounded. With his fractured arm still in a sling, the general took the field in September 1813 against the Creek Indians in Alabama. This campaign, in which his military genius was first effectively displayed, was closed by a decisive victory at the Horseshoe Bend of the Tallapoosa River, March 27, 1814. Henceforth he was familiarly called 'Old Hickory.' On May 31 he was made major-general in the regular army, and appointed to command the department of the South. Pensacola in Spanish Florida being then freely used by the British as a base of operations, Jackson took the responsibility of invading Spanish soil, stormed Pensacola, and when the British fleet withdrew marched to New Orleans, which was threatened by Sir E. Pakenham with 12,000 veterans. Jackson made his chief defence 4 miles below the city, where, along a ditch extending from a swamp to the Mississippi, he constructed earthworks. On January 8, 1815, under cover of a fog, Pakenham tried to carry these works by direct

assault, but within half an hour the British were repulsed with a loss of 2600 men, including their commander, while the American loss was but 8 killed and 13 wounded. This battle was remarkable not only for the unprecedented disparity of loss, but for the fact that it was fought after the treaty of peace had been signed at Ghent, December 24, 1814.

In 1818 Jackson again invaded Florida, severely chastised the Seminoles, and executed Arbuthnot and Ambrister, convicted by court-martial, on very slight evidence, of inciting the Indians to war. After the purchase of Florida Jackson was its first governor, but soon resigned, and in 1823 he was again elected to the United States senate. In the next year as a candidate for the presidency he had the highest popular vote, but not a majority. The choice was, therefore, made by the House of Representatives from the three highest candidates, and J. Q. Adams was selected; but when he appointed Henry Clay secretary of state, Jackson and his friends alleged that a bargain had been made, transferring Clay's votes to Adams. In 1828 Jackson was elected, having 178 electoral votes out of a total of 261. The first president from beyond the Alleghanies, he was a typical product of the new democratic era—fearless, honest, but prompt to decide everything for personal reasons. A striking feature of his policy was the sweeping removal of minor officials and filling their places with his partisans. This system was aptly described by Senator W. L. Marcy in 1831: 'To the victor belong the spoils.' Jackson's first cabinet was broken up in consequence of his characteristic but futile effort to compel social recognition of Secretary Eaton's wife by the families of the other secretaries. The second cabinet was in the main composed of abler men. Martin van Buren, who had been secretary of state, was nominated minister to England, but after he had gone abroad his confirmation was defeated in the senate by the casting vote of Vice-president Calhoun. This strenuous advocate of state sovereignty was now openly opposed to Jackson, as was shown at a banquet in 1830, when the president gave his famous toast—'The Federal Union—it must be preserved,' and the vice-president responded with another—'Liberty—dearer than the Union.' Congress readjusted the tariff in 1832, retaining the protective system which had prevailed since the peace of 1815, and against which South Carolina had protested as unconstitutional and oppressive. On November 24, 1832, its state convention adopted an ordinance of Nullification (q.v.). President Jackson's proclamation, prepared by Edward Livingston, who had succeeded Van Buren as secretary of state, ably argued the whole question, and declared a firm determination to execute the laws and preserve the Union. Under the leadership of Clay, congress adopted a compromise tariff in March 1833, and South Carolina repealed its ordinance.

The president's veto power was much more freely used by Jackson than by his predecessors. His most memorable veto was that of a bill to renew the charter of the United States Bank, which became the chief issue in the presidential campaign of 1832. Jackson, having obtained 219 electoral votes out of 286, resolved to destroy the bank by removing the government deposits. Two successive secretaries of the treasury refused to do so, but a third who was not confirmed by the senate issued the order. The senate censured this act as usurpation, but Jackson had a closing triumph when the censure was expunged on January 16, 1837. In his administration the national debt was fully paid in 1835, and the surplus revenue which accumulated was ordered to be distributed to the several states.

In foreign affairs Jackson won credit by enforcing the claims for the spoiliations committed by French vessels during the wars of Napoleon. In 1831 France by treaty agreed to pay \$5,000,000, but afterwards delayed payment. The president then recommended to congress to seize French vessels to make up the amount, and France after a protest paid the claim. Jackson's second term having expired on 4th March 1837, he retired to private life at the Hermitage, near Nashville, whence he still watched with keen interest the great political movements of the time. He died at the Hermitage, 8th June 1845.

The most complete biography is by James Parton (3 vols. New York, 1860). For Jackson's administration, T. H. Benton's *Thirty Years' View*, and Von Holst's and other histories of the United States should be examined. See also the Life by W. G. Sumner (1822), that by Dyer (1891), and that by Bassett (1911).

Jackson, Sir Thomas Graham (1835-1924), architect, born at Hampstead, was educated at Brighton and at Wadham, Oxford, and became a fellow in 1864. He studied architecture under Sir G. G. Scott (1858-61), did much work at Oxford and elsewhere, wrote on Gothic, Byzantine, and Romanesque architecture, Wadham College, St Mary's (Oxford), Dalmatia, &c. He was made A.R.A. in 1892, R.A. in 1896, a baronet in 1913.

Jackson, Thomas Jonathan, an American general, better known as 'Stonewall Jackson,' was born at Clarksburg, West Virginia, 21st January 1824, graduated at West Point in 1846, entered the artillery, and gained two brevets in the war with Mexico. He retired from the army in 1851, and became professor in the Virginia Military Institute, where he was more noted for his conscientiousness and religious earnestness than for his success as a teacher. He took command of the Confederate troops at Harper's Ferry on the secession of Virginia, and commanded a brigade at Bull Run, where his firm stand gained him his *nom de guerre* of 'Stonewall.' Promoted to major-general, in the spring of 1862, in the campaign of the Shenandoah valley, he out-generalled McDowell, Banks, and Fremont, and eventually drove back upon the Lower Shenandoah these three Federal armies, two of them of superior strength to his own. Then, hastening by forced marches to Richmond, he turned the scale at Gaines's Mills (27th June), and, the Confederate capital relieved, returned to defeat Banks at Cedar Run in August. He then seized Pope's depôt at Manassas, and his corps bore the brunt of the fighting in the victorious second battle there on 30th August. On 15th September he captured Harper's Ferry with 13,000 prisoners and 70 cannon, and the next day, after a trying night march, arrived at Sharpsburg, where his presence, in the battle of Antietam, saved Lee from utter disaster. Advanced to lieutenant-general, he commanded the right wing at Fredericksburg (13th December), and at Chancellorsville on 1st May 1863 drove Hooker back within the Wilderness. All next day Jackson was on the march, moving round the flank of the National army; at nightfall he fell upon its right and drove it back on Chancellorsville. Returning from a reconnaissance, his party was fired on by some of his own command, and Jackson received three wounds. His left arm was amputated; but pneumonia set in, and on the 10th May he died. No single death was so severe a blow to either side. See Lives by Dabney (1866), Cooke (1866), his wife (1892), Parton (1893), Henderson (1898), and White (1909).

Jackson, William (1730-1803), musician, was born at Exeter, where, after some years in London, he in 1777 became organist of the cathedral. He

published many songs and canzonets, besides sonatas, dramatic pieces, &c., some of his compositions having great vogue in their day.

Jacksonville, (1) capital of Duval county, Florida, and the principal business town in the state, is on the St John's River, 23 miles from its mouth. The meeting-place of five railways, it is 165 miles by rail E. of the state capital, Tallahassee. The streets are wide and well shaded; there are numerous hotels, chiefly for the accommodation of invalids and winter visitors. The city has a large coast trade, besides an active river trade. The chief exports are lumber and cotton. Pop. (1880) 7650; (1890) 17,201; (1910) 57,699; (1920) 91,558. —(2) Capital of Morgan county, Illinois, stands in a fertile prairie region, at the junction of several railways, 34 miles W. by S. of Springfield. It is a pleasant town, and noted for its schools. Here are the Illinois College (Congregational; founded 1830), the Illinois Female College (Methodist; founded 1847), a conservatory of music, and other educational institutions; and here, too, are state asylums for the blind, the deaf and dumb, and the insane, and an asylum for the idiotic and feeble-minded. There are manufactures of woollens, steel bridges, cigars, &c. Pop. 16,000.

Jacmel, a seaport of Hayti, 30 miles SW. of Port-au-Prince; pop. 10,000.

Jacob (Heb. *Ya'aqob*), one of the three chief Hebrew patriarchs, second son of Isaac and Rebekah, whose history and character are graphically described in the Book of Genesis. He and his family followed Joseph to Egypt, where he lived for seventeen years; and, dying there, he was carried to Hebron for burial. Many see in the history of Jacob (on whom Israel, the name of the nation, was also conferred) an ethnological record rather than a personal one. Mention is frequently made of Jacob both in the Old and New Testaments, and there are also many legends about him in Rabbinical and Patristic, as well as in Mohammedan literature. The names *James*, *Jacques*, *Giacomo* are all, as well as *Jacob* and *Yakub*, various modern derivatives from the Hebrew patriarch's name. See JEWS.

Jacob, Bibliophile. See LACROIX (PAUL).

Jacobabad, a town of Upper Sind, 26 miles NW. of Shikarpur by rail, near the Beluchi frontier, has cantonments, a residency, and accommodation for the trade caravans from Central Asia. Here is the memorial tomb of General John Jacob, commandant of the Sind Horse, who founded the place in 1847, and died here in 1858. Pop. (1921) 10,583.

Jacobean Style. See RENAISSANCE.

Jacobi, Friedrich Heinrich, born the son of a merchant at Düsseldorf in 1743, was trained for a mercantile career, became councillor of finance for the joint duchies of Jülich and Berg, but found time for literary and philosophical pursuits. He maintained an active correspondence with Goethe, Hamann, Bouterwek, and was acquainted with Wieland, Herder, Lessing, Hemsterhuis, and others. In 1804 he was summoned to Munich in connection with the newly-founded Academy of Sciences, of which he became president in 1807. He died at Munich, 10th March 1819. Jacobi was not a systematic thinker; he elaborated no system of philosophy. He had become convinced of the truth of one or two leading ideas; and from the standpoint they gave him he examined the chief modern philosophies that were known in his day. His distinguishing doctrines are these: philosophy as elaborated by the understanding cannot transcend the sphere of sense-given materials, and consequently can never get conviction of the existence of such things as God,

immortality, &c.; but man has yet another faculty whereby he has immediate conviction of the real existence of things—viz. reason; by this faculty we have immediate conviction or belief not only of the reality of objects perceived by the senses, but also of the reality of the highest verities that lie beyond the apprehension of sense. Taking these views for his guidance he successively examined Spinozism, in *Ueber die Lehre des Spinoza, in Briefen an Mendelssohn* (1785); Hume's teachings and Kant's, in *David Hume über den Glauben, oder Idealismus und Realismus* (1787); and Schelling's philosophy, in *Von den göttlichen Dingen und ihrer Offenbarung* (1811). He also expounded his teaching in philosophical romances—*Woldemar* (1779) and *Althwill's Briefsammlung* (1781)—in an *Open Letter to Fichte* (1799), and other occasional writings. His works appeared at Leipzig in 6 vols. in 1812–24. See monographs on him by Kuhn (1834), Zirngiehl (1867), and Harms (1876).

Jacobi, KARL GUSTAV JAKOB, German mathematician, was born at Potsdam, 10th December 1804. He studied at the university of Berlin, and in 1827 was appointed extra-ordinary, and two years later ordinary professor of Mathematics at Königsberg. Jacobi excelled in analytical mathematics; his name is best known from his discovery of elliptic functions. Besides this he did most valuable work in connection with differential equations and the theory of numbers: his name is perpetuated in the theory of determinants. In 1829 he published his most celebrated work, *Fundamenta nova Theoriae Functionum Ellipticarum*, for which he received the medal of the Academy of Sciences of Paris. Most of his other investigations were published in *Crelle's Journal für Mathematik*. Jacobi was acquainted with Gauss, Legendre, Abel, and other great mathematicians of his own day. In 1842 he retired from his chair, owing to ill-health, and settled at Berlin. He died in that city on 18th February 1851. His *Gesammelte Werke* (7 vols.) were published by the Berlin Academy in 1881–91.

Jacobins, the members of a political club which exercised a very great influence during the French Revolution. It was originally called the *Club Breton*, and was formed at Versailles, when the States-general assembled there in 1789. It then consisted exclusively of members of the States-general, all more or less liberal or revolutionary, but of very different shades of opinion. On the removal of the court and National Assembly to Paris this club began to acquire importance. It now met in a hall of the former Jacobin convent in the Rue St Honoré, Paris; the Dominicans of France having come to be known as Jacobins from their chief Paris establishment being that of St Jacques (*Jacobus*) in the Rue St Jacques. Hence the revolutionary association received the name of the Jacobin Club, which was first given to it by its enemies; the name which it adopted being that of the *Society of Friends of the Constitution*. It now also admitted members who were not members of the National Assembly, and held regular and public sittings. It exercised a great influence over the agitation, of which the chief seat and focus was in the capital, and this influence was extended over the whole country by affiliated societies. Its power increased, until it became greater than that of the National Assembly. It formed branch societies or clubs throughout France, of which there were soon not less than 1200. When the National Assembly dissolved itself in September 1791, the election of the Legislative Assembly was mainly accomplished under the influence of the Jacobin Club. Almost all the great events which followed in rapid succession

were determined by the voice of the club, whose deliberations were regarded with more interest than those of the Legislative Assembly. It reached the zenith of its power when the National Convention met in September 1792. The agitation for the death of the King, the storm which destroyed the Girondists, the excitement of the lowest classes against the *bourgeoisie* or middle classes, and the reign of terror over all France were the work of the Jacobins. But the overthrow of Robespierre on the 9th Thermidor 1794 gave also the deathblow to the Jacobin Club. The magic of its name was destroyed; and the Jacobins sought in vain to contend against a reaction which increased daily both in the Convention and among the people. A law of October 16 forbade the affiliation of clubs, and on November 9, 1794, the Jacobin Club was finally closed. Its place of meeting was soon after demolished.—The term Jacobins is often employed to designate persons of extreme revolutionary sentiments. For the *Anti-Jacobin*, see CANNING.

Jacobites (from Lat. *Jacobus*, 'James'), the name given after the Revolution of 1688 to the adherents of the exiled Stuarts—James II. (1633–1701) and his son and two grandsons, James Francis Edward, the Chevalier de St George (1688–1766), Charles Edward (1720–88), and Henry Benedict, Cardinal York (1725–1807). Those adherents were recruited from the Catholics, the Nonjurors, the High Churchmen and Tories generally, discontented and place-seeking Whigs, the Episcopals and Highlanders of Scotland, and the great body of the Irish people. Oxford throughout was a great Jacobite centre, a zealous upholder of 'passive obedience' and the 'divine right of kings'; whilst Cambridge, on the other hand, was all for a Protestant succession. First came the battle of Killiecrankie (1689), where fell Graham of Claverhouse, and the Irish campaign (1690–91), with its battle of the Boyne and the treaty of Limerick; next, in 1696, the Assassination Plot, the chief actor in which, Sir George Barclay, escaped, but for which Sir John Fenwick, Sir William Parkyns, and Sir John Friend were executed. Then in 1715 there was the twofold rebellion—one in the Highlands under the Earl of Mar, another in the Border country under Thomas Forster, M.P., and the Earl of Derwentwater. Both practically ended, in spite of the Chevalier's subsequent landing, on the same day (13th November) with the indecisive battle of Sheriffmuir and the surrender at Preston, where nearly two-thirds of the 1500 prisoners were Scots. Seven nobles were sentenced to death, but only Kenmure and Derwentwater suffered, Nairn, Carnwath, and Widdrington being reprieved, and Nithsdale and Wintoun escaping from prison, as likewise did Forster. Not for the first or the last time, the inferior prisoners fared worse than the principals, twenty-six being executed, while over a thousand submitted to the king's mercy, and petitioned to be transported to the American plantations. Alberoni's expedition to the West Highlands (1719), with its 'battle' of Glenshiel, was a petty affair compared with the '15 or with the nine months' rebellion of the '45, whose hero throughout, as indeed of the whole Jacobite movement, was 'Bonny Prince Charlie.' It opened with his landing in the Hebrides (23d July), and closed with his crushing defeat at Culloden (16th April 1746), intermediate events being the victory of Prestonpans, the capture of Carlisle, the raising of the Manchester regiment, the turning at Derby (6th December), and the victory of Falkirk. This, more than the '15 even, was mainly a Scottish, mainly indeed a Highland, rebellion. The English Jacobites as a body held aloof; and of the chief victims beheaded, one only, Charles Radclyffe (Derwentwater's brother), was an Englishman.

The others were the Earl of Kilmarnock, Lord Balmerino, Sir John Wedderburn, and Lord Lovat. The Earls of Cromartie and Traquair were let off, and nearly a thousand prisoners had their death-sentence commuted to transportation or forced enlistment; but fifty were hanged. In stout old Balmerino's avowal, 'If the Great Mogul had set up his standard I should have followed it, for I could not starve,' we see one type of the Jacobite; another, much baser, was Lovat, who played for a dukedom, whilst hoping to risk nothing, for he sent his son off to fight, and himself stayed at home. The last Jacobite hanged (on 7th June 1753) was Dr Archibald Cameron, brother to Lochiel; and in 1772 the last of the Jacobite heads fell down from its spike upon Temple Bar.

This sketch by no means exhausts the list of notable Jacobites, which comprised at one time or another Jeremy Collier, Sacheverel, Charles Leslie, Bolingbroke, Harley, Ormond, Marshal Keith, Rob Roy, William Law, Bishop Atterbury, Carte, Hearne, Dr King, Patten and 'Murray of Broughton' (the two Judases of the '15 and the '45), Sir Robert Strange, and Samuel Johnson. One remembers the Doctor's words about his pension (1762): 'Now that I have it, I am the same man in every respect that I have ever been; I retain the same principles. It is true that I cannot now curse (smiling) the House of Hanover, nor would it be decent for me to drink King James's health in the wine that King George gives me money to pay for. But, sir, I think that the pleasure of cursing the House of Hanover and drinking King James's health are amply overbalanced by three hundred pounds a year.' There spoke an honest Jacobite, and there too spoke the spirit of the age. Jacobitism might linger on as a tradition among the Nonjurors, the very last of whose bishops died in 1805; but as an active principle it had long since become extinct, the reason of such extinction being less the disasters of its adherents or the worthlessness of the cause than the growing prosperity of the nation at large. *Beati possidentes* had a double application, to subjects no less than to sovereign.

The posthumous Jacobitism of the 19th century—'Charlie o'er the Water nonsense,' as Borrow terms it—was largely an outcome of Scott's splendid romance, *Waverley* (1814); and many, perhaps most of our best-known Jacobite lyrics were composed by post-Jacobite poets—Burns, Scott, Hogg, Lady Nairne, William Glen, Allan Cunningham, &c. The 19th century, which heard mass of requiem said for Prince Charles Edward by a Protestant minister (1888), and which saw the Stuart Exhibition (1888-89), was not without its two Stuart pretenders. They were 'John Sobieski Stolberg Stuart, Count d'Albanie' (1795-1872), and his brother 'Charles Edward, Count d'Albanie' (1799-1880), who were certainly the sons of Lieutenant Thomas Allen, R.N., and claimed that he was the son of the young Chevalier.

S. Terry; the *Culloden Papers* (1815); Hogg's *Jacobite Relics* (1819); R. Chambers's *Jacobite Memoirs* (1834), and *History of the Rebellion of 1745* (1828; 7th ed. 1870); Jesse's *Memoirs of the Pretenders and their Adherents* (1845); Mrs Thomson's *Memoirs of the Jacobites* (1845-46); Dr Doran's *London in Jacobite Times* (1877); W. K. Dickson, *The Jacobite Attempt of 1719* (Scott. Hist. Soc., 1895); Bishop Forbes, *The Lyon in Mourning* (Scott. Hist. Soc., 3 vols. 1895-96); A. Lang's *Prince Charles Edward* (1900); Ravigny, *Jacobite Peersage* (1904).

Jacobites, in Church History. See GREEK CHURCH.

Jacobs, WILLIAM WYMARK, born at London in 1863, was in a savings bank department of the Civil Service, but by *Many Cargoes* (1896) made a name as a humorous writer of nautical and long-shore yarns.

Jacob's Ladder (*Polemonium coeruleum*), a herbaceous perennial plant of the natural order Polemoniaceæ, common in the centre and south of Europe, and found also in the temperate parts of Asia and North America. It has a smooth stem 1½ to 2 feet high, and a terminal panicle of bright blue (sometimes white) wheel-shaped flowers.

Jacobus, a gold coin worth 25s., struck in the reign of James I. (1603-25).

Jacopone da Todi, poet and mystic, is believed to have been born about 1228 at Todi, in the duchy of Spoleto, from an advocate to have turned Franciscan about 1268, to have been imprisoned for satirising Boniface VIII., and to have died in 1306. Next to nothing, however, is known about his life, and many of the poems once thought to be his are now attributed to others. See the 'spiritual biography' of him by Evelyn Underhill (1919).

Jacotot, JEAN JOSEPH, the inventor of the 'universal method' of education, was born at Dijon, in France, on 4th March 1770. In the course of his chequered career he was successively soldier, deputy-director of the Polytechnic School, military secretary, and the holder of various professorial chairs, as of Mathematics, Roman Law, &c. He retired to Belgium in 1815, and three years later was appointed lecturer on the French language in the university of Louvain, and afterwards director of the military Normal School. He died at Paris, 30th July 1840. The fundamental principles upon which his system of education rests are that the mental capacities of all men are equal; the unequal results of education depend almost exclusively upon will; every person is able to educate himself, provided he is once started in the right way; knowledge should be acquired in the first place through instinctive experience, or by the memory. For example, in imparting a knowledge of a language, he began by making the pupil commit to memory a single passage; then he encouraged him to study for himself, first the separate words, then the letters, then the grammar, and lastly the full meaning and import. Jacotot's system has some points of resemblance to Hamilton's (see HAMILTON, JAMES). He expounded his views in *Enseignement Universel* (1823). See Life by A. Guillard (Paris, 1860).

Jacquard Loom, named after the inventor, Joseph Marie Jacquard (1752-1834). See WEAVING.

Jacquemart, JULES (1837-80), French etcher. See ENGRAVING.

Jacquerie, the name given to an insurrection of peasants in France in 1358, when the French king John was a prisoner in England. The nobles called the peasants contemptuously 'Jacques Bonhomme'; hence the word Jacquerie. The rising was caused by long-continued oppression on the part of the nobles. It broke out in the neighbourhood of Paris, but extended to the banks of the Marne and the Oise. The magnitude of the danger forced the nobles to make common cause, and on 9th June the peasants were defeated with great slaughter near Meaux. This put an end to the insurrection. See Siméon Luce, *Histoire de la Jacquerie* (new ed. 1894).

Jactitation of Marriage is a false pretence of being married to another—a wrong for which the party injured could formerly obtain redress by a suit in the Ecclesiastical Court. Jurisdiction in

such suits now belongs to the Probate and Divorce Division of the High Court of Justice; but the suit is very rare in modern practice, the English law being clear enough to enable parties to ascertain without litigation whether they are married or not. In Scotland, where the law is not so clear, the suit of declarator of putting to silence (i.e. putting an end to pretended claims) answers the same purpose as a suit for jactitation. Thus, in the famous Yelverton case (1861) the lady's action for declarator of marriage was met by a cross-action for declarator of putting to silence.

Jade is a popular term which includes substances belonging chiefly to two definite mineral species, *Nephrite* (q.v.) and *Jadeite* (q.v.). The word is derived from the Spanish *piedra de hijada*, or 'stone of the loins.' The Spanish term connotes the belief that jade had curative value in kidney troubles. The same idea is implied in the word *nephrite*, from the Greek *νεφρός*, kidney. It is said that jade was first brought to England from Spanish America by Sir Walter Raleigh. Jade is characterised by possessing extreme toughness combined with beautiful lustre and colouring, and it has a bell-like resonance.

Nowhere is jade used so widely and prized so highly as in China, and the study of jade is as important as that of ceramics and bronzes in appreciating Chinese culture and history. For an account of Chinese jades from the archaeological point of view Professor Berthold Laufer's treatise should be consulted. It contains an admirable series of plates illustrating the uses of the material in stone implements, symbols of sovereign power, writing material, images of the cosmic deities, coins and seals, personal ornaments, amulets, vases, &c., and the illustrations bring out clearly the extraordinary delicacy of the carving in the representations of elaborate landscapes and other intricate subjects. The jades used in China before the Christian era appear to have been quarried in China proper; but for the last two millennia most of the nephrite has been imported from Eastern Turkestan, chiefly from the mountains of Khotan and Yarkand, and the rarer jadeite has been brought from Burma.

Jade is also used to some extent in India, where it is employed in the making of such articles as vases and other ornaments, hilts of swords and daggers, and mouthpieces of pipes. Characteristic of the Indian jades in their encrustation with gold and jewels. Old Delhi jade-work, particularly that done under the Mogul rulers of the 17th and 18th centuries, is now almost priceless.

The jade of New Zealand is known to the Maoris as the *pounamu*, or 'green-stone'; it is found along the west coast of the South Island. They work it into amulets, ornaments, and axe-heads. In New Caledonia and some of the other Pacific islands jade is also used for axe-heads, and thus it is sometimes spoken of as 'axe-stone.'
